Welcome to the 77th EAAP Annual Meeting in Hamburg

Ladies and Gentlemen,

on behalf of the Federal Ministry of Agriculture, Food and Regional Identity (BMLEH), the German Society for Animal Production (DGfZ) and the German Organizing Committee are very pleased to invite you to the **77th meeting of the European Federation of Animal Science (EAAP)**, which will take place from **7 to 11 September 2026** in the lively and historic city of **Hamburg**. Under the general theme "**Shaping resilient livestock systems is key to circular agriculture**", we will discuss innovative approaches and solutions for sustainable and resilient livestock systems. Knowledge-based innovations in the livestock sector are essential for developing resilient, circular agricultural systems that can ensure food security, promote animal health, mitigate the negative effects of climate change and contribute to the achievement of the Sustainable Development Goals.

Not only from Europe, but from all over the world, top-class scientists from various disciplines come together at the EAAP Annual Meetings to exchange ideas, present their latest research findings in 12 Study Commissions and establish new contacts from science and industry. No other conference in the world offers such a scientific exchange and excellent platform in this specialized field as the EAAP conferences. We look forward to welcoming around 1,600 – 1,700 participants from over 60 nations to Hamburg.

Hamburg – the "Pearl of the North" – offers an inspiring setting for the conference with its unique blend of historical architecture and modern flair. The city, characterized by its location on the river Elbe, is a cultural jewel. The Speicherstadt, Hamburg City Hall, the Miniatur Wunderland and over 2,500 town bridges invite you to discover them.

Germany is one of the most important agricultural countries in Europe, with animal husbandry playing a central role. Germany's agricultural diversity is matched by its culinary delights. Its beer culture and the enormous range of different styles of bread are internationally known and highly appreciated. Not to forget the popular German wines.

The conference will be complemented by various social events. Look forward to an unforgettable German Evening during Hamburg Harbour Night – set aboard a ship in one of Europe's largest seaports, featuring hearty regional fare and a truly authentic maritime atmosphere.

Discover the beauty of Northern Germany as well. The Technical Tours offer you plenty of opportunities to do so. Or you may be interested in visiting the Hamburg Wadden Sea National Park, which has been a UNESCO biosphere reserve since 1992 and part of the Wadden Sea World Heritage Site since 2011. Immerse yourself in its stunning landscapes and learn why this area is considered one of the most important tidal ecosystems in the world.

We hope you feel inspired and will be able to attend this important conference and join us in shaping the future of animal husbandry and agriculture.

Dr. Christian Lambertz
Chairman of German Organizing Committee
Hans-Willi Warder
President of the German Society for Animal Production (DGfZ)
Jan - Hendrik Schneider
Federal Ministry of Agriculture, Food and Regional Identity (BMLEH)

Organizers of the 77th Annual Meeting of the European Federation of Animal Science

President

- Christian Lambertz (President) - Research Institute of Organic Farming (FiBL), Frankfurt am Main

Committee

- Jörn Bennewitz - University of Hohenheim
- Bettina Bongartz - German Society for Animal Production (DGfZ), Bonn
- Andriy Getya - DGfZ / ADT Consulting / NUBiP
- Kay-Uwe Götz - Technical University of Munich
- Nicole Kemper - University of Veterinary Medicine, Hannover
- Sven König - University of Gießen
- Björn Kuhla - Research Institute for Farm Animal Biology (FBN Dummerstorf)
- Rudolf Preisinger - EW GROUP GmbH, Visbek
- Reinhard Reents - IT Solutions for Animal Production (vit), Verden
- Peter Sanftleben - MV Research Centre for Agriculture and Fisheries, Gülzow-Prüzen
- Jan - Hendrik Schneider - Federal Ministry of Agriculture, Food and Regional Identity
- Julia Steinhoff-Wagner - Technical University of Munich
- Jens Tetens - University of Göttingen
- Georg Thaller - University of Kiel
- Martin Wähner – DGfZ, Bonn
- Hans-Willi Warder - DGfZ / Osnabrücker Herdbook eG (OHG)
- Klaus Wimmers - Research Institute for Farm Animal Biology (FBN Dummerstorf)

Wir bündeln Wissen

aus allen landwirtschaftlich relevanten Bereichen.

We bring together expertise from all areas of agriculture

The Kuratorium für Technik und Bauwesen in der Landwirtschaft e.V. (KTBL) serves as a network of experts. It collects data and facts that are used, for example, to calculate costs or evaluate measures in the areas of crop management, livestock farming, and energy management. Its target audiences include farmers and veterinarians – as well as government agencies, experts, the business community, and the research and scientific communities. As a scientific association, we promote future-oriented agriculture and livestock farming by advising all stakeholders and providing information. We offer various web applications that can assist with, among other things, the planning and cost estimation of barn construction and animal welfare measures.

The European Federation of Animal Science (EAAP)

The main aims of the EAAP are to promote, by means of active co-operation between its members and other relevant international and national organisations, the advancement of scientific research, sustainable development and production systems; experimentation, application and extension; to improve the technical and economic conditions of the livestock sector; to promote the welfare of farm animals and the conservation of the rural environment; to control and optimise the use of natural resources in general and animal genetic resources in particular; to encourage the involvement of young scientists and technicians. More information on the organisation and its activities can be found at www.eaap.org.

Former Presidents

1949-1961	A.M. Leroy (France)
1961-1967	R. Trehane (United Kingdom)
1967-1972	J.M. Rijssenbeek (The Netherlands)
1972-1978	J.H. Weniger (Germany)
1978-1984	E.P. Cunningham (Ireland)
1984-1990	A. Roos (Sweden)
1990-1996	A. Nardone (Italy)
1996-2000	P. Solms-Lich (Germany)
2000-2004	A. Aumaitre (France)
2004-2008	J. Flanagan (Ireland)
2008-2012	K. Sejrsen (Denmark)
2012-2016	P. Chemineau (France)
2016-2020	M. Gauly (Germany)
2020-2024	I. Casasús (Spain)

Council members

President

- Joël Bérard (Switzerland)

Vice-Presidents

- Sam De Campeneere (Belgium)
- Gunnfríður Elín Hreiðarsdóttir (Iceland)

Council Members

- Peer Berg (Norway)

Alternate Auditor

- Jeanne Bormann (Luxembourg)

Secretary General

- Andrea Rosati

The European Federation of Animal Science (EAAP) has close established links with its sister organizations of American Society of Animal Science (ASAS), American Dairy Science Association (ADSA), Canadian Society of Animal Science (CSAS) and Asociación Latinoamericana de Producción Animal (ALPA) and is also member of the World Association for Animal Production (WAAP).

Industry members

EAAP started in 2023 a new initiative to create closer connections between European livestock industries and the animal science network. Therefore, the “EAAP Industry Club” was shaped with the specific aim of bringing together the important industries of the livestock sector with our European Federation of Animal Science. All companies dealing with animal production (nutrition, genetic, applied technologies, etc.) are invited to join the “EAAP Industry Club” because industries will have opportunity to increase their visibility, to be actively involved in European animal science activities, and to receive news and services necessary to industries. In addition, through the Club, industries will enlarge their scientific network and will receive specific discounts on sponsoring activities.

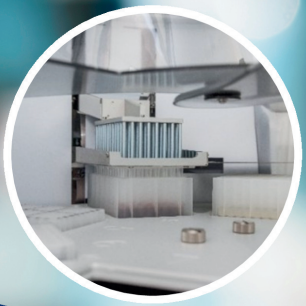
The Industries that already joined the “EAAP Industry Club” are:

The Club gives:

Visibility • Company name and logo at EAAP website and all relevant documents • Slides with name and logo at Official Events • Priority links with EAAP Socials • Invite, through EAAP dissemination tools and socials, people to events organized by your company • Information disseminated through a brand new Industry Newsletter • Networking • Joining the Study Commissions and Working Groups • Suggest topics to be considered for Annual Meetings Scientific Sessions • Organize Professional Panel through the EAAP platforms • One free registration to each Annual Meeting and at every meeting organized by EAAP • Five individual memberships at no cost • Many possible discounts (-30%) to sponsor and to increase company visibility through: EAAP Newsletter, EAAP website, EAAP Annual Meetings and workshops • Support young scientist by sponsoring scholarships named by the company • Co-Organize and sponsor webinars

Make yourself more visible within the livestock industry via the animal science network!
For more information, please contact eaap@eaap.org.

ifn PRECISION FOR BREEDING



RELIABLE GENETIC DIAGNOSTICS FOR SUSTAINABLE ANIMAL BREEDING

Laboratory Services

- High-throughput SNP genotyping
- Parentage verification
- Genetic trait testing
- Hereditary defect diagnostics
- Whole genome sequencing
- Customized genetic projects

Technology & Data

- Illumina Infinium workflow
- Thermo Fisher Axiom workflow
- Commercial & custom SNP arrays
- DNA extraction & sample preparation
- Secure data transfer
- Support for genomic breeding values

"We support sustainable animal breeding through reliable genetic diagnostics, scientific expertise and trusted partnerships."

Young EAAP

What is the YoungEAAP?

YoungEAAP is a group of young scientists organized under the EAAP umbrella. It aims to create a platform where scientists during their early career get the opportunity to meet and share their experiences, expectations and aspirations. This is done through activities at the Annual EAAP Meetings and social media. The large constituency and diversity of the EAAP member countries, commissions and delegates create a very important platform to stay up-to-date, close the gap between our training and the future employer expectations, while fine-tuning our skills and providing young scientists applied and industry-relevant research ideas.

Committee Members at a glance

- Ines Adriaens (President)
- Jana Obsteter (Vice-President)
- Giulia Gislon (Secretary)
- Franziska Koch (National representative)

YoungEAAP promotes Young and Early Career Scientists to:

- Stay up-to-date (i.e. EAAP activities, social media);
- Close the gap between our training and future employer expectations;
- Fine-tune our skills through EAAP meetings, expand the special young scientists' sessions, and/ or start online webinars/training with industry and academic leaders;
- Meet to network and share our graduate school or early employment experiences;
- Develop research ideas, projects and proposals.

Who can be a Member of YoungEAAP?

All individual members of EAAP can join the YoungEAAP if **under 38 years of age**.
Just request your membership form (info@eaap-youngclub.org) and become member of this network!!!

illumina®

Accelerating animal genomic breakthroughs

A global leader in genomics, Illumina delivers the sequencing and genotyping technologies that empower researchers, breeders, and service laboratories to advance agricultural innovation.

Animal genotyping microarrays

Explore custom, off-the-shelf, and consortium-driven microarrays to inform selection and aid breeding decisions.

Animal sequencing solutions

Discover sequencing applications and methods for animal research.

Learn more

Visit the **Illumina booth** to connect with our agrigenomics specialists and discuss how the latest advances in genomics can empower your work.

EXPLANATORY NOTES ON SESSIONS
Abbreviations after the title are (Organising Commission; Session Type)

Commissions are:
Cattle (C), Genetics (G), Health and Welfare (H+W), Horse (H), Insect (I), Livestock Farming Systems (LFS), Nutrition (N), Pig (P), Physiology (Ph), Poultry (Po), Precision Livestock Farming (PLF), Sheep and Goat (S+G).

Session types are:
Theme Sessions are on key topics in animal science and consist of invited and offered papers.
Industry sessions are led and supported by Industry and comprise invited and offered papers.
Free communications/Bottom-Up: these sessions will be created from submitted abstracts.
Discovery Sessions are invited single/multiple presentations on hot/emerging topics.
Challenge Sessions are free format (workshop, open committee, round table) to debate important issues, not theatre paper presentation.
Early-career scientist's Session.
Project session are sessions based around a project which wants to share its results, often combined with submitted abstracts.
Working Group sessions are the results of an EAAP working group.

TWIST BIOSCIENCE

Precision DNA tools for a changing agricultural landscape

The Twist FlexPrep™ UHT Library Preparation Kit simplifies NGS library prep enabling you to get the most out of your sequencing setup. Whether you're working on large-scale studies, complex sample sets, or just looking to reclaim time in the lab, FlexPrep gives you:

- Scalable prep - up to 1,152 samples!
- Compatibility with manual or automated workflows
- Integrated sample normalization with `Normalization by Ligation™
- Reduced consumable usage compared to standard workflows

Trusted by researchers across AgBio, Population Genomics, and more!

Growing excellence through innovation.

Explore EW Group

Innovation begins where the value chain does. A family-owned life sciences holding present in more than 165 countries, the EW Group advances the resilient, resource-efficient genetics and animal health that underpin sustainable, circular livestock systems.

Proud sponsor of the 77th EAAP Annual Meeting in Hamburg!

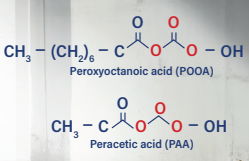
EW GROUP

BIOSECURITY | OXIDATIVE DISINFECTION TECHNOLOGY

ADVANCED CHEMISTRY. PROVEN PERFORMANCE.

Dual-peracid technology delivering powerful, reliable and sustainable hygiene for pig and poultry production.

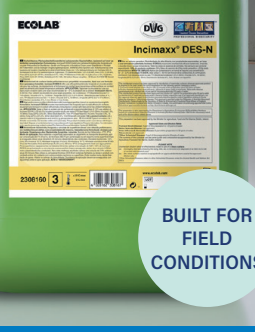
SYNERGISTIC PERACID SYSTEM



Peroxyoctanoic acid (POOA)

Peracetic acid (PAA)

SYNERGY
Superior oxidative power and efficacy vs. single-acid systems



BUILT FOR FIELD CONDITIONS

SUPERIOR FOAM. SUPERIOR DISINFECTION.

SCIENCE-BACKED FORMULATION | PROVEN EFFICACY UNDER FIELDS CONDITIONS | SAFE USAGE

WHERE HEALTH BEGINS

Incimaxx® DES-N

Dual-peracid oxidative disinfection with validated broad-spectrum efficacy

SYNERGISTIC PERACID SYSTEM (PAA+POOA)

- Enhanced oxidative power vs. single-acid systems
- Improved penetration of microbial structures
- Sustained efficacy though higher stability
- Consistent performance in field conditions

MODE OF ACTION

- Membrane disruption
- Enzymatic inactivation
- DNA/RNA oxidation

Multi-target disinfection reducing resistance risk

BPR-ALIGNED EFFICACY

- Bacteria, yeast, fungi
- Mycobacteria
- Enveloped & non-enveloped viruses
- Bacterial spores

Broad-spectrum efficacy across all relevant microorganisms

FIELD PERFORMANCE

- Effective even at low temperatures
- Reliable under practical application conditions
- Suitable for foam and spray systems

FOAM-ENHANCED DISINFECTION PERFORMANCE

- High foaming capacity ensures uniform surface coverage
- Extended contact time on vertical surfaces
- Improved adhesion on complex farm structures
- Optimised interaction between active compounds and contaminants

More consistend and effective disinfection in real farm condictions

RESIDUES

- Breaks down into oxygen, water and organic acids
- No heavy metals
- Chlorine-free

USE & DOSAGE

1-3% for bactericidal, yeasticidal, virucidal (full virucidal) and bacterial spores
5% for mycobactericidal and fungicidal activity

Contact time: 5-30 minutes

Use biocides safely. Always read the label and product information before use.

CID LINES
An Ecolab Company

Brill | Wageningen Academic – Back at EAAP

Brill | Wageningen Academic is a specialist publisher for the life sciences, with a strong focus on agriculture, food and nutrition, animal and veterinary sciences, environmental sciences, and sustainability. Rooted in the internationally recognized expertise of Wageningen University & Research, the imprint has been connecting researchers, practitioners, and policymakers with high-quality scientific publishing since 2002.

Our publishing program includes peer-reviewed journals, books, and conference proceedings, as well as OASES, an intuitive platform for conference abstract submission and peer review. We are particularly proud to publish leading journals such as *Journal of Insects as Food and Feed*, *Comparative Exercise Physiology*, *Beneficial Microbes*, *Behaviour*, *Open Agriculture*, *and many others*.

As part of the De Gruyter Brill publishing group, we combine specialist expertise in the life sciences with global reach and a strong commitment to supporting the research community. We look forward to meeting delegates at EAAP and discussing publishing opportunities - from journals and books to conference proceedings and Open Access.

Come to our booth, browse through our titles and discuss your ideas and publishing plans with us!

TURNING DATA INTO BREEDING SUCCESS

- Integrated database containing phenotypes, genotypes and pedigree information
- Large scale single step evaluation for 60 traits in dairy cattle
- New data sources: MIR, sensor data, efficiency data
- Similar services for other species: sport horses, sheep and goats, pigs

vit
IT-Solutions for Animal Production

vit – Precision Breeding, powered by Data.

Scientific programme

Session 1. Breeding for reduced methane, feed efficiency, resiliency and its potential consequences

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Pszczola, Egger-Danner - Commission(s): G - Session Type: Industry session

Theatre Session 1

Impact of Methane Data Processing Pipelines on Genetic Variance Component Estimation **148**
C. I. V. Manzanilla-Pech, A. E. Van Breukelen, V. Milkevych, O. Gonzalez-Recio, B. Gredler-Grandl, R. F. Veerkamp, Y. De Haas

Genetic parameters for longitudinal CH_4 and CO_2 concentrations from sniffer sensors in automatic milking systems **149**
J. M. Mbuthia, M. Stassen, S. König

Genetic parameter estimation for methane (CH4), carbon dioxide (CO2) and oxygen (O2) production in first parity Holstein cows **150**
S. M. F. Cunha, F. S. Schenkel, F. Miglior, C. F. Baes

Genetic parameters of sniffer-based enteric methane concentration in dairy cows **151**
N. Saedi, R. B. Stephansen, T. M. Villumsen, M. S. Lund, V. Milkevych, P. Løvendahl

Exploring the uniqueness of the genetic architecture of estimated methane emissions in Angler cattle based on existing prediction equations **152**
K. Schröder, G. Thaller, L. Schwarz, M. Brandt, M. Gertz-Gerwinn, N. Gengler, Y. Chen, M. Albers, D. Hinrichs, N. Krattenmacher

Phenotypic and genomic analyses of real and MIR-predicted methane phenotypes in Australian dairy cattle **153**
S. Bolormaa, P. Ho, W. Hsieh, C. Vander Jagt, L. C. Marett, S. R. O. Williams, J. L. Jacobs, J. E. Pryce, R. Xiang

Rumen metabolites as potential indicators to mitigate methane emissions in dairy cattle **154**
C. K. Anene, E. Karaman, G. Sahana

Genetic determinism of feed and water intakes and resilience traits in divergently selected RFI Romane sheep **155**
C. Marie-Etancelin, K. Biard, J. L. Weisbecker, H. Lagarde, C. Coffre-Thomain, F. Tortereau

Circadian feeding patterns in Swiss pigs are highly heritable and associated with feed efficiency **156**
W. Gorssen, C. Winters, N. K. Kadri, N. Khayatzadeh, H. Pausch

Plasma metabolomic signatures differentiate Duroc pigs with divergent feed intake: insights into the molecular architecture of a complex trait **157**
S. Bovo, M. Bolner, C. Lewis, J. Holl, B. Valente, G. Schiavo, F. Bertolini, L. Fontanesi

Functional impact of RNA-Seq derived SNPs associated with feed efficiency in Nellore cattle **158**
M. Teodoro, G. Gubiani, A. Maiorano, L. Mota, A. Cánovas, F. Baldi

Genetic correlation between deep phenotypes and measured phenotypes of feed efficiency **159**
N. Adhikari, A. Van Der Linden, B. Gredler-Grandl, R. F. Veerkamp

Genetic analyses of the relationships among milk yield, feed intake, body weight and energy balance in Holstein Friesians using selected SNP subsets **160**
C. Piefke, C. Schmidtmann, H. Alkhoder, H. Schneider, J. Tetens, J. Bennewitz, G. Thaller

Genetic parameters of residual carbon dioxide as a feed efficiency indicator in Fleckvieh cows **161**
S. J. Burn, B. Fuerst-Waltl, A. Köck, K. Linke, C. Schmid, C. Egger-Danner, W. Zollitsch

Poster Session 1

The impact of selection for methane emissions in dairy cattle on herds with different sizes **162**
C. Labauge, E. Tourrette, M. Eugène, L. Barreto-Mendes, B. Cd Cuyabano

Genetic mitigation of methane emissions in Nordic Red dairy cattle through international data integration and joint genomic evaluation **163**
E. Rius-Vilarrasa, S. Nyman, P. Ask-Gullstrand, T. Kligström, J. I. Ohlsson, M. Bjerring, K. A. Bakke, B. Heringstad, E. Negussie, M. Coffey, F. Miglior, T. M. Villumsen

Mitigation strategies for methane emission in dairy cattle production **164**
K. Msibi

First measurements of methane emissions in the Manech Tête Rousse dairy sheep breed **165**
F. Tortereau, N. Lesueur, G. Affraix, J. M. Astruc, C. Marie-Etancelin

Development of QuickFlux for measuring enteric methane and carbon dioxide fluxes from dairy cattle and their association with dry matter intake **166**
L. Cavani, A. Lago, G. Martinez-Boggio, E. Kebreab, F. Peñagaricano, S. Zimmerman

Genetic and epigenetic hotspots in the Nelore cattle genome associated with residual methane emission **167**
J. Afonso, T. F. Cardoso, J. J. Bruscadin, A. O. De Lima, W. J. D. S. Diniz, J. M. Malheiros, G. B. Mourao, A. Zerlotini, M. Tanurdzic, L. L. Coutinho, L. C. D. A. Regitano

Estimation of genetic parameters of resilience indicators from feeding behavior in the Iberian pig **168**
F. Barceló-Blasco, P. Núñez, N. Ibáñez Escriche, J. Casellas, M. Sánchez-Díaz, S. Negro, L. Varona

Absence of trade-offs between productive traits and immune competence in Dohne Merino **169**
T. Freire, G. Ciappesoni, I. De Barbieri

Activity-based resilience indicators and their relationship with health in dairy cows **170**
L. Büttgen, M. Van Der Sluis, R. De Mol, I. Van Dixhoorn, T. Fernandes Farias, E. D. Ellen

Circadian rhythm of feed intake and heritability estimates in Romane sheep divergently selected for feed efficiency **171**
L. Riaboff, F. Tortereau, K. Biard, H. Lagarde, C. Marie-Etancelin

Heritabilities of Nitrogen Use Efficiency and Nitrogen Loss for Norwegian Red cows vary over the course of lactation **172**
N. Shoukat, A. Kidane, T. K. Belay, T. Meuwissen, B. Heringstad

Combining mechanistic energy allocation and genetic models to explore multiperformance in dairy sheep population **173**
A. Irunal Veedu, F. Douhard, R. Rupp, J. Raoul

Session 2. Challenge session on The third state of the world report on AnGR.

Date: Monday 7 September 2026; 8:30 - 11:45
Chair(s): Danchin, Leroy

Theatre Session 2

The Third State of the World report on Animal Genetic Resources: first insights **174**
G. Leroy, P. Ajayi, P. Boettcher

Reflections on genomic assessment of genetic variation and the future of the breed concept **175**
G. Mészáros, P. Boettcher, D. Ouédraogo, P. Burger, L. Colli, I. Curik, K. T. Gebre, G. Gutierrez Reynoso, G. Leroy, C. Looft, R. Mrode, J. M. Mwacharo, K. Periasamy, A. Stella, Y. Utsunomiya, J. Windig, J. Sölkner, M. Wurzinger

Establishing and scaling up breeding programmes under challenging environments **176**
F. Phocas, J. L. Gourdine, H. Gilbert, V. Ducrocq, J. Raoul, M. Wurzinger

The Evolving Role of the Private Sector in Livestock Breeding **177**
C. Gonzales, Ç. Kaya, G. Cartick

Progress, Gaps, and Future Challenges in Animal Genetic Resources Management in Europe from a National Coordinator Perspective **178**
E. Sosin, N. Svertedal, S. J. Hiemstra, S. Stojanović, J. Tomka, G. Polak, A. Chełmińska

Session 3. European resilient livestock farming systems in a continuously changing world. Part 1

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Sturaro, De Magalhaes, Hadjipavlou - Commission(s): LFS, SG - Session Type: Discovery session

Theatre Session 3

European resilient livestock farming in a continuously changing world - Welcome & introduction **179**
C. Lauridsen, J. Bérard

The New Era is Now: Sustainable Livestock Through Global Collaboration **180**
T. Tiensin

Navigating the Future of Animal Protein in a Changing Global Landscape **181**
E. Gocsik

Ensuring EU feed security and safety in a rapidly changing global environment **182**
R. Hayler, J. Seifert, A. Van Den Brink

Exploring the Missing Middle: From Polarization to Systemic Responsibility in Europe's Protein Transition **183**
M. Moretti

The social and economic challenges to farmers – how can generational renewal be achieved? **184**
K. Wosnitza

EU Policy change related to the vision for agriculture and food, including simplification of EU rules and bureaucracy and comprehensive EU livestock strategy **185**
B. Misonne

European resilient livestock farming in a continuously changing world - Panel discussion **186**
C. Lauridsen

Session 4. Novel infrared (MIR/NIR) approaches on milk, urine, and feces to predict methane emissions and biomarkers

Date: Monday 7 September 2026; 8:30 - 12:15
Chair(s): Manuelian, Martin - Commission(s): C, G - Session Type: Theme session

Theatre Session 4

Comparison of milk mid-infrared spectra and fatty acid-based models for predicting methane emissions **187**
A. Köck, K. Linke, C. Schmid, F. J. Auer, M. Mayerhofer, J. Sölkner, T. Guggenberger, G. Terler, A. Steinwidder, T. Ettle, V. Huber, E. Gerster, C. Egger-Danner

Phenotypic and genetic prediction of methane emissions from milk mid-infrared spectra in Norwegian Red dairy cattle **188**
G. Difford, B. Heringstad, K. Bakke, A. Gjuvsland, G. Gorjanc, J. Jenko

Biological validation of MIR phenotyping for intake, nitrogen efficiency and methane production along the lactation curve in dairy cows **189**
M. Frizzarin, E. Manzocchi, A. M. Reiche, P. Schlegel, G. Lazzari, M. Tretola, F. Schori, F. Dohme-Meier, C. Kasper

Optimizing methane emission prediction using cattle faecal near-infrared spectroscopy across confinement and grazing systems **190**
S. Jeon, D. Andueza, N. Baleret, C. Martin

Faecal NIRS and its ability to predict digestive methane emissions in cattle supplemented with 3-NOP and Asparagopsis taxiformis additives. **191**
D. M. Soares, N. Baleret, D. Parra, G. M. Marques, T. Domingos, R. J. Bessa, C. Martin, D. Andueza

Mid-infrared prediction and genetic analyses of serum metabolites for evaluation of metabolic health in dairy cows **192**
S. Gruber, G. Terler, A. Steinwidder, T. Guggenberger, A. Köck, H. Schwarzenbacher, C. Egger-Danner, B. Fuerst-Waltl, J. Sölkner

Improving milk mid-infrared prediction of dairy cow chronic stress biomarkers using machine learning and deep learning **193**
H. Simon, C. Grelet, S. Franceschini, F. Dehareng

Mid-infrared spectroscopy for large-scale monitoring of urine traits in dairy cows **194**
S. Magro, G. Niero, A. Guerra, M. De Marchi

Prediction of Dry Matter Intake Based on Milk Mid-Infrared Spectra in Holstein Cattle **195**
C. Machefert, S. J. Burn, D. Tulpan, A. Fleming, F. Schenkel, C. Baes, F. Miglior

Decoding lipolysis through individual free fatty FT-MIR model: Enhancing predictive accuracy through real-sample enrichment and advanced algorithms **196**
O. Christophe, D. Vesselko, J. Leblois, F. Dehareng, H. Soyeurt

Using Fourier Transform Infrared (FTIR) Spectra to Investigate GXE Interactions in Danish Holstein Cattle **197**
A. Ö. Şen, E. Karaman, A. J. Buitenhuis

Comparing spectral acquisition methods using a handheld NIR spectrometer for estimating legume content from legume–grass mixtures in Northern Sweden **198**
G. Mantovani, P. Fant, M. Vadronova, D. Parsons, F. Righi, J. Oliveira

BROMEDIR: Development and evaluation of a miniaturized FT-MIR instrument for in-farm milk analysis **199**
C. Grelet, J. Fernández Pierna, Q. Arnould, D. Delhotte, M. Erfan, S. Labib, A. Kishka, E. Magdy, F. Essam, B. Mortada, Y. Sabry, P. Cousin, C. Bromedir, V. Baeten, F. Dehareng

Poster Session 4

Towards a single-step genomic evaluation of cheese-making traits predicted from MIR spectra in eight French dairy cattle breeds **200**
A. Maupome, D. Duclos, M. Gelé, O. Bulot, A. Baur, N. Gaudillère, V. Wolf, D. Boichard, S. Fritz, M. P. Sanchez

From routine reference data to scalable phenotypes: multivariate models combining milk MIR spectra and cow information for metabolic monitoring **201**
A. Mensching, T. Gärtner, J. Braunleder, G. Witzel, K. Donat

Session 5. Circular/Sustainable feeds in the supply chain: alternative feed ingredients - Part 1

Date: Monday 7 September 2026; 8:30 - 12:00
Chair(s): Ranilla García, Ottoboni, Foggi - Commission(s): N - Session Type: Theme session

Theatre Session 5

The efficacy of kenaf leaf meal on the apparent nutrient digestibility and physiological parameters of New Zealand white rabbit bucks **202**
T. C. Kujoana, M. Mabelebele, W. J. Weeks, N. A. Sebola

Performance of rabbit does fed a lactation diet based primarily on agro-food by-products: implications for a circular economy **203**
Z. Volek, L. Zita, P. Šufliarský, L. Pohlová

Dietary evaluation of Pleurotus ostreatus spent mushroom substrate as a sustainable feed ingredient for enhancing performance, egg oxidative stability and ovarian homeostasis in laying hens **204**
I. Brouklogiannis, G. Koutrotsios, I. Poulopoulou, G. I. Zervakis, K. C. Mountzouris

Impact of Moringa oleifera leaf meal supplementation on the growth, nutrient digestibility, and meat quality of quails fed sorghum-canola-based diets **205**
N. A. Sebola, T. C. Kujoana, H. K. Mokoboki, F. Manyeula, M. Mabelebele

Environmental Sustainability and Functional Performance of Alternative Feed Ingredients: An Evidence Synthesis **206**
R. Juel, M. Hegwood, A. Khimasia

Alternative legumes as a sustainable replacement for soybean meal in Iberian pig diets: effects on growth performance and plasma metabolites **207**
A. Román, I. Fernández-Fígares Ibáñez, M. Lachica López, C. García Contreras, R. Nieto Liñán

Alternative legumes as a sustainable replacement for soybean meal in Iberian pig diets: effects on nutrient digestibility, nitrogen balance and inflammatory markers **208**
A. Román, I. Fernández-Fígares Ibáñez, M. Lachica López, C. García Contreras, R. Nieto Liñán

From circularity to practical application: optimizing food industry co-products for pig and poultry feeding **209**
A. Cerisuelo

Hybrid rye inclusion in fattening pig diets to reduce environmental impacts **210**
L. Cappelaere, L. Eastwood, M. P. Létourneau-Montminy

Meta-Analytical Prediction of Metabolizable Energy in Solvent-Extracted Canola Meal pigs Using Chemical Composition **211**
H. Salgado, M. P. Létourneau-Montminy

Dietary former food products modulate fecal microbiota and are associated with improved carcass composition in heavy pigs **212**
M. Tretola, K. Poklukar, M. Skrlep, G. Bee, M. Candek-Potokar

Poster Session 5

Digestibility of mycoprotein derived from Paecilomyces variotii in growing pigs **213**
E. Ivarsson

The impact of replacement imported protein sources with alternative domestic protein feeds in the feeding of fattener pigs on of their fattening, slaughter and economic value **214**
K. Kropiwiec-Domańska, M. Babicz, M. Szyndler-Nędza

Insect protein as a sustainable replacement for soybean meal in diets for growing pigs: effects on growth performance, plasma metabolites and gut inflammation **215**
A. Román, I. Fernández-Fígares, M. Lachica, C. García-Contreras, R. Nieto

Circular protein ingredients from fungal fermentation and blue mussel cultivation: ileal digestibility in broiler chickens **216**
T. Vasileiou, E. Ivarsson, H. Wall

From Winery By-Product to Functional Feed Additive: Polyphenol-Enriched Natural Deep Eutectic Solvents on Antioxidant Defense and Gut Morphology in Meat-Type Quails **217**
G. Pugliese, C. Losacco, V. Roselli, P. Iommelli, L. Piemontese, V. Tufarelli

In vitro large intestinal fermentation of Iberian and Landrace pigs fed lentil, chickpea and soybean diets **218**
A. Román, I. Mateos, N. Merino, C. Saro, A. Díaz, R. Nieto, M. Lachica, C. García-Contreras, M. Lachica, I. Fernández-Fígares, M. J. Ranilla

Sugar beets to support the ensiling of feed for pigs and poultry **219**
C. Visscher, A. Godglück, C. Arnold, C. H. Heuer, U. Bedenk, A. Von Felde, R. Hölscher

Common vetch seeds as home-grown protein feed for growing-finishing pigs **220**
S. Witten, J. Wiskandt, M. T. Machner, R. Bussemas, K. Aulrich

Growth performance, nutrient digestibility, and nitrogen and phosphorus balance and excretion in fattening rabbits fed a diet primarily based on agro-food by-products **221**
L. Zita, Z. Volek, P. Šufliarský, V. Plachý, P. Kočár

Faecal volatile fatty acids production in growing pigs fed local legumes partially replacing soybean meal as main dietary protein source **222**
A. Román, I. Mateos, C. Saro, A. Díaz, N. Merino, C. García-Contreras, M. Lachica, I. Fernández-Fígares, M. J. Ranilla

Session 6. From nutritional recommendation to feeding practice - Part 1

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Manaig, Alvarez-Rodriguez - Commission(s): N - Session Type: Theme session

Theatre Session 6

Effects of high-level inclusion of chopped and pelleted alfalfa on starter intake and growth performance in dairy calves. **223**
R. Colleluori, E. Davis, K. Hare, P. Górka, A. Formigoni, G. Penner

Nutrient intake and growth performance of Holstein calves supplemented with rumen-partially metabolizable methionine analog **224**
P. H. Cavalcante Ribeiro, R. J. De Oliveira, M. E. Pizzo Silva Ferreira, M. Resende Mecchi, D. Domingues Millen

Ruminal fermentation and papillae development of calves supplemented with rumen-partially metabolizable methionine analog **225**
P. H. Cavalcante Ribeiro, R. J. De Oliveira, J. C. Paterno, M. L. Pereira, A. Faria De Toledo, D. Domingues Millen

Hybrid rye as a forage source for Holstein cows around parturition **226**
L. Garcia, B. Brattain, Z. Mcdaniel, F. Cardoso

Carry-over effects of early postpartum protein supplementation on lactational performance, body weight, and nitrogen efficiency in dairy cows **227**
S. E. Räisänen, T. Michou, M. R. Weisbjerg, M. Larsen

Impact of two levels of metabolizable protein and rumen-protected lysine and methionine for primiparous Holstein cows during the transition period and early lactation **228**
E. S. O'Meara-Gossett, D. Martinez Del Olmo, J. Mateos Aguado, P. Mannina, E. Raffrenato, F. Cardoso

Effects of a multi-strain inoculant on alfalfa grass silage quality, digestibility, lactation performance and methane intensity in Holstein cows **229**
G. Omoruyi, R. Scuderi, J. Green, A. Barkley, C. Ballard, C. Villot, S. Morisson, C. Byrne

The effect of alternating concentrate crude protein supplementation on the milk production of spring-calving grazing dairy cows in Ireland **230**
K. M. Mccarthy, K. M. Pierce, Z. C. Mckay, F. J. Mulligan

Effect of partial mixed ration allocation and pellet allocation in the automated milking system on performance of lactating Holstein cows **231**
S. C. Donde, T. J. Devries, G. B. Penner

Effects of barley grain processing methods and dietary starch level on lactating dairy cows dry matter intake, ruminal fermentation, milk and milk component yields **232**
T. Gondo, G. Penner, T. Mutsvangwa, G. Ribeiro

Dietary carbohydrate fractions as modulators of dry matter intake in high-producing Holstein dairy cows: a meta-analytic approach **233**
U. Serbester, P. Y. Bozkaya, A. G. Aydoner

Impact of feeder type on voluntary intake and milk production in lactating dairy cows **234**
Y. Huang, S. Hu, L. Delaby

Quantifying energy expenditure in lactating dairy goats using the doubly labelled water method under pasture and indoor housing conditions **235**
A. Haus, C. Blaschka, J. R. Speakman, A. Patt, J. Hummel, A. Riek

Partitioning of vitamin E in lactating dairy cows at two levels of vitamin supplementation **236**
M. Simoni, S. Pintossi, F. Righi

Poster Session 6

Effect of whey or skim milk as the main protein source in milk replacer on growth performance in dairy calves **237**
P. Górka, W. Budziński

Improving milk yield while reducing diet carbon footprint in European lactating dairy cows. **238**
T. Aubineau, L. Drouet, T. Legot, F. Bedel

Session 7. Scientific Frontiers in Dairy Herd Health, Milk Quality and Adaptive Farm Management

Date: Monday 7 September 2026; 8:30 - 11:45
Chair(s): Cieslak, Montanholi, Kuipers, Niero - Commission(s): C - Session Type: Theme session

Theatre Session 7

Environmental strategies and milk production in European dairy basins : focus on the climate smart french initiative **239**
J. Andurand, E. Castellan, J. Guillemin

Structural consolidation and sustainability priorities in the Polish dairy sector (2004–2026): lessons from a fast-transforming EU dairy region **240**
A. Cieślak, J. Łagoda, J. Sznajder, J. Szczesny, S. Olorunlowu, M. Szumacher-Strabel

Developments in the dairy sector in the Baltic States region: from recent trends to medium-term outlook **241**
S. Zeverte-Rivza, A. Rizojeva-Silava

Recent Developments in Dairy Farming in Slovenia and Croatia **242**
M. Klopčič, M. Špehar

The Ukrainian Meat and Dairy Sector and Agricultural Science under Wartime Conditions: Current Challenges, Adaptation Mechanisms and Development Prospects **243**
I. Ivanytskyi

Description of risk factors and management practices associated to mastitis and milk quality on organic dairy farms across the USA **244**
C. Niño De Guzmán, L. Prada, S. Bellinzoni, P. Muñoz, C. Hernandez, C. Ibarguren, R. Weng, P. De Caso, Q. Kolar, V. Cabrera, B. Heins, R. Lynch, E. Miller-Cushon, G. Schuenemann, P. Pinedo, A. De Vries

Economic opportunities through shorter dry periods for Swiss dairy cows **245**
C. Rudaz, A. Burren, S. Kohler, S. Grossrieder

Iodine in the dairy chain: from measurement to farm management, product characterization and consumer knowledge **246**
G. Niero, S. Censi, C. Mian, M. De Marchi

Association between calving interval, milk yield and early post-partum mortality among Swedish dairy cows **247**
A. Hansson, M. Lindberg, R. Båge, A. Edvardsson Rasmussen, C. Kronqvist

Automatic lameness detection in dairy cows using a limb-specific weighing platform **248**
N. Herrmann, A. Burren, M. Hillen, A. Steiner, S. Kohler

Poster Session 7

Cow hygiene and bedding microbiology in compost-bedded pack dairy systems with and without organic substrate **249**
M. F. Caminati, J. L. Monge, D. Bueno, E. Reinoso

Under construction – an approach to building animal welfare expertise in vocational training **250**
C. Over, S. Ivemeyer, K. Cimer, J. Helmerichs, J. Brinkmann, S. March

The use of chlorophyll extract as post dipping in the photodynamic inactivation of microorganisms **251**
R. Combuca Da Silva Junior, K. Souza Silva Campanholi, R. Aleson Dias Bezerra, W. Caetano, M. Soares Dos Santos Pozza

Integrative Characterization of Feed and Water Microbiomes in Dairy Production Systems **252**
S. Duarte-Coimbra, L. Pérez-Pardal, A. Beja-Pereira

Immunomodulatory Effects of Bacterial Extracellular Vesicles from Wild and ATCC Escherichia coli and Staphylococcus aureus: A Comparative In Vitro Study **253**
M. Penati, D. L. S. Dos Santos, R. I. Lazar, O. Balbi, M. C. Gilioli, I. Maluf, M. Y. R. Cieza, Y. Dadi, G. Salvi, F. Ceciliani, N. C. C. Silva, C. Lecchi, L. G. De Matos

Session 8. Resilient pigs in resilient farming systems – health, welfare and robustness in practice. How to cope with changing expectations and legislation - Part 1

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Arnaud, Morgan, Aluwé - Commission(s): P, HW - Session Type: Theme session

Theatre Session 8

Social Intermittent Suckling: Easing Weaning for Piglets and Sows **254**
L. Fabà, L. Ferreres-Serafini, P. Langendijk, J. F. Pérez, S. M. Martín-Orúe, H. M. J. Van Hees

The future perspectives of increasing within-litter body weight uniformity in pigs **255**
K. Hooyberghs, S. Goethals, W. Gorssen, S. Millet, S. Janssens, N. Buys

Dietary combination of β-galactomannans, plant extracts and monoglycerides improves survival and performance in post-weaning piglets **256**
P. Martín-Atance, S. Carné, M. Verdú, X. Soldevila, J. Estévez

Effect of supplementing gestating and lactating sow with a Citrus-based sensory feed additive on sow reproduction and piglet performance **257**
J. Foglio, J. F. Gabarrou, E. Arnaud

Effects of different combinations of dietary zinc and copper sources on their homeostasis, mitochondrial function, ATP concentrations and antioxidant response in different tissues in post-weaned piglets **258**
J. V. Da Silva Duarte, J. S. Bee Tubin, I. Audet, D. Bueno Dalto

The use of blood biomarkers to evaluate the impact of acute heat stress in piglets and growing finishing pigs **259**
U. M. Mccormack, E. Perez-Calvo, J. Zhang, Z. Wang, S. Wang, A. J. Cowieson

Participatory identification of feasible pig welfare innovations to support resilient farming systems under evolving EU legislation **260**
N. J. Tirchett, E. Garcia Manzanilla, V. A. Moustsen, A. Valros, P. Chevillon, V. Courboulay, P. Ferrari, J. Lorente Martín

Updated Drinking Water Requirements and Key Influencing Factors in Cattle, Pig and Poultry Production **261**
L. De Prekel, A. Van De Sompele, M. Lamerand, K. Goossens

Natural Behaviour and Activity Pattern of Pigs: A comparative study of breeds and environments **262**
M. Wolf, R. Thomsen, M. L. Buus, J. Küper, K. Frölich, I. Czycholl

Changes in body dimensions of Irish sows over 20 years **263**
A. Foley, L. Boyle, K. O'Driscoll, L. Jessiman, E. Baxter

Botanical supplementation: An effective Approach to manage tail biting in pigs farm **264**
C. Maltret, S. Cisse, M. E. A. Benarbia, A. Roques

Ex vivo antimicrobial assay determines in vivo antibacterial activity of glycerides of lauric acid against S. suis **265**
O. Lemâle, T. Meyns, A. Mellouk, N. Vieco-Saiz, M. Jlali, J. Consuegra

Poster Session 8

Plasma lipid dynamics during traditional acorn-based fattening in culled Iberian sows **266**
J. García-Gudiño, C. Barraso, I. Blanco-Penedo, M. López-Parra, M. Izquierdo, F. I. Hernández-García

Implementing new legal requirements for sow housing: factors influencing functional use of an outdoor area in the mating area **267**
S. Geisler, M. Hasler, A. L. Van Asten, N. Kemper, I. Traulsen

Behaviour of fattening pigs in structured pens with outdoor access **268**
A. L. Ehrlich, A. Langehennig-Peristenidou, N. Kemper, T. J. Nicolaisen

Effects of different nesting materials on crushing risk and sow posture changes in a temporarily confined farrowing system **269**
J. Wahmhoff, M. Wutke, A. L. Van Asten, N. Kemper, I. Traulsen

Does the temperature-humidity index affect the growth rate of weaner pigs? **270**
J. Probst, P. Heseker, C. Meyer, S. Götz, S. Schäfers, I. Traulsen, N. Dirksen, N. Kemper

Bone mineral content kinetics in sows across three consecutive lactations as a function of dietary phosphorus during lactation **271**
J. Heurtault, M. P. Létourneau-Montminy, P. Schlegel

Inter-rater reliability of animal-based indicators intended for organic inspections on pig farms **272**
S. Lühken, A. Höhne, A. Schubbert

Turning Carasau bread leftovers into piglet gains: performance and diarrhoea outcomes after full wheat replacement in the diet **273**
G. Bee, R. Ruggeri, A. Loddo, P. Catzeddu, T. Roggio, G. Battacone

Detection and monitoring of several salivary heat stress biomarkers in growing pigs **274**
C. Puigfel-Camarasa, L. Sarri, G. De La Fuente, M. Tor, A. R. Seradj, J. Balcells

From heat stress to genetic resilience: addressing seasonal infertility in Pigs **275**
L. Bordin Temp, N. Galoro Leite, L. Zak, J. Linck Moroni, J. M. Tabet, E. Grindflek, D. Lourenco

Session 9. Rethinking sustainability from a One Welfare perspective

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Blanco-Penedo, Boyle, Kuipers - Commission(s): HW, LFS, C - Session Type: Discovery session

Theatre Session 9

Reframing sustainability for a fairer future for livestock farming: A One Welfare approach **276**
L. Boyle, F. Johansen

Aggregation of indicators for the multifunctionality of mountain dairy cattle farms: a One Welfare approach **277**
A. Zoratti, S. Bovolenta, E. Benedetti Del Rio, S. Sari, L. Bava, A. Tamburini, M. Berton, E. Sturaro, M. Corazzin

Integrating Positive Animal Welfare and One Welfare: A Socio-Environmental Framework for Sustainable Livestock Systems **278**
J. Goracci, I. Blanco-Penedo, M. Battini, I. Antonik, I. Aytemiz Danyer, G. Batikas, X. Boivin, I. J. Boumans, D. Enriquez-Hidalgo, F. A. Galindo-Maldonado, R. García Pinillos, R. Kaura, H. L. Ko, P. Llonch, R. E. Nordquist, R. Yıldız, A. Yıldırım, L. Jung

Bringing animal welfare into sustainability: embedding animal wellbeing in Life Cycle Assessments **279**
I. Kyriazakis, C. Wangui

Development and on-farm implementation of a multidimensional sustainability assessment and benchmarking tool for pig and broiler production **280**
L. Mertens, T. Van Daele, A. De Grande, E. Kowalski, E. Delezie, M. Aluwé

One Welfare : Perception and expectation by French representative of beef and dairy cattle sector **281**
L. Mirabito, C. Coghetto, E. Delanoue

One Welfare on a Family Beef Farm: Human–Animal Co-Agency Driving Environmental Adaptation and Relational Innovation **282**
X. Boivin, M. Larue, P. Spoljar, E. Delanoue, B. Mounaix, C. Couzy, G. Barbier, R. Lardy, L. Mirabito

How to balance three welfare dimensions in dairy farm management **283**
A. Kuipers, E. Koloszyck, M. Klopcic

Balancing three pillars of welfare to maintain a promising future for dairy farming in the USA **284**
A. De Vries

Integrating Animal Welfare into Sustainability Assessment of Livestock Systems: A Scoping Review and Expert Consultation **285**
D. Sun, L. Smith, M. Almeida, E. Merlot, M. Gagaoua, I. Rivelli, D. Yanez-Ruiz, S. De Ponti, R. Mcguire, D. Kenny, M. Vilain Rørvang

Interrelationships between animal welfare and sustainability of on-farm best practices for poultry production **286**
M. Perard, E. Caumette, G. Aubin-Houzelstein, A. Trocino, J. Nowak, J. Pawłowska, M. Ocepek, A. Jonassen, A. Collin, L. Elmersson

Rational and Sustainable Rabbit Farming in Burkina Faso for Food Security and Income Creation for Vulnerable Populations: The SOAMBA project **287**
L. Nompleggio, S. Giovannini, L. Bosa, A. Dal Bosco, S. Mattioli, C. Castellini

Poster Session 9

Farmers' Negative Emotions as a Component of the Administrative Burden of Farm Supervision **288**
T. Simonen-Jokinen

Animal welfare and sustainability of pasture-based dairy production: a Life Cycle Assessment modelling approach **289**
M. Dos Santos Lima, L. Torricella, L. Annetti, G. Vignola, A. Collin,, M. Podaliri Vulpiani

Session 10. Positive welfare indicators

Date: Monday 7 September 2026; 8:30 - 12:30
Chair(s): Morgan, O'Driscoll - Commission(s): HW, SG, PO, P, C - Session Type: Theme session

Theatre Session 10

From preventing suffering to measuring positive welfare: Can biological markers reflect Animals' lifetime experiences? **290**
L. Morgan

Wool Cortisol Reveals Cumulative Welfare and Physiological Resilience in Sheep Production Systems **291**
S. Ocak Yetişgin, U. Sen, H. Onder

Telomere Length as a Genomic Biomarker of Environmental Stress in Dairy Goats **292**
F. Sarubbi, R. Tudisco, A. Gallo, A. Siciliano, G. Cappelli, J. L. D'Auria, R. Pistucci, F. Infascelli, P. Iommelli, A. Iannuzzi

Mapping Sleep Architecture in Nellore Beef Cattle: Validation of a Custom Polysomnography System **293**
D. H. M. Watanabe, F. F. Alves, P. H. F. Torres, M. Lhamon, K. Donohue, B. O'Hara, D. D. Millen

Social touch as a positive welfare phenotype in livestock: a cross-disciplinary synthesis of sensory and behavioral evidence **294**
C. Winters

Benefits of temporary access to enriched environments for finisher pigs **295**
M. Cupido, L. Boyle, S. Mullan, K. O'Driscoll

Damaging and play behaviours linked to brain neurochemicals in pigs **296**
G. Troupakis, I. Minussi, W. J. J. Gerrits, A. J. M. Jansman, M. Diepeveen-De Bruin, Y. Vermeiren, J. E. Bolhuis

Group and individual patterns in calf activity during a play arena test **297**
J. D. Bus, M. A. Mason, M. B. Jensen

Herd lying concordance: a novel measure of resting coherence in dairy cows **298**
G. Franchi, D. W. Olijhoek, L. K. Hilligsøe, N. P. Hansen, E. M. V. Hvas, E. H. Jensen, M. Larsen, L. J. Pedersen, M. B. Jensen

Effect of a two-hour daily exit on milk quality, activities and outside behavior of Italian Simmental lactating cows **299**
S. Arango, L. Bailoni, N. Guzzo, S. Currò, E. Bianco, E. Simonetti, S. Rainis, C. Sartori

Technologies for on-farm measurement of positive animal welfare: A scoping review **300**
G. Batikas, J. Y. Chou, M. Battini, N. Blackie, M. Coutant, N. Esenbuga, B. Foris, L. Frondelius, R. Guatteo, A. M. Gutiérrez, M. A. Karatzia, R. Kaura, H. L. Ko, V. Ribikauskas, P. Seddaiu, D. Sun, N. Vázquez, R. Yildiz, O. Schmitt

Poster Session 10

Identifying animal-based indicators for positive animal welfare in laying hens **301**
M. Booijen, F. Hoorweg, M. Wolthuis-Fillerup, M. Van Der Sluis, J. E. Doornweerd, T. Johansson, A. Van Dolderen

Sacred Care and Scientific Compassion: Integrating Positive Animal Welfare into Lifelong Management Systems of Indian Gaushalas **302**
M. A. Karatzia

Effect of enrichment provision and pair-housing on the development of calf locomotor play during the pre-weaning period **303**
M. A. Mason, J. D. Bus, M. B. Jensen

Session 11. Insects and other alternative raw materials as feed for livestock animals

Date: Monday 7 September 2026; 8:30 - 11:45
Chair(s): Renna, Sibinga, Biasato, Schiavone - Commission(s): I, N - Session Type: Theme session

Theatre Session 11

Black soldier fly larvae in poultry feed: nutrition, functionality, and challenges for sustainable production in a circular economy **304**
G. Daş, S. M. M. Seyedalmoosavi, L. Syahrulawal, M. Mielenz, B. Kuhla, J. Zentek, C. C. Metges

Dietary inclusion of Hermetia illucens oil in dairy cows: effects on rumen microbiota and fermentation parameters **305**
L. Rastello, S. Colombini, I. Ferrocino, X. Dai, P. Toral, M. Battelli, M. Coppa, L. Gasco, M. Gerbelle, L. Vernetti-Prot, A. Galli, C. Trespeuch, M. Renna

Black soldier fly larvae (Hermetia illucens) fat as an alternative fat source to coconut fat in milk replacer for calves **306**
N. S. Stöhr, M. H. Ghaffari, J. Hayer, T. Scheu, R. Schemmer, T. Priesmann, C. Koch, G. Dusel

Influence of chitinase inclusion level and application method on the digestibility and utilization of black soldier fly meal in juvenile rainbow trout **307**
S. Bellezza Oddon, A. A. Melis, I. Biasato, K. Loufi, Z. Loiotine, M. Van Spankeren, L. De Jong, L. Gasco

Black soldier fly larvae (Hermetia illucens) meal as an alternative protein source in organic free-range laying hen production **308**
N. S. Stöhr, J. G. Brettschneider, L. Schneider, R. Jha, G. Dusel

Effects of three feeding strategies based on black soldier fly larvae on gut health and redox status in fast-growing chickens **309**
C. Paës, A. E. Abdel-Moneim, L. A. Guilloteau, F. Kempf, C. Gérard, S. Abousaid, V. Tondereau, V. Bezirard, H. Eutamène, E. Baéza, C. Trespeuch, P. Belloir, B. Méda

Does gut health have a key role in shaping growth performance in insect-fed broilers? **310**
I. Biasato, T. Hassan, D. Buzzanca, S. Bagatella, A. Schiavone, M. T. Capucchio, L. Gasco, A. Kenez, I. Ferrocino

Effect of black soldier fly larvae oil and feed withdrawal on meat quality parameters in broilers subjected to cyclic heat stress during the final growth period **311**
M. K. Atehortua, A. J. Maldonado, F. Sevillano, A. I. Rey, M. A. Ibañez, D. Menoyo

Beyond soybean meal: alternative grain legumes in diets for broiler chickens **312**
F. Bordignon, M. Pravato, M. Molin, G. Zorzi, C. Maucieri, G. Xiccato, V. Giannini, A. Trocino

Poster Session 11

Programmable automated dispenser for high-frequency delivery of dried black soldier fly larvae as behavioural enrichment in broilers **313**
F. Sammo, M. Seehaus, C. Manteuffel, G. Daş, J. Langbein

Italian consumers' concerns about the use of insect-derived products in ruminant feed: evidence from CUB models **314**
G. Mastromonaco, V. M. Merlino, L. Rastello, L. Gasco, S. Massaglia, M. Renna

Protein-rich, locally sourced feed ingredients efficiently utilized by young chicks **315**
M. Traineau, J. Danel, I. De La Borde, P. Carre, M. Vilarino

Impact of BSF Larvae Inclusion on Pig Growth **316**
A. C. G. Monteiro, T. Mariano, R. Pereira, R. Fortunato, D. Murta, V. Pinheiro, D. Monteiro

Effects of Replacing Plasma Meal with Defatted Black Soldier Fly (Hermetia illucens) Larva Meal on Post-Weaning Piglet Performance, Blood Parameters, and Histopathology **317**
M. Parreiras, V. Pinheiro, O. Moreira, D. Monteiro

Session 12. Digital Innovations for Welfare and health focused Livestock Management - Part 1

Date: Monday 7 September 2026; 8:30 - 12:00
Chair(s): Díaz de Otálora, Foris, Gautier, da Silva - Commission(s): PLF, HW - Session Type: Theme session

Theatre Session 12

Recovering missing calving events to improve lactation number accuracy in commercial dairy cow datasets **318**
A. Edvardsson Rasmussen, I. Ohlsson, T. Klingström

Toward a digital model of dairy cow time budget and related energy expenditure **319**
M. Danglot, O. Martin, M. Valenchon, C. Largouët, C. Gaillard

Digital Transformation in Animal Assessment: A Mobile Application for Real-Time Data Collection and On-Site Analysis **320**
M. Volk, L. Jung, D. Hinrichs

Human classification of pig vocalizations shows limited context-independent emotional structure **321**
C. Winters, B. Sleurs, W. Gorssen

Low cost IoT system for monitoring environmental conditions and behavior in pig production **322**
J. A. Osorio Saraz, V. Gonzalez Cadavid, F. A. Obando Vega, E. Herrera Pasos, A. M. Diaz Lopera

Added value of multi-sensor behavioural monitoring in infectious disease trials: a case study with pigs challenged with African Swine Fever Virus **323**
H. P. Doekes, B. Han, N. Oreshkova, R. De Jong

Application of Multimodal IMU Metrics to the Behavioral Assessment of Pigs **324**
D. Foy, T. Smith, J. Reynolds, T. Parsons

Development of an Automated Posture Prediction System for Sows Using Artificial Intelligence **325**
T. Cochou, N. Barry, J. F. Bompa, W. Hébrard, S. Ferchaud, G. Delosières, M. Aletru, L. Canario, M. Bonneau

Automated computer vision analysis of pig appeasing pheromone effects on social behaviour and welfare in group-housed sows **326**
N. Ipek, J. Verwaeren, B. De Baets, F. Tuyttens

Camera-based computer vision monitoring of pig behaviour under heat stress **327**
N. Hlel, D. A. Mendez, X. Díaz De Otálora, F. Estellés, S. Calvet, D. Liu, T. Norton

Zero-shot computer vision-based analysis of social behaviour among group-housed sows **328**
N. Ipek, J. Verwaeren, B. De Baets, F. Tuyttens

Moo4feed R package: Decoding individual animal narratives through precision livestock monitoring data **329**
K. Sheng, B. Foris, D. Weary, M. Von Keyserlingk

Poster Session 12

Influence of incomplete milking on the oxidative stress status in dairy cows during peak to mid lactation **330**
K. M. Flüchten, P. M. Von Trotha, R. Joest, B. Heitkönig, C. Heinemann, U. Müller

Automatic detection of cattle vocalizations based on spectrogram correlation, eigensounds, and deep learning embedding approaches **331**
D. Gavojdian, L. S. Dragne, M. Mincu-Iorga, A. C. Olteanu

Gender-Related Differences in Growth Performance, Carcass Traits and Blood Parameters of Finishing Pigs **332**
J. Paié-Ribeiro, D. Outor-Monteiro, V. Pinheiro

Automated Monitoring of Rabbit Activity Using Computer Vision: A Comparison of Gaussian, SAM3, and YOLO Algorithms **333**
T. Monreal Fernandez, B. Fajardo Viloria, E. Gil Vidal, F. Marco, S. Calvet, D. A. Méndez Reyes

Can piglets self-regulate their intake when offered two contrasting diets differing in protein and energy? **334**
M. Traineau, J. Danel, M. Vilarino

Effects of incomplete milking during summer on metabolic and oxidative status in peak-lactation dairy cows: a pilot study **335**
R. Joest, M. Ghaffari, T. Hartinger, U. Müller

Hoof Temperature Differences in Relation to Lameness Score **336**
T. Bobić, N. Raguž, M. Oroz, M. Oroz, Ž. Radišić, P. Mijić, B. Lukić

Improving Real-Time Sow and Piglet Behavior Detection Using Mixed-ELAN Architecture **337**
Y. H. Choi, H. J. Kim, C. B. Lim, H. J. Park, J. E. Kim, Y. J. Min, Y. D. Jeong, H. Jung

AI-Based Early Warning System for Tail Biting Risk Detection suitable for Diverse Pig Husbandry Systems **338**
K. Shehzad, D. S. Küster, D. S. Diers, P. D. .. H. J. M. Gómez, P. D. I. Traulsen

Session 13. Challenges to Mineral Balance and Intermediary Metabolism

Date: Monday 7 September 2026; 8:30 - 12:15
Chair(s): Wilkens, Koch - Commission(s): PH, N - Session Type: Theme session

Theatre Session 13

Dietary Phosphorus Restriction Alters IGF Availability Independent of Hepatic GHR Signalling in Young Goats 339
K. Wittenberg, K. Hustedt, N. Schnepel, A. Hoeflich, A. S. Muscher-Banse

Maternal methionine supplementation in low-protein diets during late gestation and lactation increases the performance and alters fecal microbiota of the sows and their offspring 340
Y. Duan, M. Wan, Y. Yin

Comparison between copper sources and benzoic acid supplementation in weaned piglets 341
Y. J. Manaig, L. Blavi, A. Rigo Monteiro, S. Durosoy, S. Tibble, F. Gonzalez

Effect of trace mineral source on copper, manganese, and zinc concentrations in ruminal content and feces of crossbred steers in grazing conditions 342
F. P. Leonel, D. Brito De Araujo, K. V. Z. Augusto, M. E. L. Rezende, T. Engle

Calcium, bone and energy metabolism of dairy goats supplemented with poplar leaves during early lactation 343
K. Helffenstein, M. R. Wilkens, B. Kuhla

Discovering the plasma metabolic fingerprint of heat-stressed Holstein dairy cows 344
F. Koch, D. Rico, R. Mandal, B. Kuhla

Proteome characterization of milk extracellular vesicles isolated from cows during heat stress 345
Y. Dadi, M. Delosiere, L. De Matos, A. Delavaud, M. Penati, D. Viala, G. Salvi, O. Balbi, A. Imbert, P. De Palo, A. Maggiolino, F. Ceciliani, M. Bonnet, C. Lecchi

Heat stress induced alterations in the hepatic lipid metabolism in primiparous dairy cows 346
S. M. Sarkar, D. Dannenberger, D. Rico, B. Kuhla, F. Koch

Predicting subclinical ketosis in Holstein dairy cows using fatty acid content in milk 347
A. R. Sharifi, M. Zschiesche, N. Gengler, J. Hummel, H. Jansen

Can milk fatty acid profile serve as a predictor of different types of hyperketolactia in dairy cows? 348
J. Kwaśniewska, W. Młocek, K. Słoniewski, R. J. Van Saun, Z. M. Kowalski

Associations between hyperketonaemia, glucose and phosphate 349
M. O. Matthäi, G. Köller, S. U. Kononov, J. Rehage, L. H. Baumgard, M. R. Wilkens

The association of postpartum inflammatory-metabolic status with early-lactation milk yield in clinically healthy cows 350
N. Taechachokevivat, L. M. Avila-Granados, J. Grantz, A. Ueda, R. Neves

Poster Session 13

Effect of phosphate source on phosphorus digestibility in cows 351
C. Omphalius, A. Bonnel, C. Gousset, B. Ribeiro, S. Julliand

Changes in rumen fermentation pattern with additional dietary potassium supply 352
Y. Zhang, H. Han, J. Guyader, S. Li

The effects of total dietary copper, sulfur, molybdenum, and Cu:Mo ratio on Cu status of sheep: A meta-analysis **353**
J. A. Johnson, J. L. Ellis, G. B. Penner

Influence of copper source on hepatic Cu accumulation, redox status and bile acid profiles in weanling and growing pigs **354**
S. Cros, M. Fornòs, A. Monteiro, I. R. Ipharraguerre, G. Rimbach, H. H. Stein, J. F. Perez, D. Solà

Session 14. Utilization of automatically recorded traits (sensor data) in cattle breeding and production

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Egger-Danner, Cesarani - Commission(s): G, PLF - Session Type: Theme session

Theatre Session 14

Genetics of traits derived from measures of milk electrical conductivity collected by milking robots and their correlations with clinical mastitis in Holstein cattle **355**
J. M. Maskal, S. Y. Chen, L. F. Brito

Personality-informed genomic prediction of sensor-derived feeding behaviour and resilience traits in dairy cows **356**
A. Seidel, P. Hasenpusch, T. Wilder, G. Thaller

Genetic parameters of rumination and eating behaviour in Holstein cows monitored using collar-based precision livestock farming sensors **357**
V. Brajkovic, M. Oroz, M. Oroz, N. Raguz, I. Drzaic, M. Shihabi, M. Špehar, T. Bobic, I. Curik, B. Lukic

Big Data Meets Behavior: Genetic Characterization of AMS-Based Indicators in Dairy Cows **358**
J. Stuhlträger, F. Rosner, S. König, L. Behren, L. Breitmeier, H. H. Swalve

Genetic parameters of feeder replacement traits from electronic feeders' records in cattle **359**
J. D. P. S. Valente, L. F. M. Mota, G. R. D. Rodrigues, T. L. S. Soares, J. A. Silva, K. D. S. Pinto, L. F. C. Araujo, R. C. Canesin, S. F. M. Bonilha, J. N. S. G. Cyrillo, M. E. Z. Mercadante

Relationship between daily milking records and health status of dairy cows **360**
E. Kašná, L. Zavadilová, Z. Krupová

ICAR/IDF Sensor Initiative: Guidelines and reference standards for using rumination sensor data in animal health and welfare - recommendations for sensor data use for genetic evaluation **361**
C. Eggerdanner, I. Klaas, L. Brito, J. Bewley, V. Cabrera, S. Dagan, R. Fourdraine, N. Gengler, M. Haskell, B . Heringstad, M. Hostens, M. Iwersen, F. Karlsson, G. Katz, M. Moleman, M. Phelan, E. Rossi, K. Schodl, D. Sieben, K. Stock, A. Stygar, E. Vasseur

Three-dimensional imaging provides scalable body weight phenotypes for management and breeding in dairy cattle **362**
C. Bengtsson, K. Kupisiewicz, R. Bak Stephansen, J. Lassen

Grazing traceability of dairy cows with GPS and accelerometer sensors. **363**
C. Allain, A. Delpeuch, M. Vimont, M. Legris

Effect of eating dynamics on enteric gas concentration recorded via sniffer in dairy cows **364**
G. Giagnoni, M. Bjerring, V. Milkevych, T. M. Villumsen

Non-invasive infrared measurement of exhaled methane in dairy cows based on spot sampling during automatic milking **365**
F. Neubert, A. M. Scholz, A. K. Calliotte, C. Schmidt, P. V. Kremer-Rücker

Broader potential applications of sniffer systems: A pilot study of installation on automatic feeder station 366
C. Rossi, G. Grossi, N. Lacetera, A. Vitali

Proxies for early lactation ketosis in Austrian Fleckvieh dairy cattle based on daily milk yield and rumination data 367
K. Schodl, B. Fuerst-Waltl, F. Steininger, C. Egger-Danner

Poster Session 14

AI-based 3D monitoring of behavior and welfare indicators in cows during the preclinical phase of atypical BSE 368
S. Jahn, S. Ernst, C. Fast, T. Homeier-Bachmann

Sniffing the sustainable dairy future: experiences establishing methane emissions monitoring in Swedish dairy herds 369
I. Ohlsson, I. Clegg, E. Lövbom, E. Rius-Vilarrasa, P. Ask-Gullstrand, S. Nyman, A. Medved, B. Gustafsson, L. Bark, M. Bjerring, T. Villumsen, T. Klingström

Session 15. Safeguarding the Future: The Role of Livestock Diversity in Sustainable Agriculture

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Berg, Mészáros, Lino Neto Pereira - Commission(s): G - Session Type: Theme session

Theatre Session 15

Combining population and quantitative genetics to improve genomic prediction 370
E. Tourrette, G. Hélène, B. Servin

Breeding Perspectives on Red and White Dual-Purpose Cattle: Results from a Multinational Survey 371
M. Albers, F. Schmidt, Y. Huppertz, N. Gengler, D. Hinrichs, G. Thaller, N. Krattenmacher

Impact of relationship matrices on inbreeding control in pig populations under optimum contribution selection 372
K. Kelles, N. Leite, M. Van Son, Y. Wientjes, E. Hanenberg, E. Grindflek, P. Berg, T. Meuwissen

Performance of optimal contribution selection depends on the accuracy of selection candidates 373
J. R. Thomasen, H. M. Nielsen, M. Kargo, S. Tenhunen, H. Liu

Surveying and evaluating UK farm animal genetic diversity estimates 374
C. M. Rochus, C. F. Price, I. Pocrnić

A genomic survey of the Romagnola beef cattle breed 375
D. Colombi, F. Sbarra, F. Perini, A. Quaglia, E. Lasagna

Seven decades in liquid nitrogen: Viability and fertility of historic bovine semen 376
R. Herbicht, K. Jilek, C. Klein, H. Henning

Genomic diversity and population structure in Nordic Red Dairy Cattle populations 377
S. Tenhunen, L. P. Sørensen, A. Gjuvsland, J. R. Thomasen, M. Kargo, P. Uimari

Global Variability of the Chicken D-Gene Region 378
J. Geibel, M. Brunner, A. Weigend, C. Reimer, T. V. L. Berghof, S. Weigend, B. Schusser

Genomic consequences of a historical bottleneck after demographic recovery in the Old Norse sheep 379
C. Brekke, P. Berg

Native African cattle as important genetic resource for environmental adaptation 380
J. Friedrich, S. Kambal, N. A. Adossa, A. M. Ahbara, M. T. Makumbe, O. Matika, J. M. Mwacharo, K. Bougiouri, F. Racimo, O. Hanotte, P. Wiener

Comparison of genomic vs pedigree-based inbreeding in the Italian Simmental cattle breed 381
N. Macciotta, L. Degano, D. Vicario, C. Dimauro, A. Cesarani

Poster Session 15

Detection of homozygosity and heterozygosity rich regions on German Black-Headed Mutton x Kıvırcık (Bandırma) sheep population 382
S. Koncagül, A. Özdemir, A. Kasakolu

Associations between individual-specific genetic correlations and gametic variability 383
S. Chalhoub, P. Croiseau, P. Martin, D. Boichard, B. Cuyabano

Analysis of β-casein and β-lactoglobulin variant frequencies in Podolica beef cattle 384
D. Colombi, F. Sbarra, F. Perini, G. Pedota, A. Quaglia, E. Lasagna

Genetic diversity and effective population size in the Belgian Landrace pig: insights from SNP genotypes and pedigrees 385
S. Guan, R. Meyermans, W. Gorssen, K. Hooyberghs, L. Chapard, N. Buys, S. Janssens

Phenotypic data to assess the resilience potential of Sicilian cattle breeds in the context of climate change 386
A. Antoci, S. Tumino, M. Carlentini, G. Chessari, A. Criscione, S. Bordonaro, D. Marletta

Challenges for the Conservation of Farm Animal Genetic Resources under Emerging Animal Diseases 387
E. Sosin, A. Chełmińska

Session 16. European resilient livestock farming systems in a continuously changing world. Part 2

Date: Monday 7 September 2026; 14:15 - 17:45
Chair(s): Sturaro, De Magalhaes, Hadjipavlou - Commission(s): LFS, SG - Session Type: Discovery session

Theatre Session 16

From concept to measurement: Advancing resilience analysis in small ruminant farming systems 388
D. Martin-Collado, A. Bernués, M. Y. R. Couto, A. Prat-Banhamou

Using extended lactations to shape resilience of goat farming systems: a modelling approach 389
C. Descheerder, O. Martin, F. Bidan, C. Duvaux-Ponter, L. Puillet

The Aegean sheep breed revisited: Phenotypic description and husbandry characteristics in island flocks of Greece 390
M. Karatzia, I. Bouzalas, T. Papadopoulos, E. Kanaki, A. Lymperopoulos, T. Vanikiotis, I. Chaligiannis, L. Ekateriniadou

Role of territorial stakeholders in the management of risks arising from interactions between wildlife and pastoral livestock systems **391**
I. Mokrani, M. Ockman, C. Bellanger, M. Ben Abdellah, L. Chaland, H. Debay, H. Faber, C. Gauvrit, E. Ruelle, A. Vedrine, M. Virapin

Drivers of abandonment risk in autochthonous livestock systems: preliminary results from Castilla-La Mancha. **392**
J. Claros-Zafra, J. M. Perea, M. A. Cantarero-Aparicio, R. Arias, J. M. Gallardo, E. Angón

Resilience of European Livestock Systems: multi-scale, context-specificity and methodological insights **393**
F. Accatino

INOSYS "farm models": a national living lab to simulate change and explore adaptation pathways in French livestock systems **394**
G. Mathieu, D. Sterling

Intensive holm oak plantations as a climate adaptation strategy to enhance resilience of traditional Iberian pig production systems **395**
J. García-Gudiño, A. Ortiz, M. Freire, J. M. Pérez-Rodríguez, A. I. Del Rosario, L. León, D. Tejerina

Multidimensional information system for zootechnics: the case study of buffalo farm and the dark side of outsourcing drivers **396**
D. Vecchio, M. Serrapica, G. Di Vuolo, G. Cappelli, V. Lorenzi, C. D. Ambra, F. Serrapica, A. Vastolo, G . Rofrano, L. J. D'Auria, A. Atzori, G. Stilwell, L. A. De La Cruz Cruz, A. Zanella, M. Giampietro, A. Fierro

Supply chain vulnerability in protein reduced poultry nutrition: A scenario approach to amino acid supply disruption in broiler production **397**
J. Gickel, C. Visscher

Session 17. Beef on Dairy (I): Improving husbandry conditions of dairy beef calves both at the dairy and the fattening farms to gain better societal acceptance

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Hammon, Bachmann - Commission(s): C - Session Type: Theme session

Theatre Session 17

Building a resilient dairy-beef calf: Integrating genetics, early-life management, and producer decision-making **398**
D. Renaud

Early group housing of female dairy calves: first results of the COLOCAVO project **399**
D. Fouvez, G. Trou, C. Roy, L. Oble, F. Lepeltier, V. Lollivier, F. Crepel, M. Le Guenic, M. Vimont, C. Hardy, L. Mirabito

Is increasing pellet diameter an effective strategy to achieve the withdrawal of straw (forage) in the fattening of crossbred dairy beef calves under straw (forage) scarcity? **400**
L. Llonch, S. Marti, A. Solé, J. Riera, C. Medinyà, J. Cucurull, M. Devant

Grass-based or maize-based TMR for young bulls have similar effects on growth and carcass quality but different effects on health **401**
M. Vestergaard, M. L. Petersen, A. M. H. Kjeldsen, N. B. Kristensen

Reduction of stocking density during the transport of finishing dairy beef calves to the slaughterhouse: truck thermal microclimate and calves' stress indicators 402
A. Martín, N. Naranjo, M. Devant, M. Herskin, Z. Chen, T. Norton, S. Martí

Transport of unweaned calves: risk factors and future perspectives 403
S. Marti, F. Marcato

Comparison of organ development at arrival in transported dairy beef calves from two origins: multi origin marketed calves and calves sourced directly from proximity dairy farm 404
C. J. García Vázquez, M. Devant, S. Marti

Nutritional strategy combining sensory additives and olive bioactives enhances post-transport recovery of dairy beef calves with pneumonia 405
A. Martín, M. Blanch, M. Devant, S. Martí

An overview of dairy-calf systems for meat production in north-west Europe 406
P. Crosson, B. Berthelot, P. Madrange, A. Mertens, C. Battheu-Noirfalise, E. Henrotte, R. Reading, R. Riedel, F. Kaemena, I. Morel

Who Is Willing to Compromise? Consumer Clusters, Societal Acceptance of Alternative Housing Systems and Trade-Offs in German Beef Cattle Production 407
F. Von Steimker, E. Bayer, S. Kühl

Poster Session 17

Comparison of two rearing methods for calves: Effects on weight gain and health during the first four weeks of life 408
B. Meijer, J. Kleist, L. Bachmann

Effects of weaning protocols on feed intake and growth performance in calves fed milk replacer ad libitum until 7 weeks of age 409
A. Stoschus, L. E. Diesing, T. Nieschulze, K. Braun, W. Liermann, H. M. Hammon

Changes of metabolic traits in blood of dairy calves after ad libitum milk feeding using different weaning protocols 410
L. E. Diesing, A. Stoschus, T. Nieschulze, K. Braun, W. Liermann, H. M. Hammon

Effect of weaning duration (3 vs. 6 weeks) on plasma acylcarnitine and free fatty acid profiles in ad libitum–fed dairy calves 411
M. Hosseini Ghaffari, A. Stoschus, L. E. Diesing, S. Schuchardt, H. M. Hammon

Prevalence of ESBL/AmpC-E. coli before and after the implementation of specific intervention measures in two dairy farms 412
J. F. Kleist, C. Silhavy, T. Homeier-Bachmann, L. Bachmann

Lung scanning at arrival of calves in veal calf herds 413
H. L. Martin, A. M. Kjeldsen

Normal or low iron level in milk replacers for 1 to 2 months old dairy-beef calves 414
C. B. S. Geven, N. B. Kristensen, H. L. Martin, M. L. Petersen, M. Vestergaard

Alternative forage sources to wheat straw in crossbred dairy beef calves fed high-concentrate diets 415
L. Llonch, S. Marti, A. Solé, N. Naranjo, Á. Serrano, J. Riera, C. Medinyà, J. Cucurull, M. Devant

Performance and Meat Quality of German Holstein Steers in a Silvopastoral System 416
T. Krebs, A. Boldt, R. Wulf, S. Maak, K. Barth

Evaluating short and long colostrum replacer protocols to support recovery in dairy beef calves after transportation 417
C. J. García Vázquez, M. Verdu, J. Cucurull, X. Soldevila, M. Devant, S. Marti

Evaluation of the effect of social housing practices for replacement and fattening calves from birth to transport and later stages of life 418
J. J. Hayer, A. Peine, C. Göckeritz, K. Bauch, P. Berghuis, S. Schäfer, P. Schneider, D. Frieten, I. Steinhöffel

Comparative effects of two sensory feed additives on recovery and adaptation of commercially transported unweaned dairy beef calves from arrival to post-weaning 419
J. J. Narváez, N. Llanes, M. Blanch

Spanish consumer preferences for meat credence signals in beef and lamb: evidence from a mixed logit model 420
M. A. Cantarero-Aparicio, E. Angón, J. Claros-Zafra, M. Luque-Cuesta, J. M. Perea

Better-Calf: Dairy calf systems for resilience, welfare and sustainability in rural territories 421
P. Crosson, B. Berthelot, A. Mertens, C. Battheu-Noirfalise, E. Henrotte, R. Reading, R. Riedel, F. Kaemena, I. Morel, P. Madrange

Session 18. Circular/Sustainable feeds in the supply chain: alternative feed ingredients - Part 2

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Ranilla García, Ottoboni, Foggi - Commission(s): N - Session Type: Theme session

Theatre Session 18

Fresh vs. ensiled Rose (Rosa rugosa Thunb.) pomace: effects on rumen methane production and fatty acid biohydrogenation in vitro 422
S. Olorunlowu, P. Sidoruk, J. Sznajder, J. Szczesny, B. Ola, S. Ślusarczyk, A. Cieslak

Effect of a combination of hazelnut and cocoa bean by-products on in vitro ruminal fermentation and biohydrogenation 423
R. Senatore, M. Coppa, C. Baila, G. Hervás, P. Cornale, P. Frutos, P. G. Toral

Effect of carrot inclusion level on the in vitro fermentation kinetics of dairy sheep diets 424
C. Saro, A. Díaz, I. Mateos, N. Merino, S. López, M. J. Ranilla

Rumen degradability, fermentation dynamics, and methane production of potato co-products using in vitro batch culture and rumen simulation technique 425
M. Hassan, C. Christodoulou, S. Ormston, K. E. Kliem, P. Kirton, N. Coetzee, R. Pilgrim, D. R. Yañez-Ruiz, A. Belanche, L. G. Smith, N. Davison, S. Stergiadis

Can corn in a dairy sheep ration can be replaced with cull carrots? 426
N. Merino, J. Giráldez, A. Díaz, C. Saro, I. Mateos, J. Mateo, I. Caro, M. J. Ranilla

Valorization of agro-industrial by-products: effects of brewery spent grains and olive leaves on milk quality and sustainability indicators in grazing ewes 427
V. Bolletta, M. Pauselli, E. Lilli, M. Vispi, B. Valenti

Sesame Seed Meal as a Local Alternative Protein Source in Lamb Diets: Effects on Animal Performance and Meat Quality 428
A. Natalello, M. S. Cannone, M. Musati, S. Privitera, F. Mangano, A. Bertino, M. Lanza, G. Luciano, L. Biondi, A. Priolo, G. Mangione

Replacing soybean products with dried brewer's grains and sunflower meal in light lambs' diets: implications on meat quality and fatty acid profile. 429
J. L. Lema-Hurtado, J. M. Arroyo, T. De Evan, A. Recalde, J. Mateo, M. Dehnavi, M. D. Carro

Long-term impact of avocado seed (Persea Americana L.) inclusion during early-life on ruminal fermentation, blood parameters, fertility and milk yield performance in Murciano-Granadina goats 430
A. Sánchez-García, M. Romero-Huelva, D. Yáñez-Ruíz, A. I. Martín-García

Adapting Dairy Cow Diets Toward a More Resilient and Efficient System by Using Sorghum Silage 431
M. M. Shaklouf, N. Prat, M. Terré

Wheat Silage and Hempseed Cake as Sustainable Alternatives in the Feeding of Dairy Cows 432
A. Latrofa, N. Guzzo, S. Currò, N. Amalfitano, J. Bisello, S. Arango, C. Sartori, A. Simonetto, L. Bailoni

Improving the nutritional value of canola, flax, and wheat straw to beef cattle with calcium hydroxide treatment 433
C. Ross, G. Ribeiro, G. Penner

From waste to worth: Chemical, physical and functional properties of spent mushroom substrates with implications for ruminant nutrition 434
R. Khiaosa-Ard, L. Spoljaric

Poster Session 18

Exploring the use of fresh apples in dairy cow diets 435
M. Terré, N. Prat, D. Sabrià, J. M. Palma-Hidalgo

Implementation of a short-term palatability test to evaluate dairy cows preference for Carinata meal 436
L. Dicks, Y. Roman-Garcia, G. F. Schroeder

Protein value for ruminants of brewer's grains from Spanish breweries 437
J. L. Lema-Hurtado, M. D. Carro, T. De Evan, I. Macarrón, A. Cabezón, A. Recalde, A. Alcamí-Aguado, J. M. Arroyo

Ensiling discarded tomatoes with dried beet pulp, almond hulls or wheat bran: effects on silage quality 438
A. Alcamí-Aguado, J. M. Arroyo, T. De Evan, J. L. Lema-Hurtado, S. Salazar, W. Santos, A. Recalde, F. Bacha, M. D. Carro

In vitro gas production kinetics of different conventional and non-conventional feeds 439
N. Merino, I. Mateos, A. Díaz, C. Saro, S. López, M. J. Ranilla

Assessment of gas production kinetics in dairy sheep diets including bell pepper as an ingredient replacing conventional feedstuffs 440
I. Mateos, N. Merino, A. Díaz, C. Saro, S. López, M. J. Ranilla

Gas production kinetics of dairy sheep diets with increasing amounts of leek 441
A. Díaz, I. Mateos, C. Saro, N. Merino, V. Rodríguez, M. J. Ranilla

Effect of replacing corn with cull carrots in the diet of dairy sheep on milk retinol and tocopherols 442
J. Mateo, M. Valdés, D. Plata, I. Caro, A. Díaz, N. Merino, I. Mateos, F. J. Giráldez, C. Saro, M. J. Ranilla

Chemical composition, fermentative characteristics and microbial quality of wet brewers' grains ensiled with dried citrus pulp or almond hulls 443
A. Alcamí-Aguado, J. M. Arroyo, T. De Evan, A. Recalde, J. L. Lema-Hurtado, C. Fernández, M. D. Carro

Variation in the composition of oil hemp (Cannabis sativa) and camelina (Camelina sativa) seeds **444**
M. Lamminen, A. Halmemies-Beauchet-Filleau, T. Kokkonen

In vitro assessment of Sicilian agro-industrial by-products and derived biochars as potential feed ingredient for animal nutrition **445**
C. Spedale, V. Chiofalo, M. Puglia, S. Pedrazzi, S. Frazzini, L. Rossi, M. Dell'Anno

The NUTRIFEEDS approach: Regenerative feed innovation through fermentation, insect bioconversion and gut ecosystem modulation **446**
J. Zentek, B. Martínez-Vallespín

Rapid NIRS Evaluation of Cereal–Legume Forage Mixtures from Pre-Wilting to Ensiling **447**
S. Currò, A. Latrofa, N. Guzzo, J. Bisello, S. Arango, V. Bondesan, L. Bailoni

Session 19. From nutritional recommendation to feeding practice - Part 2

Date: Monday 7 September 2026; 14:15 - 17:30
Chair(s): Manaig, Alvarez-Rodriguez - Commission(s): N - Session Type: Theme session

Theatre Session 19

Effects of adaptation length to non-roughage finishing diets on intake, performance, and carcass traits of Bos indicus cattle **448**
R. J. Oliveira, P. H. C. Ribeiro, L. M. Machado, E. B. Pereira, D. R. Oliveira, F. F. Alves, P. H. F. Torres, G. F. Virginio Junior, A. F. Toledo, D. D. Millen

Multi-property evaluation of late-gestation protein supplementation to improve reproductive efficiency in dry tropical beef systems **449**
L. Prada E Silva, K. Mccosker, G. Somerset, K. Eyre

Multi-Trait Growth Parameter Estimation in Beef Cattle Using a Bayesian Non-Likelihood Framework **450**
M. M. Suma, M. Shirali, F. Lively, G. Pexas, I. Kyriazakis

Effects of adaptation protocols to non-forage high-energy diets on dry matter intake, rumen pH, and redox potential of cannulated Nellore cattle **451**
B. C. Afonso, B. C. Petean, K. E. Loregian, A. F. Toledo, D. D. Millen

Compositional and Nutritional Differences Among Major Forages in the Po Valley: A One-Year Analysis **452**
M. Ottoboni, P. Premarajan, A. Luciano, M. Manoni, M. Senese, K. Simeonidis, A. Moradei, E. Pacifico, E. Grandi, L. Pinotti

Can entire male pigs be fatter by switching the sire line from Pietrain to Duroc or increasing dietary energy? **453**
N. Quiniou, M. Monziols

Impact of increased dietary phytase levels during gestating sows on offspring performance, bone mineral content and mechanical properties **454**
J. Suppi, E. Llauradó-Calero, M. Fornós, D. Solà-Oriol

Molecular mechanism and nutrition regulation of meat quality traits in Chinese Indigenous Pigs **455**
Y. Duan, Y. Yin

How deviations of requirement feed intake during mid gestation affects sows' body composition **456**
R. Carnevale, S. Millet, N. Nollet, C. Garbossa, A. Cools, G. Janssens

His supplementation increases muscle carnosine concentrations in weaned piglets. 457
A. J. Galindo, D. Solà-Oriol, M. Paniagua

Acorns from intensive holm oak plantations during Montanera finishing phase: impact on the fatty acid and antioxidant profiles of Iberian pig meat 458
A. Ortiz, J. García-Gudiño, M. Freire, L. León, J. M. Pérez-Rodríguez, A. I. Del Rosario, D. Tejerina

Poster Session 19

Effects of Dietary Extruded Flaxseed and Betaine on Haematological and Biochemical Parameters in Finishing Pigs 459
D. Outor-Monteiro, S. Mendes, T. Santos, J. Páie-Ribeiro, V. Pinheiro

Effects of harvest time, dry matter content and additives on fermentation characteristics of grass-clover silage 460
J. Perez, J. Dicksved, M. Presto Åkerfeldt, H. Gonda

Short-term protein-energy restriction in starter diets triggers compensatory growth, increased ghrelin and improved jejunal morphology in weanling pigs 461
M. A. C. George Kalaivanan, S. Cho

Optimizing early and mid-gestation feed allowance improves litter outcomes in sows under summer heat stress 462
J. H. Lee, S. M. Koo, S. N. Jo, J. C. Jang

Effects of Extruded Linseed and Betaine on Growth Performance of Finishing Pigs 463
D. Outor-Monteiro, S. Mendes, T. Santos, J. Páie-Ribeiro, V. Pinheiro

Session 20. How does longevity relate to the welfare of breeding animals?

Date: Monday 7 September 2026; 14:15 - 17:30
Chair(s): Meier, Boyle - Commission(s): C, HW - Session Type: Discovery session

Theatre Session 20

The devil is in the details: Is longevity a good indicator of farm animal welfare? 464
M. A. Von Keyserlingk, S. E. Bolton, K. L. Proudfoot

Genetics meets management: Explaining the gap between genetic and phenotypic trends of longevity in dairy cattle 465
L. Hüneke, G. Thaller, C. Schmidtmann

Investigations on an optimal longevity of dairy cows in practical farms in the North-East of Germany 466
A. Römer, J. Harms, A. Boldt, P. Sanftleben

Mortality and lifetime milk yields of Finnish dairy cows during 2011 - 2020 467
K. Sarjokari, K. Hagner, H. Nordgren, T. Hurme, H. Rautala, P. Rajala-Schultz

Longitudinal evidence that genomic functional longevity reflects biological resilience in Holstein Friesian cows 468
M. Hosseini Ghaffari, N. Melzer, D. Wittenburg, M. Elsabagh, D. Becker, F. Becker, C. Kröger-Koch, H. M. Hammon

Sow longevity: phenotypic time trends, the effect of litter size, and economic values 469
P. Knap, J. Holl, C. Lewis

Long-life sows: how breeding performance tailors longevity in breeding farms **470**
A. Arrazola, R. Quintanilla, N. Alòs, L. Tusell, J. Tarrés

A multi model, multi imputation framework for predicting sow culling risk across parities **471**
M. Sungirai, C. Mulvenna, R. Muns

Session 21. Resilient pigs in resilient farming systems – health, welfare and robustness in practice. How to cope with changing expectations and legislation - Part 2

Date: Monday 7 September 2026; 14:15 - 17:45
Chair(s): Arnaud, Morgan, Aluwé - Commission(s): P, HW - Session Type: Theme session

Theatre Session 21

Extensification is not one-dimensional: contrasting welfare and meat quality responses to space, enrichment and roughage in fattening pigs **472**
M. Coutant, M. S. Hedemann, M. S. Grønbeck, M. Hviid, L. J. Pedersen, M. L. V. Larsen

Straw in, straw out: Do quantity and location of straw affect pig health in welfare label farms? **473**
N. Nöllenburg, C. Winckler, S. Schwarz, C. Leeb

Effects of farrowing in pens or crates on sows and piglets **474**
A. Vernunft, C. Gladbach, H. Lickfett, M. Oster, K. Wimmers

Balancing productivity and welfare to improve resilience in modern pig farming systems **475**
K. O'Driscoll

Castration alternatives in European pig production: Welfare outcomes, technical feasibility and adoption trends **476**
M. Almeida, J. Teixeira, D. Monteiro, V. Pinheiro, S. Silva, V. Courboulay, P. Chevillon

Duration of muscle excitations during inert gas stunning of slaughter pigs: Do they influence meat quality? **477**
J. Gelhausen, I. Wilk, D. Mörlein, J. Tetens, J. Knöll

Longitudinal study: Swine inflammation and necrosis syndrome in suckling piglets is associated with tail length and integrity in slaughter pigs of two organic farms in the Netherlands **478**
K. Koenders - Van Gog, E. Krooshoop, T. Wijnands, M. Lechner, G. Reiner

Status quo of pre-weaning mortality in organic farms in Germany **479**
H. Lickfett, W. Vogt-Kaute, E. Hofinger, M. Kötter-Jürß, G. Schnieders, D. Mai, A. Vernunft

Histopathological characterization of ear damage caused by ear biting and aggression in recently weaned pigs **480**
L. Markland, L. Boyle, F. Leonard, K. O'Driscoll, P. Kelly

Session 22. Novel approaches to addressing the 3Rs and improving the 'culture of care' of animals in the poultry and animal science

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Franchi, Stadnicka - Commission(s): HW, SG, PO, P, C - Session Type: Theme session

Theatre Session 22

Preweaning mortality in laboratory mouse breeding: an animal science and veterinary perspective on a 3R challenge **481**
I. A. S. Olsson, S. Capas Peneda, S. Brajon, C. Gilbert, G. Munhoz Morello

Animal welfare definitions, frameworks, and assessment tools: Advancing the measurement and laying the foundation for improved animal welfare through a three-step approach **482**
F. J. Van Der Staay, V. C. Goerlich, F. L. B. Meijboom, S. S. Arndt

Rethinking animal welfare through the microbiota: early maternal microbial contact builds immune resilience in commercial broilers **483**
H. Zhao, A. De Ceuster, M. Z. Akram, L. Comer, E. Fako, M. Corion, N. Everaert

Ruminant specific multi enzymatic in vitro model accurately predicts in vivo feedstuffs degradability and digestibility to phase out of fistulated reference trials **484**
C. Pineda Vadillo, L. Drouet, C. Favier, C. Vaz Torralba, N. Couvreur, A. Brame, S. Klein

Accurate prediction of apparent metabolizable energy of feedstuffs using a poultry-specific in vitro digestion model **485**
C. Pineda Vadillo, C. Favier, J. F. Faivre, N. Bernard, K. Le Calve, N. Couvreur, S. Klein

Validation of an AI-Based Method for Corneal Endothelial Cell Viability Assessment in an ex vivo Porcine Model **486**
G. Salvi, O. Balbi, M. Penati, L. G. De Matos, A. Zurlo, Y. Dadi, R. I. Lazari, C. Giudice, P. Riccaboni, F. Ceciliani, G. Servalli, F. Gritti, C. Gagliano, L. Ressel, C. Lecchi

Left-side dominance in laying hens: an investigation of chick lateralization following a 10-week exercise regime **487**
R. Garant, B. Tobalske, N. Van Staaveren, D. Powers, T. Widowski, B. Willie, A. Harlander

Implementation of flight-maneuver training in commercial rearing: No extra energy costs **488**
T. Burwell, D. Powers, R. Garant, B. Willie, B. Tobalske, A. Harlander

Isolation of bovine mesenchymal stroma cells from hair follicles as an in vitro model for studies on bovine digital dermatitis **489**
S. Suske, F. Jordan, A. Hornung, F. Rosner, B. Brenig, H. H. Swalve, D. Oelschlägel

In vitro digestion in swine: how close is it to in vivo digestion? – A Systematic Review **490**
M. Pereira, M. Catoia, M. Blanc, I. Bez, L. Costa

Poster Session 22

Development of Ovine Hepatic Organoids: A Powerful In Vitro Platform to Reduce the Number of Experimental Animals Used in Metabolism and Nutrition Assays **491**
S. Andrés, M. C. González-Montero, M. Criado, M. Alonso, N. Santos, D. Gutiérrez-Expósito, F. J. Giráldez, R. Balaña-Fouce, C. García-Estrada

Dynamics of Glutathione Redox Status in Poultry: Impact of Age and Handling Stress **492**
I. Nisamedtinov, K. Hälvin, Y. Le Treut, E. Chevaux, L. Vigier, A. Sacy

Ex vivo cultivation of primary bovine and porcine fat cells to optimize and refine animal tests **493**
Z. Deng, E. Albrecht, H. Gu, C. Xiao, S. Maak

Session 23. Modern approaches in equine breeding: quantitative genetics and selection

Date: Monday 7 September 2026; 14:15 - 17:30
Chair(s): Tan, Mantovani - Commission(s): H - Session Type: Theme session

Theatre Session 23

Targeted sequencing approach for equine microsatellites (Simple Tandem Repeats, STRs) and Single Nucleotide Polymorphisms (SNPs) genotyping to enable transition from STR to SNP-based Equine parentage verification **494**
L. Van De Goor, E. Francis, S. Dam, P. Chemutai, B. Kaufman

Frequencies of known genes of interest in French horses genotyped using a 60K SNP Chip **495**
A. Govignon, B. Dumont Saint Priest, M. Sabbagh, S. Danvy, A. Ricard

Genetic diversity in Dutch horse studbooks based on collaborative pedigree analyses **496**
H. P. Doekes, M. A. Schoon, J. G. C. Van Schipstal, M. J. Steensma, M. F. L. Derks, B. J. Ducro

Genomic inbreeding level of the Coldblooded trotter **497**
P. Berglund, P. Berg, S. Eriksson

Size matters – characterisation of candidate causal variants for withers height in horses **498**
P. Reich, I. Kilic, T. Y. Lin, M. Weis, J. Tetens

Inter- and intra- rater reliability of linear scoring in warmblood breeding **499**
A. Weigt, A. Brockmann, J. Tetens, A. O. Schmitt

Genetics of racing performance across different track conditions in Thoroughbred horses in France **500**
S. Harari, A. Théry, G. Fortier, A. Ricard

Revising selection criteria for endurance performance in Spanish Horses **501**
I. Cervantes, K. D. Arias, N. Formoso-Rafferty, M. Arcos, D. I. Perdomo-González, J. P. Gutiérrez

Early genomic selection for fertility in Pura Raza Española horses using array equigene **502**
H. Srihi, M. Valera, C. Ziadi, N. Laseca, A. Rodríguez Sainz De Los Terreros, P. Azor, I. González, A. Gil-Gálvez, D. Perdomo-González, J. Poyato-Bonilla, A. Encina, S. Demyda-Peyrás, A. Molina

Genomic breeding values for sport performance in German riding horses **503**
M. Wobbe, H. Alkhoder, K. F. Stock

Discipline specialization and its impact on genetic trends followed by genomic breeding values for conformation, gaits and jumping in sport horses in Germany **504**
K. F. Stock, M. Wobbe, C. Schmidtmann

Poster Session 23

Parentage Verification in Pura Raza Española Horses: Transition from Microsatellites to SNP-Based Genotyping Using the EQUIGENE 90K Array **505**
H. Srihi, M. Valera, N. Laseca, A. Rodríguez Sainz De Los Terreros, P. Azor, I. González, A. Gil-Gálvez, J. Poyato-Bonilla, A. Encina, S. Demyda-Peyrás, A. Molina

Population structure and inbreeding in the Old Kladruber horse **506**
B. Hofmanova, H. Vostra Vydrova, L. Vostry

Session 24. Physiological Disturbances on Livestock due to Microplastics and Other Pollutants

Date: Monday 7 September 2026; 14:15 - 17:45
Chair(s): Tretola, Montanholi - Commission(s): PH - Session Type: Theme session

Theatre Session 24

Interactions between microplastics and the gastrointestinal ecosystem of livestock: integrating experimental evidence and emerging concepts **507**
D. Brugger, J. Eichinger

Interaction of polyethylene terephthalate microplastics within the rumen environment **508**
S. Tassone, V. Balestra, S. Barbera, R. Issaoui, H. Kaihara, A. Zanola, K. Abid

Growth, jejunal integrity, and physiology of pigs are maintained with diets containing microplastics **509**
P. Lin, L. Pinotti, G. Bee, M. Tretola

Analysis of microplastics in black soldier fly larvae exposed to packaging materials **510**
L. Tromp, B. Hedemann, N. Dam, N. Meijer

Transcriptomic profiling of aflatoxin B1 exposed and medicinal herb supplemented pig liver **511**
A. A. Nalpadan, H. Reyer, M. Oster, N. Trakooljul, S. Ponsuksili, W. Kozera, K. Karpiesiuk, M. Pierzchała, A. Lepczyński, B. Ślaska, C. S. Pareek, K. Wimmers

Microplastics in animal-based food products: occurrence, contamination pathways, and analytical challenges **512**
E. Visentin, G. Niero, M. De Marchi

LC–MS/MS determination of pesticide and antibiotic residues in milk: effects of thermal processing and composition **513**
M. F. Puigvert, L. Grille, M. Irazoqui, T. López-Pedemonte, S. Jorcín, L. Pareja

Replacement of hexane-defatted oilseed meals with 2-methyloxolane-defatted oilseed meals in dairy cows' diet: Effects on dairy performance and nitrogen utilisation **514**
V. Menoury, A. Ferlay, D. Andueza, G. Cantalapiedra-Hijar, J. Engel, E. Jorge-Smeding, S. Lemosquet, P. Nozière

Voluntary feed intake, body composition and metabolic status differed between growing beef cattle fed hexane vs bio-based solvent-extracted soybean meal in a 7-months feeding trial **515**
E. Jorge-Smeding, C. Garcia-Vazquez, V. Menoury, A. Ferlay, L. Salis, M. Gauthier, P. Faure, P. Nozière, G. Cantalapiedra-Hijar

Determining the impact of anaerobic digestion on the host-range and potential mobility of antimicrobial resistance genes in dairy manure **516**
N. Rahman, A. Z. Rahman, N. Cicek, T. A. Mcallister, H. Derakhshani

Session 25. Digital Innovations for Welfare and health focused Livestock Management - Part 2

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Díaz de Otálora, Foris, Gautier, da Silva - Commission(s): PLF, HW - Session Type: Theme session

Theatre Session 25

Utilizing the shape of the heart to decrease mortality in pig breeding. **517**
Ø. Nordbø, T. Ermens, E. Grindflek

Milking-time indicators link vacuum dynamics, milk flow, and milk quality in Holstein herds **518**
M. Santinello, L. Pascarella, R. Matera, P. Federica, S. Biffani, G. Neglia, R. Negrini

A machine learning framework for early and dynamic prediction of milk, fat, and protein yield of dairy cows **519**
M. Hagens, I. Adriaens, W. Garcia Herrera, A. Marubayashi Hidalgo, M. Sol

Use of Thermography for Monitoring Udder Health Status in Dairy Cows **520**
P. Baronchelli, G. Gislon, M. Zucali, L. Bava, N. Palladini, S. Bonizzi, M. Pavolini, S. Sari, A. Tamburini, M. Battelli, A. Sandrucci

Methods to describe the behavioural resilience of cows after a systemic inflammatory challenge **521**
S. Prins, M. Taghipoor, I. Veissier, F. Blanc, A. De Boyer Des Roches, L. Aube, D. Ledoux

Inferring transmission routes of Staphylococcus aureus using high-resolution contact data in dairy cattle **522**
H. Marina, J. Sanchez, S. Woudstra, I. Hansson, L. Rönnegård

Responses of dairy cow to common stressors: effects on milk production and feeding behaviour traits **523**
M. Braidot, A. Cabbia, E. Florit, M. Corazzin, A. Romanzin

Innovative functional modelling framework reveals black globe temperature as the most robust predictor of circadian heat related behavior in grazing dairy cows **524**
S. Czaplicki, H. Soyeurt, I. Dufrasne

Impact of Weaning and THI on Dairy Calf Behavior **525**
M. Saladini Vieira Salles, M. Benetti Figueiredo, L. Schneider Gheller, M. Martison Martins

Quantification of resilience indicators in broiler chickens through the analysis of growth and feed intake dynamics **526**
Y. Guyot, I. Kyriazakis, M. Taghipoor, V. Jonchère, E. Pampouille, C. Souchet, A. Narcy, B. Méda

Using ultra-wideband tracking technology to monitor activity and area use in broiler breeders **527**
M. Van Der Sluis, R. Van Emous

Correspondence-Based Explainable Deep Learning for Automated Recognition of Pre-Competition Stress in Horses **528**
M. Feighelstein#, L. Teschke#, Y. Solomon, T. Ben Harush, C. Ricci-Bonot, M. Baumgartner, A. Zamansky

Fear reactions in cattle, sheep, and horses to potential predator-deterring stimuli: Does a predator stimulus induce fear-enhanced startle in livestock? **529**
U. König Von Borstel, C. Schnepp, C. Ehry, A. Lauth, K. Trinkaus, S. Lojewski, K. Gondolf

Session 26. Management practices for sustainable poultry (and livestock) systems: welfare, biodiversity, and life cycle perspectives

Date: Monday 7 September 2026; 14:15 - 18:00
Chair(s): Schiavone, Méda, Trocino - Commission(s): PO, P, HW - Session Type: Theme session

Theatre Session 26

How can we effectively improve the welfare of broiler chickens in commercial production systems? A review of farming practices and their relationship with broiler welfare **530**
I. De Jong

Early-life characterisation of temperaments in pullets in relation to subsequent severe feather pecking behaviour **531**
A. Kleiber, C. Boulange, J. P. Moysan, L. Dumontier, L. Calandreau, V. Hugo Bessa Ferreira, A. Foreau, M. Quentin, V. Guesdon, M. Sourdioux, M. Guinebretière

Effects of drinking water optimization on immune, physiological welfare parameters, egg quality, and productivity in laying hens **532**
Y. Wein, M. Subhi, S. Rubin, S. Mabjeesh, I. Yoselevitz, K. Shmuel, A. Friedman

Enhancing laying hen welfare and thermal comfort in cage-free systems using cooled perches. **533**
M. Ross, J. D. Mwifunyi, A. Haron, D. Bachrach, S. Druyan

Welfare indicators during the early rearing period – Comparing young birds of dual-purpose and layer hybrid genotypes under organic conditions **534**
H. Pluschke, D. Werner

Precision farming practices for sustainable poultry production in the USA **535**
L. Chai

A novel method to evaluate the social impact of livestock systems: a social life cycle assessment of the impacts of the Irish pig value chain **536**
C. Wangui, G. Carroll, I. Kyriazakis

Impact of animal welfare on milk production and economic performance in dairy farm **537**
M. Alrhmoun, T. Zanon, M. Gauly

From live animal export to meat and carcass trade: economic, sustainability, and welfare perspective **538**
E. Massalin, S. Blattner, B. Guesmi

Assessment of carcass and meat quality of crossbreeds of local breeds and commercial lines under organic feeding regime containing alfalfa **539**
W. L. Oo, Z. Bodor, M. Krieger, D. Mörlein

The effect of broiler production system on carcass quality **540**
R. Van Emous

Poster Session 26

Genetic characterization of Extremeña Azul, an endangered native Spanish chicken breed, using 30 microsatellites markers **541**
M. R. Maya, L. Borreguero, Á. Trigo, I. Bonet, J. L. Gala Bayón, P. Valera, J. A. Bouzada

Assessing the feasibility of physical enrichments for guinea fowl (Numida meleagris): A combined behavioural and economic analysis **542**
V. Caprarulo, T. Bernardo, S. Gabriele, G. Traversi, S. Carè, V. Lorenzi, L. J. Vinco, L. Bertocchi, F. Fusi

Feather pecking in laying hens: redirected foraging meets a neuroimmune–microbiome gut–brain feedback loop **543**
A. Harlander, A. L. Nicklas, N. Van Staaveren

Keel bone damage of local German chicken breeds and their crosses with high performing laying hens **544**
N. Götzke, A. Weigend, C. Reimer, J. Geibel, A. R. Sharifi, S. Weigend

From performance to footprint: Zootechnical and environmental effects of a protected sodium butyrate supplement in broiler production **545**
B. Saldaña, P. Higuera, C. Landry, M. Panheleux

An innovative plant-based solution that helps prevent the negative effect of coccidiosis **546**
A. Juanchich, J. Dechaume, A. Dupuis, J. Le Douce, M. Brunon, M. Gohin, E. Coudert

Effects of slow-releasing calcium supplementation on growth performance, production performance, egg quality, nutrient digestibility, and blood profile in old laying hens fed a corn–soybean meal diet **547**
J. H. Kim, K. Lee, A. Settuba, K. Han, I. H. Kim

Integrating life cycle assessment into broiler feed formulation: balancing environmental gains, performance, and welfare **548**
J. Lucas, A. Thomas, B. Ruel, E. Barbier

Towards sustainable pig farming in Sardinia: environmental impact and mitigation strategies **549**
M. F. Lunesu, F. Correddu, S. Sechi, S. Carta, S. P. G. Rassu, A. Nudda, G. Pulina, G. Battacone

Same name, same effect? Comparative in vitro repellent activity of Cymbopogon sp. essential oils in blends against poultry red mite **550**
C. Maltret, S. Cisse, M. E. A. Benarbia

Performance stability of local and crossbred chickens under Ascaridia galli infection **551**
A. C. Mott, S. Möller, L. Schwarz, B. Sohnrey, C. Blaschka, E. Zergani, D. Mörlein, S. Weigend, I. Tiemann, J. Tetens

Dynamic changes in plasma triiodothyronine concentrations before and after introduction of newly hatched chicks **552**
C. Murai, T. Kuwayama

Investigations into the farrowing process of organic sows in free farrowing systems **553**
K. Schlegel, A. S. Schintag

Quality parameters of eggs from conventional and organic hens in mobile housing systems **554**
K. Schlegel, J. Mühle

Influence of a consistent arginine supply in turkey starter diets with varying protein contents **555**
D. Siebert, C. Scharch

Impact of particle size and homogenisation on water populations measured by LF-NMR in poultry meat and its impact on water-to-protein ratio **556**
M. Balasubramani, E. Silletti, C. Alvarez Garcia

Influence of mash feed particle size selection on feed intake patterns and performance in laying hens **557**
E. Chevaux, C. Villot, A. Sacy

Possible association between live weights and plumage or skin damages in laying hens 558
N. Volkmann, A. Riedel, N. Kemper, B. Spindler

Helminth infections in free-range laying hen flocks in Lower Saxony: status-quo, reduction strategies and evaluation of appropriate diagnostic methods 559
J. Weidemann, M. Eilers, D. Jacobs, N. Kemper, J. Schulz, B. Spindler

Comparative evaluation of housing systems on immunological, physiological, and productive performance in laying hens 560
Y. Wein, M. Subhi, S. Rubin, S. Mabjeesh, I. Yoselevitz, K. Shmuel, A. Friedman

Stopping detoeing in broiler breeder males is possible 561
R. Van Emous

Breeder farm environment and age as primary drivers of offspring performance and gut microbial succession in broiler chickens 562
G. M. Pangga, A. Richmond, S. Bamford, G. Koulianos, N. Corcionivoschi, A. Psifidi, D. Xia, U. Z. Ijaz, O. Gundogdu

Session 27. Plenary session

Date: Tuesday 8 September 2026; 8:30 - 12:30
Chair(s): Spoolder, De Campeneere - Session Type: Plenary session

Theatre Session 27

Feeding the future: Global challenges, risks, policy solutions and the role of livestock production 563
N. El Benni

Navigating the perfect storm: Between Green Deal ambitions, CAP reform, and market realities 564
A. Matthews

Unpacking the promises of technology in farming: The economic challenge 565
H. Hogeveen, M. Van Der Voort

Beyond pure productivity: The strategic role of genetics, resilience, and health for business continuity 566
W. Rauw

The other side of a Curriculum Vitae: A case study in animal science 567
G. Bee

Session 28. FABRE-TP Economics of genomic improvement, and its contribution to improve animal productivity while reducing environmental impact

Date: Tuesday 8 September 2026; 14:15 - 17:15
Chair(s): Cartick - Commission(s): G - Session Type: Theme session

Theatre Session 28

Economics of Genomic Improvement: How to Enhance Productivity While Reducing Environmental Impact 568
G. Cartick, L. Fontanesi

What kind of breeding for a sustainable livestock production worldwide? global priorities, constraints, and pathways forward 569
G. Leroy, P. Ajayi, A. Uwizeye, N. Rakotovao, P. Boettcher

Challenges in breeding for reduced environmental impact and other eco-system services 570
P. Berg

Unlocking genetic progress: importance of data-driven selection to enhance productivity, economy and environmental impact 571
L. P. Sørensen

Balancing profit, greenhouse gas emissions and resilience in dairy cattle breeding using integrated modelling approaches 572
R. Shi

Investments in modern genomics and digital phenotyping to improve the economics of livestock production systems 573
D. Bickhart, N. Duijvesteijn

European integration of phenotyping, genomic and data research facilities to foster sustainable animal production and aquaculture 574
E. Labussiere, R. Baumont

Session 29. Multi-omics data integration in animal breeding

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Pocrnic, Bickhart - Commission(s): G - Session Type: Industry session

Theatre Session 29

Image-derived latent features as digital biomarkers for large-scale genetic evaluation 575
M. Billah, M. Bermann, C. Y. Chen, E. Psota, B. Valente, J. Holl, I. Misztal, D. Lourenco

Extending Single-Step Genomic Evaluations to Phenomics and Intermediate Omics: A Conceptual and Methodological Perspective 576
N. Gengler, A. Genin, A. Markey

Metabolic signatures after genetic selection of litter size homogeneity and resilience in a maternal rabbit line 577
C. Chandrababu Shailaja, M. J. Argente, M. L. García-Pardo, P. Hernández, M. Martínez-Álvaro

Resolution matters: 16S rRNA and Shotgun Metagenomics in estimating microbiome-mediated genetic variance in Iberian pigs 578
L. Azouggagh, C. Casto-Rebollo, L. Varona, J. Casellas, S. Negro, N. Ibañez-Escriche

Does the inclusion of microbiome data enhance genetic evaluations? Evidence from GBLUP and GO-BLUP comparisons in beef cattle 579
S. N. Saez-Torillo, T. Q. Nguyen, J. Lima, M. A. Cleveland, R. Roehe, M. Martínez-Álvaro

Evaluating the Contribution of Microbiome Information to Genomic Prediction for Growth, Feed Intake, and Carcass Traits in Angus Cattle 580
R. Magalhaes Da Costa, F. Bussiman, A. Garcia, K. Retallick, D. Lourenco, J. Lourenco

Integrating functional SNVs with mRNA isoform expression in A1A1 and A2A2 Holstein dairy cows 581
L. Jiménez Montenegro, O. Urrutia Vera, Á. Cánovas

Effectiveness of DNA Sequencing and Biochemical Methods in Characterizing Bovine Milk Protein Variants 582
Y. Liu, E. Bijl, J. Gao, R. Gonzalez-Prendes, M. A. Groenen, J. Kantanen, C. Ginja, N. Ghanem, D. Kugonza, M. Makgahlela, H. Bovenhuis, R. P. M. A. Crooijmans

Multi-evidence driven triage of candidate genes for feather pecking behaviour in chickens 583
C. Falker-Gieske, J. Bennewitz, J. Tetens

Utilising genotype and transcriptome information for feather pecking analysis in laying hens 584
U. S. T. Yarra, V. Haas, J. Bennewitz, J. Tetens

From genotype to phenotype: mapping shared regulatory architecture of cattle metabolome and transcriptome 585
P. K. Chitneedi, G. C. M. Moreira, C. Li, D. Fischer, C. Charlier, G. Plastow, J. Vilkki, R. Weikard, C. Kühn

Comparative profiling of the bovine plasma proteome using Olink proximity extension assay and LC–MS/MS before and after calving 586
M. Bhati, E. Paxton, L. Morrison, A. Tenesa

Genetic Score Omics Regression to Map Genes Underlying Stillbirth and Gestation Length 587
M. Zölch, A. M. Križanac, C. Schmidtmann, H. Alkhoder, J. Tetens, J. Bennewitz, M. E. Goddard, R. Xiang

Poster Session 29

Transcriptomic signatures associated with intramuscular fat deposition in the Black Slavonian pig 588
B. Lukic, G. Lipavic, M. Bulaic, I. Curik, Z. Radisic, R. Luzaic, N. Raguz

Session 30. Beef on Dairy (II): Management concepts, mating strategies and technologies for sustainable dairy and beef production

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Meier, Dohme-Meier - Commission(s): C - Session Type: Theme session

Theatre Session 30

Genetic and genomic strategies for advancing sustainable beef-on-dairy systems 589
D. Lourenco, M. Bermann, A. Cesarani, I. Misztal

Balancing profit and calving performance: New breeding values for Beef-on-Dairy sires 590
C. Schmidtmann, A. Rolfes, M. Wobbe, L. Polman, D. Adekale

Early lactation prediction of extended lactation milk yield class using random forest models in pasture-based dairy systems 591
S. L. Bird, N. Lopez-Villalobos, C. J. Andrews, S. J. Hendriks, J. P. Edwards

Comparative Machine Learning for predicting late-lactation productivity in dairy cows. 592
Y. Aarts, E. Burgers, E. Saccenti, R. Torres, R. Goselink, A. Van Knegsel

Impact of the use of Beef-on-Dairy on milk yield, calving traits and culling risk of the cow in subsequent lactation 593
L. Völker, C. Schmidtmann, L. Hüneke, G. Thaller

Splitting the bill at the gate: Pricing system to reward management and genetic potential of Beef on Dairy calves 594
K. K. Johansen, B. H. Nielsen, R. D. Kring

HerdPlanner: Decision models for reproduction and culling decisions **595**
E. Harms, R. Kool, M. Hagens, I. Adriaens, M. Sol

Fattening and slaughter performance of crossbred, German Holstein and Simmental bulls fed with sweet white lupine as protein source **596**
A. Boldt, H. Sievers, I. Papstein, P. Sanftleben

Post-weaning feed management of Holstein and beef × Holstein cattle: Effects on growth performance and carcass merit **597**
E. E. Cornand, S. A. Terry, G. O. Ribeiro, M. D. Jelinski, Ó. López-Campos, G. B. Penner

Effect of the inclusion of cocoa bean shells in the diet of fattening beef on live performance, carcass traits, and nutritional quality of the meat **598**
A. Nudda, S. Carta, M. F. Lunesu, G. Battacone, S. P. G. Rassu, F. Correddu, G. Pulina

Poster Session 30

An integer programming approach to optimal selection and mating for herd improvement **599**
I. Lagarde, E. Harms, M. Sol

Session 31. When genetic potential meets production reality: implications for the animal

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Boyle, Huber, Baes, Sauerwein - Commission(s): PH, HW, C - Session Type: Challenge session

Theatre Session 31

Characterizing the complex genetic architecture of SINS reveals associations with physiological side effects of selection in swine **600**
G. Reiner, K. Gerhards, M. Lechner, K. Koenders-Van Gog, S. Becker

Genetics of swine inflammation and necrosis syndrome: What do we know so far? **601**
N. G. Leite, A. O. Garcia, R. Vogelzang, L. Vargovic, S. Nuphaus, Ø. Nordbø, M. Londoño-Gil, J. Dunkelberger, E. Grindflek

Ear necrosis: Evidence of pigs reaching their biological limits? **602**
L. Markland, F. Leonard, K. O'Driscoll, L. Boyle

Pathological investigation of cardiovascular disease in broilers **603**
I. Thøfner, T. A. S. Al-Saeedi, S. S. Nielsen, S. Kabell, J. P. Christensen

From behavior to immunity: Sex-related differences in immune cell composition in chicken lines selected for high and low feather pecking **604**
T. Hofmann, W. Bessei, V. Stefanski, S. Schmucker

Investigating differential gene expression in the pectoral muscles of broiler chickens affected by wooden breast condition **605**
M. Bordini, S. Gioiosa, M. Petracci, F. Soglia

Mapping production independent mastitis risk in German Holsteins using GWAS SEM **606**
L. A. Gutekunst, V. P. Haas, C. Schmidtmann, J. Tetens, G. Thaller, J. Bennewitz

From genetic potential to robustness: insights from energy-allocation models **607**
F. Douhard, J. Raoul

From genotype to phenotype: expectations and limitations 608
K. Huber

Balanced breeding goals: genetics as part of the solution to livestock welfare and sustainability challenges 609
C. Baes, A. Harlander, S. Barbut, B. Wood, F. Miglior

Why laying hens struggle with vertical space: biomechanical constraints and implications for aviary design 610
A. Harlander, B. Tobalske, R. Garant, J. Page, N. Van Staaveren

When genetic potential meets production reality: implications for the animal. Discussion and summary of the session 611
K. Huber, H. Sauerwein, L. Boyle, C. Baes

Poster Session 31

Rumen-protected B vitamins improved growth potential of female dairy calves after weaning 612
R. Roszkos, U. Blaeser, D. Bouchut

Genetic Variant Mapping Across Multi-Tissue Transcriptomes Reveals Genome-wide Regulatory Signatures in Bovine IVP and MOET Calves 613
U. Gk, P. P. Pathade, J. Bojsen-Møller Secher, H. Kadarmideen

Milk yield dynamics reflect health of dairy cows in early lactation 614
B. De Bruijn, I. Van Dixhoorn, B. Kemp, A. Van Knegsel

Liver hemorrhages and keel bone fractures in experimental cohorts of two high-performing laying hen strains from week 30 to week 42 of age 615
L. Ruda, L. Messmer, V. Sommerfeld, M. Rodehutscord, K. Huber

Different motility of frozen semen between Holstein and Jersey bulls under heat stressed condition 616
S. W. Kim, J. Lee, G. Ryu, H. Baek

Phenotypic characterization of milk-derived liver enzymes and their associations with production traits in Holstein cows 617
I. Drzaic, V. Brajkovic, N. Raguz, M. Oroz, M. Oroz, M. Shihabi, M. Didara, I. Curik, B. Lukic

Session 32. Feeding strategies to optimise welfare

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Stergiadis, Franchi - Commission(s): N, HW - Session Type: Theme session

Theatre Session 32

The effect of half dose of colostrum replacer on immunity, feed intake, nutrient digestibility, and performance of dairy calves 618
M. Ravanetti, A. Collura, G. Bonacini, C. Balbo, G. Esposito

Association between passive immunity status on disease incidence and therapeutic interventions in dairy calves 619
J. V. Santos E Silva Mesquita, J. B. Daniel, J. Echeverry-Múnera, K. Iakhiaeva, D. R. Martinez Mayorga, J. Martín-Tereso, J. N. Wilms

Effect of incorporation a spray-dried fat concentrate containing tributyrin and tricaproin into milk replacer on the need for medical interventions in newborn calves. **620**
K. Iakhiaeva, J. Echeverry-Múnera, J. B. Daniel, J. Martín-Tereso, J. Steinhoff-Wagner, M. Janssen, J. N. Wilms

Digestive development and behavior in calves weaned on hay or concentrate diets **621**
X. Zhao, M. Jamrogiewicz, M. Przybyło, J. Flaga, J. Kański, D. Wojtysiak, R. Miltko, S. Ortmann, M. Niu, P. Górka, M. Clauss

Effects of calf dry TMR and warm-air-dried hay as sole solid feed on growth and behavior of pre-weaned calves **622**
J. J. Hayer, F. Leixner, G. Hellmann, T. Scheu, C. Koch, G. Dusel, J. Stracke

Factors influencing voluntary free water intake of Holstein calves with high milk replacer allowance and slow, late weaning **623**
C. S. Ostendorf, J. Steinhoff-Wagner, K. J. Hemmert, F. Leixner, C. Koch, M. H. Ghafarri

Motivation of dairy cows to access food diversity in an operant conditioning task **624**
L. Herve, R. Delagarde, A. Favreau-Peigné, C. Ginane

Enhancing mineral bioavailability, stress resilience and welfare using magnesium phosphate: evidence from in vitro models and swine in vivo trials **625**
B. Ribeiro, A. Lecointe, E. Dupuis, M. Brunon, J. Le Douce, E. Pagot, E. Coudert, A. Juanchich

Influence of dietary tryptophan-to-lysine ratio and level of large neutral amino acids on performance, lesion scores and behaviours of weaned piglets **626**
J. Glinubon, J. E. Bolhuis, A. J. M. Jansman, N. Kelderman, E. Bruininx, W. J. J. Gerrits

Comparison of two commercial 6-phytases on growth performance in a dose response trial with weaned Piglets **627**
R. Khurana, X. Guan, V. Lagos, M. Schmidt, R. Janßen

Effects of Early-Lay Prebiotic Supplementation with Galacto-oligosaccharides on Severe Feather Pecking and Associated Feather Damage in Laying Hens **628**
A. L. Nicklas, N. Van Staaveren, A. K. Shoveller, A. M. Edwards, P. Forsythe, A. Harlander

Location Matters: Impact of Pecking Block Placement on Feather Condition in Laying Hens **629**
E. Simmonds, A. L. Nicklas, N. Van Staaveren, T. Widowski, A. Harlander

Impact of dietary amino acid supply on milk urea and urine nitrogen excretion and energy corrected milk of dairy cows fed hay-based diets **630**
F. Righi, R. Pitino, E. Tsiplakou, M. Simoni

Poster Session 32

Whole plant vetch silage as roughage for growing pigs: Effects on growth performance, slaughter characteristics and outdoor run use **631**
S. Witten, J. Wiskandt, M. T. Machner, R. Bussemas, K. Aulrich

Betaine supplementation in adult goats exposed to heat stress conditions **632**
F. J. Giráldez, A. Díaz Reyes, S. Bettini, M. Dehnavi, M. J. Ranilla, L. Abdennebi-Najar, S. Andrés

Effects of live and inactivated yeasts on ruminal pH and redox potential (Eh) in dairy cows under high-carbohydrate challenge **633**
B. Dominique, C. Alexandra, R. Robert

Live yeast supplementation modulates recovery of rumen function and performance following subclinical ruminal acidosis in dairy cows **634**
M. Terré, A. M. Hanzek, M. Gindri, E. Chevaux, C. Villot

Synergistic Co-fermentation of Palm Kernel Cake Enhances Nutrient Digestibility and Modulates Rumen Microbiota in Beef Cattle 635
H. Mi, Z. Wang, C. Zhou, D. Xiao

Exploratory investigation of maternal care and early postnatal calf behavior related to milk intake in a dam-bound rearing system in the first 24 hours after birth 636
J. Kurek, A. Neuser, T. Nutto, A. Kurek, J. Steinhoff-Wagner

Session 33. Unravelling the next generation animal nutrition: functional feed ingredients and additives - Part 1

Date: Tuesday 8 September 2026; 14:15 - 17:45
Chair(s): Alvarez-Rodriguez, Kar, Foggi - Commission(s): N - Session Type: Theme session

Theatre Session 33

The effect of 3-sialyllactose in combination with Bacteroides thetaiotaomicron isolated from Ningxiang pigs on the intestinal development of piglets 637
B. Tan, L. Zhang, J. Wang

Investigating the optimal histidine to lysine ratio in piglets: impact on performance, blood parameters and carnosine content in the skeletal muscle 638
D. Siebert, K. Schuh-Von Graevenitz, G. Dusel

Effects of dietary carob pulp as a source of non-starch polysaccharides on carcass traits and fatty acid composition in intensively reared Iberian crossbred pigs 639
J. Álvarez-Rodríguez, C. M. Muñoz-Sastre, J. Santana-Sánchez, M. Á. Latorre

Integrating growth performance and tissue functional transcriptomics to elucidate the effects of a xylanase and β-glucanase combination in post-weaning pigs 640
P. Aymerich, E. Ball, L. F. Romero, D. E. Velayudhan, M. A. Ton Nu, R. Muns, Y. Dersjant-Li, E. Vinyeta

Effects of dietary γ-aminobutyric acid supplementation on growth performance and novel object test responses in nursery piglets 641
E. Huenul, J. F. Pérez, D. Saavedra, K. Rochina, S. M. Martin-Orúe

Magnesium-protected zinc as an alternative to zinc oxide on growth of weaned piglets 642
R. Aureli, Z. Garlatti, E. Bacou, J. Le Cour Grandmaison

Microalgal Chlorella sorokiniana as a functional feed ingredient improves post-weaning piglet performance 643
S. K. Kar, A. Van Enckevort, E. Houtzager, S. J. Koopmans

Tiny but mighty: small dose of standardized dry grape extract potentiates antioxidant defenses in broiler chickens 644
P. Engler, D. Bień, S. Cissé, M. E. A. Benarbia, S. Jaworski, A. Lange, P. Ciborowska, A. Zalewska, J. Urban, M. Michalczuk, A. Matuszewski

Protective antioxidant effects of a dietary polyphenol combination in broilers under heat stress 645
J. Estévez, P. Martín-Atance, S. Haldar, A. K. Dhara, S. Sihi, S. Sawant, S. Carné

From agricultural residue to high-value prebiotics: Upcycling sorghum lignocellulosic biomass into cello-oligosaccharides 646
N. Mahna, S. Kumar, A. K. Samanta, S. Arora

EntoBoost: a multi-model screening platform to identify and study insect fractions with health-promoting effects in animal feeds **647**
N. A. Sibinga, E. Fako, M. Kraft, J. Nerinckx, V. Vermeylen, J. De Smet, A. Declercq, N. Everaert

Antioxidant Supplementation in Maternal Diet Modulates the Effects of Season on Swine Progeny **648**
A. Magro, P. Vázquez, G. Gómez, J. García-Casco, F. Sánchez, C. López-Bote, C. Óvilo, M. Muñoz, A. Heras-Molina

Poster Session 33

Immunomodulatory effects of nucleotide-based formulations enriched with seaweed and olive bioactive compounds in mammals: evidence from an LPS-induced rat model **649**
S. Segarra, J. Teichenne, R. Mariné-Casadó, A. Mas-Capdevila, J. M. Alcaide-Hidalgo, A. Antolín, D. Martínez-Puig, J. Velasco-Alvarez, A. Caimari

Anti-inflammatory effect of Cyanidin-3-O-lathyroside from Eleutherococcus sessiliflorus in LPS-induced in vitro model **650**
A. J. E. Cabuloy, C. H. Lee, M. S. Kim, S. H. Kim

Effects of a phytogenic blend of capsicum, clove and garlic in starter feed on the growth performance of Holstein dairy calves. **651**
R. E. Crossley, S. Torrey, S. Van Kuijk

Natural bioactives preserve gut resistome stability in broilers compared with antibiotic growth promoters **652**
R. Andreaki, P. Kyriakaki, S. Koulocheri, A. Pappas, A. Mavrommatis, E. Tsiplakou

Evaluation of thinned apple by-products in ETEC F4-challenged weaned piglets **653**
M. Tretola, P. Lin, F. Bertolin, L. Pinotti, P. Silacci, N. Pradervard, G. Bee, M. Girard

Supplementation of a porcine-derived bioactive complex in the diet reduces post-weaning diarrhea and modulates gut microbiota in ETEC-challenged piglets **654**
I. Bez, M. Blanc, C. Cintra, R. Nunes, G. Stofella, S. Weber, L. Costa

Improving Zootechnical Performance of Broilers with Polyphenol Blend **655**
M. Osredkar Mergole, V. A. Rios De Castilho Heiss, S. Molino, O. Desrues, E. Santin

Session 34. Precision livestock feeding: Innovations and technologies optimizing animal welfare, productive performance and feed utilization

Date: Tuesday 8 September 2026; 14:15 - 17:45
Chair(s): Montanholi, Casasús - Commission(s): PLF, N - Session Type: Theme session

Theatre Session 34

Assessing accuracy and on-farm applicability of dairy cow feed intake prediction equations **656**
M. Gierus, S. Steiner, L. Dardabou, G. Terler

Accuracy of five dry matter intake prediction models in lactating dairy cows across energy-corrected milk yield classes: a meta-analysis **657**
U. Serbester, A. G. Aydoner, P. Y. Bozkaya, Z. Cebeci

Use of real-time forage-harvester NIRS to reduce whole-plant maize silage nutrient variability through dynamic cutting-height control **658**
J. L. Monge

Artificial intelligence applied to feed delivery in dairy farms 659
A. J. De Paula Nunes Cassimiro, E. Da Silva Ramos, C. D. De Sousa Bezerra, R. A. Pereira Franco, A. Assis Cardoso, E. Noronha De Andrade Freitas

A pilot study integrating jaw accelerometry and surface electromyography for automated monitoring of chewing dynamics in cattle 660
R. Zsoldos, S. Meale, O. Guzhva

Comparative assessment of 3-dimensional camera and GreenFeed systems for on-farm feed efficiency evaluation 661
A. Guinguina, J. Nousiainen, P. Huhtanen

SipControl: High-resolution pressure sensing to characterize granular sucking behavior in automated calf feeders 662
E. Johannhardt, A. Deininger, M. Gültas

Evaluation of non-invasive sensors for monitoring vital signs in dairy cows using pulse oximetry and infrared thermometry 663
M. González-Cabrera, V. Hernández, J. Muñoz-Quirós, A. Morales-Delanuez, A. Argüello, N. Castro, L. E. Hernández-Castellano

Use of computed tomography to predict commercial lamb cut weights 664
Y. Huo, H. Calnan, G. Gardner, F. Anderson, L. Pannier, D. Gutzke

What does outdoor access cost? A mechanistic analysis of energy expenditure in free-range slow-growing chickens 665
G. Dukhta, Y. Guyot, S. Chaumont, S. V. Mignon, E. Pampouille, B. Méda

Early prediction of growth dynamics and feed conversion ratio using random forest regression models in growing pigs 666
V. Ács, G. Kövér, G. Bee, V. Halas

Opportunity for welfare breeding: An automated registration system to record foraging activity of individual pigs as an indicator trait for positive welfare 667
R. M. Zaalberg, J. Malmkvist, N. S. Madsen, M. L. V. Larsen, J. D. Bus, T. T. Chu, R. Thomsen, H. Bovbjerg, L. J. Pedersen

Poster Session 34

Impact of bronopol preservation on milk metabolomic stability 668
N. Frías-Reid, R. R. Lobo, G. Conta, J. L. Mejía Méndez, D. E. Navarro López

Pilot GWAS of male reproduction traits in Slovak farmed Rainbow trout 669
R. Kasarda, N. Moravčíková, A. Halvoník, K. Pálešová, J. Andreji, M. Fik

Modelling post-farrowing body weight in sows from gestation and litter data 670
N. Quiniou, J. Thomas, A. Letort

Analysis of fecal particle distribution in dairy cows with different assessment approaches 671
H. Scholz, L. Hentschel, P. Kühne

Methane Yield Integrated into Feeding Strategies as a Measure of Production Efficiency in Tropical Commercial Dairies: Case Study in Tamil Nadu, India 672
K. M. Tirimba, T. Ravichandran, M. G. G. Chagunda

"Collar-Tag": A Novel, Rapid, and Secure Electronic Identification Method for Lambs 673
F. Chessa, N. Lei, L. Mara, G. Epifani, M. Dattena, V. Giovanetti, N. Charbel

Session 35. Early career competition (pigs& poultry)

Date: Tuesday 8 September 2026; 14:15 - 17:45
Chair(s): Chalvon Demersay, Bordignon, Arnaud - Commission(s): P, PO - Session Type: Theme session

Theatre Session 35

Can feed color drive feeding behavior in piglets? **674**
O. Tej, J. Leskovec, M. Colom-Pellicer, C. Güell Saperas, M. Ferrando Cogollos, D. Torrallardona

Chronic stress reshapes the pig gut microbiome: insights from metaproteomics **675**
R. Río-López, J. Guitart-Matas, M. Ø. Arntzen, A. Clavell-Sansalvador, I. T. Voularki, O. González-Rodríguez, L. J. García-Gil, X. Xifró, A. Dalmau, Y. Ramayo-Caldas

Step into the Udder Zone – Identifying behavioural proxies of fallback piglets under heavy occlusion **676**
S. P. Brouwers, C. Ducrue, L. A. Boyle

Influence of different sow and farrowing parameters on colostrum quality in a free farrowing system **677**
P. T. Egli, J. Adam, C. Rüegg, G. Schüpbach-Regula, J. J. Gross, A. Grahofer

Effect of early and late postnatal administration of two artificial colostrum formulas on piglets' growth performance, blood metabolic profile and intestinal health **678**
S. Bencivenni, E. Huenul, F. Palumbo, M. Mazzoni, G. Metti, G. Rocchetti, F. Correa, D. Luise

Modulation of Dietary Acid-Binding Capacity by Limestone Flour Omission and Fumaric Acid Supplementation in the First 14 Days Post-Weaning: Effects on Pig Performance and Health **679**
J. Glynn, G. Gardiner, J. O'Doherty, T. Sweeney, P. Lawlor

Effect of dietary inclusion of a by-product of Gelidium sesquipedale on post-weaning growth and health of pigs **680**
C. Negrini, J. Glynn, G. Gardiner, R. Oliver-Simancas, A. Jiménez-Quero, L. Giblin, P. Lawlor

Effects of the combination of potentiated zinc oxide and monovalent copper in low acid-binding capacity-4 diets on growth performance and plasma zinc and copper concentrations **681**
J. Lee, M. Tokach, J. Derouchey, A. Monteiro, Y. Manaig, P. Trevisi

Effect of Lactiplantibacillus Plantarum on nitrogen, calcium and phosphorus balance in weaned piglets challenged with Fumonisins B1 **682**
L. Ikanya, B. Libisch, T. Keresztény, F. Olasz, M. Kovács, V. Halas

Evaluating social genetic models in pigs with precision feeding data and stochastic simulation **683**
P. Nuñez, L. Varona, J. Casellas, N. Ibáñez Escriche

Enrichment with live insect larvae (Hermetia illucens) on productive results in slow- and fast-growing broiler chickens **684**
M. Pravato, M. Cali, F. Bordignon, D. Meo Zilio, M. Molin, S. Caré, S. Bellezza Oddon, A. Trocino, G. Xiccato, D. Bochicchio

From tissue to transcriptome: Exploring differential gene expression in porcine scrotal hernia using a QuantSeq approach **685**
J. De Kort, S. Van De Voorde, B. Chakkingal Bhaskaran, R. Meyermans, K. Hooyberghs, S. Janssens, N. Buys, W. Gorssen

Session 36. From threat to response – biosecurity in times of African Swine Fever, Avian Influenza and other infectious diseases

Date: Tuesday 8 September 2026; 14:15 - 17:15
Chair(s): Holinger, Goszczynski - Commission(s): HW, SG, PO, P, C - Session Type: Industry session

Theatre Session 36

Biosecurity in challenging times: recognizing overlooked hygiene pathways in livestock production **686**
N. Kemper

Live animal transport and disease spread: the public health case for meat and carcass trade **687**
E. Massalin, M. Klimczak

Toward oral African swine fever vaccines: Harmonized evaluation and strategy optimization **688**
T. Holzum, V. Friedrichs, U. Blohm, M. Beer, S. Blome, A. Schäfer

Staphylococcus aureus at the Wildlife–Livestock Interface: Occurrence and Genomic Characterization in Northern German Production Systems **689**
R. H. Mateus-Vargas, I. Grafelmann, K. Büter, T. Fenker, J. Tetens, J. A. Hammerl, T. Lienen

Identifying the immunocompetence markers at weaning to predict vaccine response and persistence in pigs **690**
A. A. M. Sabuj, C. Denis, J. Estellé, C. Rogel-Gaillard, M. H. Pinard-Van Der Laan, F. Blanc

Semen storage at 5 °C enables omission of antibiotics in artificial insemination of pigs under field conditions **691**
F. Reckinger, A. Riesenbeck, A. M. Luther, I. K. Maaßen, R. Waßmuth, D. Waberski

Exploration of somatic cell counts in sow colostrum **692**
R. Muns, C. Mulvenna

Elevated blood glucose in late gestation is associated with increased mortality, particularly in gilts **693**
F. R. Dunshea, R. Clarkson, K. Mcdermott, M. Magnon, S. O'Connell

Aligning veterinary recommendations, farmer adoption, and costs of preventive measures for production diseases in Danish dairy herds **694**
O. U. Lønberg-Jensen, V. M. Thorup, S. Østergaard

Poster Session 36

Mastitis in sows and its implications for colostrum quality **695**
R. Muns, C. Mulvenna

Assessment of the economic impact of swine influenza on Japanese swine commercial farms **696**
T. Suzuki, J. Mine, K. Miayzawa, Y. Uchida, Y. Mizoguchi, Y. Sasaki

Analysis of factors associated with preweaning mortality and cause-specific mortality **697**
T. Sakakura, Y. Sasaki

Tricks of the trade: understanding cattle purchasing in the context of an endemic statutory disease and associated control efforts **698**
A. Ferreira, N. L. Field, U. Kenny, C. G. Mcaloon, J. F. Mee, E. J. Murray, Á. Regan, A. W. Byrne

Session 37. Omics for functional traits in horses

Date: Tuesday 8 September 2026; 14:15 - 15:45
Chair(s): Tan, Meyermans - Commission(s): H - Session Type: Theme session

Theatre Session 37

Genetic population structure and genomic associations with coat colour and conformation traits in the endangered Schleswig cold blood horse **699**
S. C. Blomeyer, J. Stuhlträger, K. F. Stock, H. H. Swalve

Genetic investigations of the roan coat color in Icelandic horses: Population analyses and candidate variants on ECA3 **700**
K. Voß, I. Blaj, D. Becker, G. Thaller

Towards a comprehensive screening approach for detecting gene doping in racehorses and sport horses by targeting common and intrinsic plasmid sequences **701**
A. Paz, S. Dhorne-Pollet, B. Loup, F. André, P. Garcia, L. Bailly-Chouriberry, E. Barrey

Wearable-based continuous monitoring and omics profiling of thermal and exercise resilience in Thoroughbred racehorses **702**
S. Mecocci, R. Ratto, E. Porzio, M. Pepe, G. Chillemi, E. Chiaradia, F. Beccati, K. Cappelli

Mitochondrial and genomic factors in equine Recurrent Exertional Rhabdomyolysis **703**
L. Pavlin, S. Dhorne-Pollet, M. Filipe-Ferreira, M. Bernard, A. Ricard, E. Barrey

Prevalence of equine missing eyes (Microphthalmia and Anophthalmia) with sex skewed inheritance and parent-of-origin effect **704**
V. Asti, Å. Gelinder Viklund, S. Mikko

Poster Session 37

Long-read mitochondrial DNA sequencing for genetic variability analysis in endurance horses **705**
S. Dhorne-Pollet, N. Pollet, M. Filipe Ferreira, C. Robert, E. Barrey, A. Ricard

Systemic Transcriptomic Mirroring: Unveiling the Neuro-Muscular Axis and Non-Invasive Biomarkers for Elite Racing Performance in Horses **706**
J. W. Park, J. M. Kim, K. S. Lim, J. E. Park, D. Shin

Circulating miRNAs and biochemical markers to evaluate heat-stress responses in Sicilian horse breeds **707**
M. Carlentini, S. Tumino, A. Antoci, G. Chessari, A. Criscione, S. Bordonaro, D. Marletta

Session 38. Advances in insect breeding and genetics

Date: Tuesday 8 September 2026; 16:15 - 18:00
Chair(s): Meyermans, Rumbos - Commission(s): I, G - Session Type: Theme session

Theatre Session 38

Selective breeding in insects - state of the art and prospects **708**
H. M. Nielsen, T. Nygård Kristensen, G. Gebreyesus, H. G. Tariku, R. M. Zaalberg, L. S. Hansen

Global patterns of genomic variation in ten domesticated Black Soldier Fly (Hermetia illucens) strains **709**
F. Ijdema, M. Verschaeren, L. Broeckx, L. Frooninckx, J. Bouhuijzen Wenger, J. De Smet, S. Van Miert, N. Buys, R. Meyermans

Estimating variance components and breeding values in honeybee populations via spatially aware simulation 710
N. Pustovrh, G. Gorjanc, J. Obsteter

Integrative multi-omics analysis reveals genetic variants associated with growth traits in the superworm (Zophobas atratus) 711
A. Sode, N. Jeßberger, N. T. Grabowski, C. Schwennen, M. Plötz, C. Visscher, J. Metzger

On the change of heritability and genetic correlations over time in honeybee breeding 712
A. Hoppe

Genotype × Environment and the gut microbiome shape Hermetia illucens performance: insights from 14 Lines across three diets 713
F. Ijdema, M. Verschaeren, L. Broeckx, L. Froninckx, S. Van Miert, N. Buys, R. Meyermans, J. De Smet

Poster Session 38

Genetic progress in honeybee population under selection depending on mating design – a simulation study 714
S. Andonov

Evidence for adaptation to divergent diets in black soldier flies using an experimental evolution set up 715
M. D. Mogensen, M. S. Christiansen, L. S. Hansen, H. M. Nielsen, R. M. Zaalberg, T. N. Kristensen

Determining the Minimal Viable Population Size of the Black Soldier Fly (Hermetia illucens) over Ten Generations of Inbreeding 716
M. Verschaeren, L. Froninckx, L. Broeckx, R. Meyermans, F. Ijdema, N. Buys, J. De Smet, S. Van Miert

Session 39. Enhancing circularity in sustainable livestock systems: innovations, technologies and strategies

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Mantino, Salami - Commission(s): LFS - Session Type: Industry session

Theatre Session 39

Circular Feed Ingredients in Livestock Systems: Opportunities and Constraints for Circular Agriculture 717
A. Khimasia

Food loss and waste to animal feed – an imperative for a circular, sustainable, One Health food system 718
G. Shurson, Z. Dou

Qualitative and quantitative analysis of meat by-products in France to enhance circular bioeconomy 719
V. Landais, B. Duflot, T. Bonaudo, R. Baumont

Competitive resources in dairy cattle feeding: effect on yields, efficiency and emissions 720
M. Berton, L. Gallo, E. Sturaro

Closing the loop in Mediterranean lamb production: Circular economy benefits of cucumber–straw silage evaluated through in vitro, in vivo, and life cycle assessment 721
M. Hassan, A. Belanche, N. Davison, M. Romero-Huelva, L. G. Smith, D. R. Yañez-Ruiz

Advantages of an ensiled total mixed ration including sugar beet pulp for French dairy farms **722**
A. Roméo, R. Delagarde, J. Duponchel

Ensiling by-products: destoned olive pomace silage as an on-farm strategy for lamb meat production to reduce food/feed competition and enhance meat quality **723**
F. G. Cella, T. Malizzi, M. Finocchi, E. Senatore, A. Silvi, A. Ripamonti, A. Mantino, G. Conte, A. Serra, M. Mele

What intrinsic levers do mixed crop–livestock farmers in Guadeloupe have to improve the agroecological performance of their farms? **724**
N. Mandonnet, A. Fanchone, M. Eugene, E. Laclef, C. Latchman, G. Pioche, F. Stark, B. Dumont

Energy-Plus Dairy Farming – Evaluating the Decarbonization Potential of Integrated Biogas and Photovoltaic Systems in Northern German Milk Production **725**
J. Drews, J. Koerte, S. Krueger, P. Sanftleben

Effects of nitrogen fertilization, biorefinery processing and season on nitrogen fractions in grasses **726**
M. Gomes, N. Hansen, M. Weisbjerg, S. Jensen

Greenhouse gas emissions of grass-based dairy systems: insights from nutrient cycle assessments of Dutch dairy farms **727**
G. Bonekamp, L. De Jong, N. Van Eekeren, J. Pijlman

Session 40. Small Ruminant Genetics, Genomics, other -Omics and Breeding Advances to improve production and sustainability

Date: Tuesday 8 September 2026; 14:15 - 17:45
Chair(s): Cieleń, Rahmatalla - Commission(s): SG, G - Session Type: Theme session

Theatre Session 40

It's not always as simple as it seems: lessons from genetic susceptibility to prion and lentivirus infections in sheep **728**
G. Lühken, M. Serena Beato, K. Elisabetardottir, P. König, C. Fast, E. Grochowska, V. Beringue, S. Thorgeirsdottir

Dissecting the genetic architecture of somatic cell score in Cyprus Chios ewes: Heritability, genetic correlations with milk traits and GWAS analysis results using 50K SNP DNA microarray data **729**
S. Panayidou, T. Christofi, G. Hadjipavlou

Genetic selection as a sustainable strategy against gastrointestinal nematodes in Flemish Texel sheep **730**
A. Genin, R. Meyermans, W. Gorssen, K. Hooyberghs, E. Uchenna Nwosu, N. Buys, S. Janssens

Genetic correlations between dairy and maternal traits in the Lacaune dairy sheep breed **731**
F. Tortereau, E. Langlais, C. Allain, J. Raoul

Genetic correlations between leather pinhole defect and selected traits in Lacaune dairy sheep **732**
H. Largant, L. Drouilhet, F. Woloszyn, F. Plisson-Petit, S. Lucas, J. C. Duchêne, D. Allain, H. Larroque

Genomic insights into health resilience and environmental adaptation in Portuguese and Angolan small ruminants **733**
A. Amaral

From zero to hero – the spread of a new breed throughout a sheep industry using the Texel in Britain as an example 734
G. Pollott

Genomic insights into the genetic diversity of the Slovak Askanian merino sheep 735
A. Halvoník, N. Moravčíková, K. Pálešová, I. Pavlík, J. Tomka, L. Vostrý, H. Vostrá-Vydrová, R. Kasarda

Genomic diversity and population structure of the endangered Thuringian goat breed 736
A. W. Omar, P. Korkuć, E. Strucken, G. B. Neumann, A. Martinez, S. Carolan, G. A. Brockmann, S. A. Rahmatalla

From pedigree to genomics, studying genetic diversity and selection signatures in the Cornigliese sheep breed 737
V. Asti, M. Ablondi, M. S. Ferrari, A. Negro, S. Grande, M. Malacarne, A. Summer, A. Sabbioni

Predicting Feed Efficiency from Multi-Omics Data in Lambs Fed Two Consecutive Diets 738
Q. Le Graverand, C. Bellanger, C. Marie-Etancelin, J. L. Weisbecker, N. Marty-Grasset, M. L. Chemit, F. Tortereau

Poster Session 40

Estimation of genetic parameters for meat traits using replacement ewe lambs. 739
J. Raoul, H. Geniès, C. Burg, M. Arnal, F. Tortereau

Enhancing the sustainability of Latvian sheep breeding through genomic selection for relative growth rate and Kleiber ratio 740
N. Paramonova, M. Martins, S. Plavina, D. Malakovska, N. Krasnevska, J. Paramonovs, D. Kairisa, I. Trapina

Genetic determinism of leather pinhole defect in Lacaune dairy sheep 741
H. Largant, H. Larroque, M. C. Cadiergues, C. Allain, M. Lamarque, F. Woloszyn, F. Plisson-Petit, K. Feve, S. Lucas, J. C. Duchêne, D. Allain, S. Fabre, L. Drouilhet

Effect of Aloe vera Supplementation in a Tris-Based Cryoextender on the Post-Thaw Quality of Box-Frozen Goat Spermatozoa 742
A. G. Onal, Y. Z. Guzey

Genetic background of feed efficiency residual traits for sustainable breeding of sheep breeds raised in Latvia. 743
I. Trapina, M. Martins, S. Plavina, D. Malakovsa, N. Krasnevska, J. Paramonovs, D. Kairisa, N. Paramonova

Mapping Growth and Carcass Traits in Sheep for Sustainable, Low Emission Meat Production. 744
S. R. Chacko Kaitholil, M. H. Mooney, A. Aubry, F. I. Rezwan, M. Shirali

Genome-wide signatures of selection and genomic divergence in three autochthonous sheep breeds from Epirus, Greece 745
A. Kominakis, D. Gelia, D. Pappas, M. Goliomytis

Variation in host transcriptomic responses in three SRLV-associated tissues in relation to sheep serological SRLV infection status, TMEM154 E35K polymorphism and breed 746
E. Grochowska, O. O. Adeniyi, M. Ibrahim, K. Pokrzywka, P. Guz, G. Lühken

Metabolic stress reshapes intracellular signalling in ovine hypothalamic KNDy neurons 747
D. Zięba, E. Ocłoń

Association of C18 fatty acids, including the shift-t10, with the rumen microbiome in lambs 748
C. Manuel, S. Moradi, O. Guerreiro, E. Jerónimo, S. Alves, R. Bessa, D. M. Soares

Assessing the population structure in a recently established hair sheep population using pedigree data 749
A. M. Deidewig, E. Jonas, B. Hüttenmann, E. Tholen

Session 41. Phosphorus and other critical raw materials in poultry - joint EAAP–WPSA

Date: Tuesday 8 September 2026; 14:15 - 18:00
Chair(s): Camarinha Silva, Stadnicka, Das, Visscher - Commission(s): PO - Session Type: Theme session

Theatre Session 41

Rethinking phytate utilisation in poultry: Endogenous phytate degradation and influencing factors 750
M. Rodehutscord

Dynamics of endocrine and transcriptional profiles in phosphorus and calcium metabolism at onset of egg laying 751
H. Reyer, M. Oster, N. Trakooljul, S. Ponsuksili, V. Sommerfeld, M. Rodehutscord, K. Wimmers

Strain-Specific Molecular, Immune, Physiological, and Microbiome Shifts Along the Gut–Bone–Kidney Axis Under Mineral Phosphorus Depletion in Laying Hens 752
S. Ponsuksili, H. Reyer, M. Oster, Y. A. Abitew, N. Trakooljul, F. Hadlich, S. Schmucker, V. Stefanski, Y. H. Chien, A. Camarinha-Silva, V. Sommerfeld, M. Rodehutscord, K. Wimmers

Quantitative genetic insights into calcium and phosphorus metabolism at the peak of egg laying of two commercial laying hen strains 753
M. Schmid, V. P. Haas, V. Sommerfeld, A. Camarinha-Silva, M. Feger, M. Föller, K. Huber, M. Oster, S. Ponsuksili, J. Seifert, K. Wimmers, J. Bennewitz, M. Rodehutscord

Omics-based covariance matrices in prediction models: a case study phosphorus efficiency and poultry 754
V. P. Haas, J. Bennewitz, M. P. L. Calus

The importance of minerals and vitamins for poultry health 755
C. Visscher

Impact of feeding diets without mineral P supplement on the immune system of two laying hen strains 756
N. Wallauch, S. Schmucker, T. Hofmann, V. Sommerfeld, M. Hasselmann, K. Huber, M. Rodehutscord, V. Stefanski

Impact of myo-inositol feeding and mineral phosphorus supply on insulin signaling in liver and adipose tissue of two high-performing laying hen strains at different production stages 757
L. Ruda, Á. Szentgyörgyi, V. Sommerfeld, K. Huber, M. Rodehutscord

Risk assessment of environmental samples on the prevalence of antibiotic-resistant microorganisms in broiler fattening systems 758
T. M. Liegsalz, M. Savin-Hoffmeyer, U. Blum, C. Heinemann, J. Steinhoff-Wagner

Effect of varying dietary methionine plus cysteine concentrations on growth performance of slow-growing broiler chickens at different ages 759
P. Hofmann, A. Lemme, F. Ahrens

Random forest prediction of nitrogen utilization efficiency in broiler chickens with growth performance and dietary nutrient concentrations 760
W. Dou, T. M. Lange, W. Siegert

Poster Session 41

Metagenomic analysis reveals strain-specific ileal microbiome responses to low-phosphorus diets in laying hens **761**
Y. H. Chien, T. Yergaliyev, J. Seifert, A. Camarinha-Silva

Defatted and dehydrated avocado seed meal improves feed conversion ratio in broiler chickens at 21 days of age **762**
R. Vianna Nunes, T. Gabrieli, N. Rohloff Junior, T. Dos Santos Andrade, M. L. Dos Reis Maia, N. Borsatto, M. E. Gonsatti Costa Curta, E. M. Henz, G. Natha Comin, P. Cesar Pozza

Paraprobiotics and metabolic stress in peak-laying hens: implications for yolk lipid stability **763**
D. Rippel, C. Nueangjamnong

Modulation of systemic metabolic phenotype and growth performance in broiler chickens following in ovo administration of myo-inositol **764**
N. Shomina, V. Sommerfeld, M. Rodehutscord, K. Huber

Session 42. Challenge session: the future of pig production research: Who needs researchers if we have AI?

Date: Tuesday 8 September 2026; 14:15 - 15:15
Chair(s): Aluwé, Maselyne, Trevisi - Commission(s): P, PLF - Session Type: Theme session

Theatre Session 42

How Artificial Intelligence Could Transform Pig Farming in the Next Decade **765**
M. Marcon, M. Nouri

How AI Is Reshaping the Role of the Pig Researcher **766**
P. J. De Temmerman, J. Maselyne, M. Aluwé

Session 43. Bridging physiology and precision livestock farming: automated quantification of physiologic, metabolic and environmental disturbances

Date: Tuesday 8 September 2026; 16:15 - 18:00
Chair(s): Slootmans, Díaz de Otálora - Commission(s): PLF, PH - Session Type: Theme session

Theatre Session 43

Contributions of physiological sensors and AI-assisted videos to the study of physiological and behavioural adaptative mechanisms in growing pigs facing a heat wave **767**
C. Xavier, D. Renaudeau, L. Bonneau De Beaufort, C. Largouët, S. Brajon, F. Gondret

Heat stress in weaned piglets - respiratory rate in relation to animal behaviour and temperature-humidity index **768**
C. Meyer, I. Traulsen, N. Kemper, P. Heseker, A. Langehennig-Peristenidou, N. Dirksen, J. Probst

Effects of Temperature-Humidity Index on reproductive and productive performance in Spanish commercial sow farms **769**
S. Sanjuán, X. Díaz De Otálora, R. Arnau, J. M. Calabuig, M. Rodríguez, E. Quintana, G. Montalvo, F. Estellés

Development of a continuous MIR-based nutritional stress score using an experimental challenge in dairy goats **770**
C. Brosse, J. Pires, M. Calmels, M. Bonnet, T. Fassier, N. Friggens, R. Rupp

Physiological validation of heart rate variability as a sensor-based indicator of environmental and metabolic disturbances in grazing dairy cows **771**
D. Vallejo-Timaran, P. Betancourth-Chaves, V. Castillo-Vanegas, J. Unigarro-Charfuelan, J. Lerma-Lasso, A. Zuluaga-Cabrera, J. Montoya-Zuluaga

Actionable indicators derived from milk fatty acids to assess rumen health, negative energy balance and production losses in dairy cows **772**
I. Adriaens, E. Harms, J. Veneman, D. Schimmel, H. Taweel, R. Muller, M. Sol

Quantification of drinking-induced rumen temperature change in dairy cows **773**
H. Muraina, P. Hinke, R. Capota, R. Rivera Chacon, B. Foris

Poster Session 43

FRESHEEP&GOAT: Adapting dairy sheep and goat barns to reduce heat stress due to climate change **774**
M. Lambert, P. Massabie, J. M. Gautier, N. Litalien, G. Lagriffoul, F. Pingitore, F. Guillerault, P. Merino, E. Rosa, L. Rincón, A. Elhadi, A. A. K. Salama, G. Caja

Between-cow variation of responses to a subclinical ketosis challenge in early-lactating dairy cows **775**
A. M. Reiche, J. Hendricks, J. Eichinger, F. Robertini, M. Marchese, R. Siegenthaler, L. Eggerschwiler, G. Lazzari, P. Silacci, F. Dohme-Meier

Temporal dynamics of breath acetone and blood β-hydroxybutyrate in early lactation dairy cows **776**
J. Hendricks, J. Ko, A. M. Reiche, R. Siegenthaler, L. Eggerschwiler, A. Güntner, F. Dohme-Meier

Variability of urinary traits in lactating Holstein cows and their associations with milk quality traits **777**
S. Magro, M. Kreuzer, G. Niero, M. Penasa, E. Visentin, A. Guerra, E. Chiarin, M. Renzi, M. Simoni, F. Righi, M. De Marchi

Session 44. Methodological Innovations for Genomic Analysis and Prediction

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Bonifazi, Cieleń - Commission(s): G, PH - Session Type: Theme session

Theatre Session 44

Impact of the Bulmer effect is stronger than typically assumed when selecting on polygenic traits **778**
Y. Wientjes, M. Calus, P. Bijma

Loss of Genetic Variance in Simulation Studies: Comparing the Effect of Selection on Classical and Deep Learning based Genetic Simulation Models **779**
O. Onabanjo, T. Meuwissen, H. M. Gjøen, E. Karaman, T. T. Chu, P. Berg

Impact of non-additive genetic architecture, QTL number, and reference population size on the relative performance of machine learning and GBLUP models **780**
J. Yang, P. Duenk, M. Calus, Y. Wientjes

A novel Monte Carlo method for approximating the null hypothesis in genomic-window genome-wide association analyses **781**
D. López-Carbonell, M. Sánchez-Díaz, F. Barceló-Blasco, L. Varona

Optimising GCTA for improved parallelisation of large-scale association testing **782**
A. Leonard, N. Kadri, N. Watson, Q. He, H. Pausch

Geometrical Linkage Disequilibrium between SNPs Dominance Effects and a Quantitative Trait **783**
L. Gomez-Raya, W. M. Rauw

Misunderstood matrix: How changing the incidence matrix of social genetic effects changes the trait definition **784**
B. Hegedűs, Z. Wang, C. A. E. M. Orsini, N. Galoro Leite, J. E. Bolhuis, P. Bijma

Deriving Metafounders from Cluster-Analysis: Application to Real Data **785**
C. Edel, C. Anglhuber, E. C. Pimentel, R. Emmerling, J. Ertl

Estimating variance components and genetic parameters in large genotyped populations **786**
D. Lourenco, M. Bermann, G. Gowane, I. Misztal

Poster Session 44

Validating Indirect Genomic Predictions for Low and Moderately Heritable Traits **787**
J. Thomason, F. Bussiman, A. Lima, S. Sanchez, A. Garcia, D. Lourenco

Fine-tuning Monte Carlo single-step genomic REML for variance components estimation in large datasets **788**
M. Bernardes, M. Bermann, A. Álvarez-Munera, I. Misztal, D. Lourenco

Modelling missing pedigree using metafounders and validating genomic predictions in small sheep population **789**
A. Phillips, C. M. Rochus, J. Ramljak, Z. Barać, M. Špehar, A. Kasap, I. Pocrnić

Session 45. Advances in Genomics and Breeding Across Livestock Species

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Dodd, Schiavo - Commission(s): G - Session Type: Free communications (bottom-up)

Theatre Session 45

Visualization of changes in relationships among traits over time – example in type traits **790**
M. Misztal, I. Misztal, D. Lourenco

Establishment of a Nationwide Monitoring System for Genetic and Phenotypic Trends in German Dairy Cattle **791**
J. Gürtler, B. Albert, C. Edel, R. Emmerling, C. Schmidtmann

Temporal Dynamics of Major SNPs Identified by Large-Scale Single-Step GWAS in Broiler Chicken Populations **792**
B. Moreno, M. Bermann, F. Bussiman, N. Stafuzza, V. Likness, D. Lourenco

Enhancing individual egg number records in group-housed laying hens through integration of behavioral patterns and automated nest system records **793**
C. M. Sun, C. Reimer, A. Weigend, N. Goetzke, S. Weigend, J. Geibel

Breeding strategies for pike-perch (Sander lucioperca) in recirculating aquaculture systems in Denmark **794**
H. M. Nielsen, J. Willemijn Verweij, J. Overton, T. Boutrup, T. Tuan Chu

Optimal SNP selection for parentage discovery in large, genotyped populations **795**
A. Garcia, P. Ramos, R. Medeiros, L. Novo, K. Retallick

Partitioning the genetic architecture of reproduction traits in Holstein cattle using local heritability **796**
L. Schwarz, J. Bennewitz, J. Tetens, G. Thaller

Large-scale identification of breed-specific alleles in cattle and their potential impact **797**
J. S. Schlüter, F. Heinrich, M. Gültas, A. O. Schmitt

Detection of sex chromosome aneuploidies using SNP array intensity data: an application in pigs. **798**
M. Londoño-Gil, M. F. L. Derks, N. G. Leite, C. Sevillano, E. Grindflek

Estimation of semen variability phenotypes in boars used for artificial insemination **799**
P. Sá, R. Mezencio Godinho, E. Grindflek

Poster Session 45

easybreedeR: An integrated R shiny application for breeding data analysis **800**
H. Tang, H. A. Mulim, H. R. D. Oliveira

Towards a Stillbirth Monitoring System for German Holstein Dairy Cattle in the MGPT Project **801**
F. Fischer, L. Hüneke, L. Völker, Y. Zheng, C. Schmidtmann, G. Thaller, C. Reimer, C. Klein, C. Kühn, J. Geibel

Monitoring of Genetic and Phenotypic Trends in German Dairy Cattle – Project MGPT **802**
B. Albert, J. Gürtler, R. Emmerling, L. Hüneke, C. Kühn, G. Thaller, J. Bennewitz, C. Schmidtmann

High-Sensitivity Detection of Genome-Edited Pigs and Cattle by CAST-PCR **803**
F. Poulain, M. Dias Mirandela, F. Debode, V. Gelhay, C. Muys, B. Renaville

Genetic investigation of the boar taint compounds androstenone and skatole using SNP chip data and whole genome sequencing data in dam lines **804**
K. M. Flüchten, I. Brinke, C. Große-Brinkhaus, M. J. Pröll-Cornelissen, H. Henne, E. Tholen, C. M. Dauben

How Pure is Pure Breeding? A Case Study of a commercial German pig breed **805**
L. Kistner, A. Olschewsky, L. Vollmer, C. Reimer, D. Hinrichs

Local ancestry aware genome-wide association study of dairy traits using both purebred and crossbred data **806**
B. Poulsen, H. Liu, E. Karaman

Genetic Markers Associated with Slaughter Yield in Intensively Fattened Lambs Raised in Latvia **807**
E. Leonova, M. Martins, D. Malakovska, S. Plavina, N. Krasnevska, J. Paramonovs, D. Kairisa, N. Paramonova, I. Trapina

Semen Cryopreservation as a Conservation Strategy for the Native Species Salmo ghigii in Sardinia: Results on Fertilization and Embryonic Development **808**
F. Chessa, F. Curreli, L. Mara, I. Cossu, A. Sabattini, P. Casula

Characterization of Missense Mutations in Acute Phase Proteins in a Cellular Model for Chicken Amyloid Arthropathy **809**
N. F. Paul, E. Maier, J. Tetens, C. Falker-Gieske

De-novo assembly of a high-quality, haplotype-resolved genome assembly for the Ugandan Ankole cattle **810**
R. Okwasiimire, M. Weldenegodguad, M. Makgahlela, N. Ghanem, C. Ginja, R. Crooijmans, D. Kugonza, J. Kantanen, K. Pokharel, P. Uimari

Influence of genetics and rumen microbiome on bovine milk vitamin B2 and B12 **811**
A. J. Buitenhuis, L. E. Rodrigues, N. A. Poulsen, C. W. Heegaard, G. Gebreyesus

Near teleomere-to-telomere assemblies of Swedish commercial dairy cattle breeds, Swedish red- and white, Holstein and Jersey **812**
A. E. Lundberg, T. Vanhala, T. Klingström

Accuracy of Genomically Enhanced Breeding Values in South African Holstein Cattle for Milk Production Traits **813**
K. Mafolo, F. Neser, E. Cason, D. Vermeulen, M. Macneil, M. Makgahlela

Comparison of genomic evaluation models on simulated crossbred dairy cattle populations **814**
C. A. Cunha Cambraia, P. Croiseau, D. Boichard, S. Fritz, A. A. Martin

Unknown Parent Groups in Turkish Holsteins: Metafounders Approach **815**
A. Kasakolu, M. Yıldırır, O. Yiğit, F. G. Mızrak, E. Ünay, S. Koncagül

Session 46. 'How does the diversity of European cattle and poultry livestock systems influence the quality of meat and milk, and the sustainability of farms?' Key outcomes from the European INTAQT project

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Martin, Berri - Commission(s): C, PO, P, LFS - Session Type: Project session

Theatre Session 46

Combining sustainable poultry farming and meat quality: Insights from the intaqt project **816**
C. Berri, L. Darrigade, M. Bourin, E. Baéza, R. Eppenstein, M. Petracci, S. De Smet

Nutritional outcomes of high-intensity broiler farming with regard to amino acid patterns and protein digestion efficiency **817**
V. Santé-Lhoutellier, L. Aubry, C. Selebran, V. Lopez, V. Lopez, L. Darrigade, S. De Smet, M. Petracci, R. Eppenstein, A. Travel, C. Berri

Effect of outdoor enrichment and dietary supplementation with n-3 fatty acid precursors and antioxidants on meat quality of free-range chickens **818**
M. Bordini, A. Cartoni Mancinelli, E. L. Antenucci, M. A. Gagliano, F. Soglia, A. Dal Bosco, M. Petracci

Identifying farming practices associated with beef fatty acids, trace minerals and antioxidants across European production systems **819**
A. Mouhanna, J. Hocquette, B. Martin, N. Amalfitano, R. Eppenstein, N. Scollan, M. Estévez, I. Legrand, S. De Smet

Occurrence of persistent organic pollutants, mycotoxins and heavy metals in liver of beef in different farming systems **820**
D. Linsler, C. Kürbis, A. Lueth, M. Yamamoto, R. Pieper, J. F. Hocquette, R. Eppenstein, B. Martin, L. Darrigarde, M. Estévez Garcia, V. Caballero Fernández, P. Mccarron, F. Klevenhusen

Linking dairy system, breed, and welfare indicators to infrared-predicted fine milk composition and cheese-making traits in Parmigiano Reggiano cheese production area **821**
N. Amalfitano, M. A. Ramirez Mauricio, M. Berton, D. Giannuzzi, L. F. Macedo Mota, M. Nocetti, S. Pegolo, L. Gallo, E. Sturaro, A. Cecchinato

A harmonized methodological framework for multi-criteria assessment of intrinsic quality in EU livestock products **822**
L. Rey-Cadilhac, J. Soulat, F. Klevenhusen, J. F. Hocquette, C. Berri, B. Martin, V. Monteils, C. Laurent

Number of animal lives vs. quality of life in broiler, dairy, and beef production **823**
E. Caumette, B. Martin, C. Berri, R. Eppenstein, I. Veissier

Milk mid-infrared spectra potentially authenticates farming system intensification level and season of production **824**
C. L. Manuelian, D. Martini, A. Goi, M. Coppa, E. Caumette, C. Grelet, R. Eppenstein, M. Gelé, B. Martin, M. De Marchi

Infrared spectroscopy for farming system classification and beef quality assessment: a multi device chemometric approach **825**
A. Lopez, B. Martin, J. F. Hocquette, I. Constant, O. Joubert, V. M. Moretti, D. Andueza

Poster Session 46

Evaluating the Impact of Traditional Montanera vs. Intensive Feeding Systems on Technological Meat Properties in Iberian Pigs: Implications for System Resilience **826**
M. Freire, J. Garcia-Gudiño, A. Ortíz, L. León, A. I. Del Rosario, D. Tejerina

Factors influencing the phospholipid profile and concentration in cow milk: A study in commercial European dairy farms varying in intensification level **827**
V. Menoury, B. Martin, L. Rey-Cadilhac, A. Ferlay

Session 47. Animal microbiomes - moving forward from taxonomic to functional information - in conjunction with the Horizon 2020 Holoruminant project - Part 1

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Seifert, Kenny - Commission(s): PH - Session Type: Theme session

Theatre Session 47

Early-life antimicrobial treatment have long-term effects on the fecal microbiota of dairy calves **828**
A. Ortiz Chura, M. Popova, A. Bachelet, D. P. Morgavi

The effect of transitioning from low energy to high energy diets, and vice versa, on viruses and their hosts in the rumen fluid and faeces of Holstein dairy cows **829**
D. A. Linde, J. S. Saenz, M. Bakiasi, J. Seifert

Metaproteomic Insights into Energy-Driven Microbial and Protozoal Functional Shifts Across the Ruminant Gastrointestinal Tract **830**
M. Bakiasi, J. S. Saenz, J. Seifert

Plasma Extracellular Vesicle Proteomics Reveals Systemic Metabolic Adaptation to Dietary Energy Transition in Dairy Cows **831**
A. Malik, M. H. Ghaffari, N. Ranjbar, F. Shakeri, A. Buness, M. Sylvester, H. Sauerwein

Industry-level value and welfare consequences of methane-reducing feed additives in EU ruminant value chains **832**
A. Ait-Sidhoum, F. Bedoin, J. K. Niemi

Enabling Methane Mitigation with Standardized Rumen Microbiome References and Pipelines **833**
Z. Cai, M. A. Satti, M. Maigaard, I. Farhana, S. Zhang, T. D. E. Rozada, A. Schönherz, S. J. Noel, M. R. Weisbjerg, G. Sahana

Response of primary mammary epithelial cells to pathogen challenge in dairy cows **834**
T. Iso-Touru, F. Panitz, D. Fischer, S. Taponen, Z. Cai, G. Sahana, K. Kondrotienė, M. Malakauskas, I. Tapio, J. Vilkki

Mapping Tryptophan-Derived Metabolites along the Bovine Small Intestinal Tract: An Evolutionarily Distinct Host–Microbiota Adaptation in Ruminants? **835**
A. Veshkini, S. Bes, J. Tournayre, A. Imbert, M. Bonnet

Deciphering the Bovine Nasal Microbiome by reconciling 16S rRNA sequencing and culturomics **836**
S. Méndez Barroso, G. Pot, M. Monié-Ibanes, H. Robert, D. Bars-Cortina, X. Laurent Nouvel, C. Citti, K. Kochanowski, N. Mach

Dietary supplementation with buffer and protected amino acids improves milk production and modulates microbiota in heat-stressed primiparous dairy goats **837**
E. Romera-Recio, E. Ramos, M. Romero-Huelva, I. Rivelli, J. Barroso, A. Gomez-Mesonero, D. R. Yanez-Ruiz

Poster Session 47

Exploring Bacterial Defluorination of Sodium Fluoroacetate in Rumen Fluid **838**
E. D. Cason, R. Kaputjaza, G. C. Josling, J. B. Van Wyk, P. D. Vermeulen, F. W. C. Neser

Influence of post-birth management and milk replacer feeding level on early life performance, health and behaviour of dairy calves **839**
G. Scoley, K. Lawther, S. Huws, C. Ferris

Is the Pig Faecal Microbiota Shaped by Host Genetics? **840**
C. Engelking, A. Camarinha-Silva, M. Rodehutscord, J. Bennewitz, V. P. Haas

Comprehensive analysis of rumen-derived bacteriocin-producing Lactococcus lactis for Streptococcus biofilm control strategies **841**
A. Elnar, M. A. Batican, J. Jeong, G. Kim, R. Kang, T. Park

Session 48. Unravelling the next generation animal nutrition: functional feed ingredients and additives - Part 2

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Alvarez-Rodriguez, Kar, Foggi - Commission(s): N - Session Type: Theme session

Theatre Session 48

Effects of selected rapeseed meal cultivars in low-protein diets on performance and oxidative stress in dairy cows and their calves during the periparturient period **842**
S. Lemosquet, H. Quesnel, Y. Le Cozler, B. Graulet, J. C. Martin, F. Gondret

Supplementing a Bacillus-based probiotic to mitigate acidosis in beef cattle consuming a high-concentrate diet **843**
R. Cooke, B. Cappellozza

Effects of inoculation of corn silage with Lactobacillus buchneri and Lactococcus lactis on silage quality and stability, and production performance and efficiency in beef cattle **844**
S. Grossi, C. A. Sgoifo Rossi

Effects of Biochar Supplementation on Milk Yield, Milk Composition, Milk Fatty Acids and Health in Dairy Cows **845**
A. N. Rückert, D. Dannenberger, A. Eggert, M. Oster, H. Reyer, A. Vernunft

Effects of supplementing 25 OH vitamin D3 on immune markers and colostrum quality in Holstein cows during the transition period, and on plasma vitamins and metabolites in their newborn calves **846**
S. Lashkari, M. Vestergaard, N. B. Kristensen, T. D. Turner, S. K. Jensen

Effects of a rumen-protected choline prototype on milk yield and composition, liver triglyceride, and blood parameters for early lactation Holstein cows exposed to feed restriction **847**
C. Bradford, N. Hogan, T. Mutsvangwa, G. Penner

Breed impacts voluntary intake of hydroxychloride and sulphate sources of trace minerals in beef heifers **848**
D. Brito De Araujo, K. V. Z. Augusto, M. A. F. Porcionato, J. L. M. Vasconcelos, P. Moriel

Post-weaning optimization by using fibrous concentrate and essential oils supplementation in lambs **849**
A. H. Chekikene, J. Muñoz-Grein, N. Ghallabi, A. Belanche

Effects of oilseed supplementation on organoleptic and nutritional quality of Rubia Gallega veal **850**
C. Montes, S. Crecente, C. García, R. Alonso, T. Moreno

Immune-activating PhytoComplex solution reduces cryptosporidiosis severity in neonatal calves through Interleukin-18–mediated host defense **851**
M. De Kock, Y. Han, E. H. Wall, M. M. Mia, A. R. Azam, W. H. Witola

Poster Session 48

Supplementing a Bacillus-based probiotic to mitigate frothy bloat in beef cattle receiving a high-concentrate diet **852**
R. Cooke, B. Cappellozza

Effects of vitamin D_3 on cell viability, myogenic regulatory factors, and antioxidant responses in bovine skeletal muscle cells under heat stress **853**
J. H. Lee, X. C. Jin, B. M. Kim, H. J. Oh, J. S. Lee, H. G. Lee

Targeted cis-9, trans-11 CLA bioconversion in in vitro rumen fermentation catalyzed by Bifidobacterium-based probiotic and postbiotic supplementation **854**
A. Elnar, J. Jeong, G. Kim, R. Kang, G. B. Kim, T. Park

The effect of lowering the crude protein of dairy diets with the addition of either a molasses based liquid feed (Regumix) alone or with Regumix + methionine supplementation on production performance and efficiency **855**
G. Chapman, P. Holder

Dietary Polyphenols Modulate Milk Production and Udder Inflammation in Commercial Dairy Herds **856**
G. H. M. Marcelino, W. V. B. Soares, B. Hortolani, L. C. Roma Junior

Effect of a phytogenic ingredient mixture on rumen degradability of soybean meal protein **857**
F. Gadeyne, J. Jeyanathan, V. Fievez

Optimizing amino acid supply in early lactation cows improves production performance in commercial farm conditions **858**
A. Vigh, M. Müller, J. Guyader

Microalgae supplementation enhances omega-3 PUFA in lamb meat and its consumption improves blood fatty acid status in consumers **859**
L. Perkins, O. Cristobal Carballo, F. Godoy Santos, S. Morrison, A. Aubry, E. Lewis, T. Yan, N. Scollan, S. Huws

Session 49. The role of intrinsic and extrinsic quality in beef industry

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Pethick, De Marchi, Singh - Commission(s): C - Session Type: Theme session

Theatre Session 49

Grape pomace silage in the finishing diet of beef steers **860**
L. Forte, M. Santoro, G. Calzaretti, F. Rosalia, R. Roma, P. De Palo, A. Maggiolino

Multivariate relationships between carcass, muscle, and beef eating quality traits in Limousine cull cows **861**
Y. Cui, A. Neveu, M. Kombolo, J. Liu, I. Legrand, F. Noel, P. Faure, D. Pethick, M. P. Ellies-Oury, J. F. Hocquette

The effect of post-slaughter time on marbling scores in beef carcasses **862**
H. Shand, S. Connaughton, G. Gardner

Physicochemical quality differentiation of European beef cuts by retail price category, sex, and region reared **863**
Y. Singh, M. Pozza, D. Martini, M. De Marchi

REIMS-based metabolic fingerprinting discriminates animal categories across muscle types, and ageing regimes in beef loin **864**
Y. Cui, A. B. Ross, C. Realin, R. Zhang, D. Mou, V. Ruppert, J. F. Hocquette

Growth performance in Chianina cattle: a 10-year database comparison between PGI production scheme and EU mandatory beef labelling system **865**
A. Fioroni, L. Seri, R. Fioroni, V. Bolletta, M. Pauselli

When beef turns brown: a cross-country comparison of consumer preferences in Germany and USA **866**
B. A. Altmann, E. López-Escalante, A. Thies, N. Kemper, M. N. Nair

Can bone mineral density by dual-energy X-ray absorptiometry predict age, shear force, and collagen in cull cows' carcasses? **867**
P. G. Vilas Boas, S. L. Connaughton, C. L. C. Nunes, L. K. E. S. Jesus, G. E. Gardner, M. L. Chizzotti

Effect of breed and post-mortem aging time on beef eating quality assessed by untrained Brazilian consumers **868**
N. Mendes, W. Baldassini, M. Coutinho, G. Rovadoscki, T. Oliveira, L. Chardulo, J. F. Hocquette

Bovine appeasing substances before and after transport reduce beef stress **869**
M. D. M. Campo, J. Vieira Romero, N. Huanca Marca, G. Miranda De La Lama

Poster Session 49

Authentication of dry and wet aging in Angus beef steaks by means of near-infrared spectroscopy **870**
L. León, A. Ortiz, M. Freire, D. Tejerina

Evaluation of texture in dry- and wet-aged beef at different pH under various packaging: a preliminary assessment **871**
J. V. Romero, M. P. Lierta, J. L. Olleta, M. Bueno, M. M. Campo

Incorporating dry-aged beef crust into burger patties: evolution of quality traits over a 7-day retail display **872**
Y. Singh, M. Tóth, S. Sabbadin, D. Martini, M. Pozza, R. De Lazzari, M. De Marchi

Delivering consistent beef eating quality in Poland: consumer sensory testing supporting the QMP scheme **873**
A. Neveu, G. Pogorzelski, R. Polkinghorne, H. Cuthbertson, E. Pogorzelska-Nowicka, J. Wierzbicki

Sensory quality and fatty acid composition of beef from Holstein–Friesian bulls finished with different protein sources **874**
Z. Nogalski, M. Momot

Predicting beef eating quality: Evaluation by INRAE of an innovative approach to align with consumer and stakeholder expectations **875**
J. F. Hocquette, I. Legrand, A. Neveu, M. P. Ellies-Oury, S. Chriki, D. Troy, V. Molinéro-Demilly, F. Gaymard, R. Polkinghorne

Session 50. Innovating Together: participatory, pluridisciplinary and multi-level approaches to livestock systems and agroecological transition

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Siqueira, Morgan, Thenard - Commission(s): LFS - Session Type: Theme session

Theatre Session 50

Participatory and iterative approach to design collective strategies of crop-livestock integration **876**
F. Stark, M. Moraine, M. Grillot, J. Ryschavy

Livestock system transformation as a societal task: governance lessons from a stalled multi-stakeholder strategy in Germany **877**
B. Grabkowsky, N. Zubek, T. Blaha

A Biocultural Diversity Index for Assessing Animal Husbandry Sustainability **878**
B. A. Altmann, C. Heindorf, L. Jung, N. Kemper, E. Varela

Multicriteria evaluation of mixed sheep-beef production systems **879**
P. Madrange, L. Thuault, M. Velghe, S. Passerieux, M. Miquel

Network Focus Animal Welfare – how to transfer practice-orientated knowledge into practice **880**
K. Brase, C. Lambertz

How do livestock farming system issues come into play in the design of breeding programs for agroecology? Key points from researchers'narratives of their experiences in a transdisciplinary project **881**
P. Coeugnet, N. Bedere, J. Labatut, F. Phocas, G. Restoux, M. Tixier Boichard, A. Lauvie

Co-designing climate adaptation strategies in PDO/PGI livestock territories: a typology of participatory and multi-level approaches from the ADAoPT project **882**
D. Neumeister, F. Bedoin, R. Lasbleiz, S. Dernat

Lessons learned from living labs on Swiss and Italian beef production in the Project "INnovative Tools for Assessment and Authentication of chicken meat, beef and dairy products' QualiTies" **883**
R. Eppenstein, E. Sturaro

SPICER^2 : a multi-partners network to promote the improvment of Cultures-Livestock Interactions in the French agriculture **884**
P. Mischler, G. Martel, M. Moraine, V. Thenard, S. Ramonteu, S. Pissonier, C. Gava, S. Bruley, E. Merot

Poster Session 50

Enhancing interoperability through transparent multidirectional data architecture for individual animal data valorization in the pig value chain **885**
S. Retz, D. Moerlein, Y. Chen, Z. Bodor, F. Heinrich, A. Schmitt, H. Grevemeyer, V. Beck, S. Fischer, R. Hoelscher

Supporting Farmers in Developing Systems with Higher Human-Edible Protein Output: Balancing Animal and Crop Production at Farm Level **886**
B. Genin, M. Fazzari, P. Aeby, E. Ollion, P. Rufer, P. Veysset, B. Reidy

Understanding drivers and barriers for implementing grassland and feeding measures to reduce ammonia and methane emissions in Dutch dairy farming **887**
A. Van Den Pol-Van Dasselaar, W. Van De Geest

Integrated assessment of sustainability indicators in pasture-based and intensive dairy sheep systems in Central Italy **888**
A. Iannetta, M. Dos Santos Lima, L. Torricella, L. Baldacchini, C. Cimini, L. Iannetti, G. Vignola, A. Collin, M. Podaliri Vulpiani

Session 51. Efficiency and mitigating emissions in pig production – strategies to reduce nitrogen and phosphorus losses, including amino acid nutrition - Part 1

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Girard, Lawlor, Chalvon Demersay - Commission(s): P, N - Session Type: Theme session

Theatre Session 51

Evaluation of animal-level strategies for reducing nitrogen and phosphorus losses and their effectiveness in mitigating the environmental burden of pig production **889**
F. Garcia-Launay, L. Cappelaere, F. De Quelen, P. Lin, P. Schlegel, R. Aklikokou, M. P. Létourneau Montminy

Variation in N and P excretion from sows, weaners and grower-finisher pigs **890**
A. L. F. Hellwing, P. Tybirk, S. S. Grove, P. Kai, C. F. Børsting

Continuous monitoring of ammonia emissions in a fully slatted, mechanically ventilated commercial finishing pig facility, Ireland **891**
I. M. Aroh, G. Mccutcheon, D. Krol, R. Kuneš, S. Conolly, E. G. Manzanilla, T. Curran, L. Clarke

Integrated nutritional and housing strategies to improve nitrogen utilization efficiency and mitigate ammonia emissions in pig production **892**
E. Nnando, C. Anozie, E. Aidelomon

Low-protein diets with graded essential amino acid supplementation as a strategy to improve nitrogen utilisation and reduce ammonia production in growing-finishing pigs reared under contrasting hygienic conditions **893**
A. Antonacci, P. Silacci, G. Bee

A controlled medium scale open circuit chamber approach to quantify the effect of crude protein and lysine supply on nitrogen efficiency and ammonia emissions in pigs **894**
S. Goethals, T. Van De Gucht, N. Peiren, P. Bikker, A. J. Jansman, S. Millet

Effects of dietary lysine supply on nitrogen utilisation in organic growing–finishing pigs **895**
L. Stødkilde, T. F. Pedersen, E. T. Jørgensen, M. Eskildsen

Evaluating the Role of Dietary Silicate (SiO_3) and Zinc Oxide on Growth Performance, Nutrient Utilization, Gas Emission, Blood parameter and Environmental Impact in Weaning Pigs **896**
K. Das, S. Y. Jang, L. Pu, D. K. Kang, I. H. Kim

Reducing environmental nitrogen losses through improved nitrogen retention in weaned piglets fed humic acids **897**
S. Rongen, I. Van Den Belt, A. Van Enckevort, I. Van As

Poster Session 51

Relationship between nitrogen and phosphorus intake during pig fattening and the CO_2 footprint per kilogram of live weight. **898**
S. Rosengart, C. Timme, S. Büngener-Schröder, K. Sehlen, J. Gickel, C. Visscher

Feeding the balance: how diet optimisation goals affect nitrogen and phosphorus inputs and outputs in Swiss grower-finisher pigs **899**
M. Girard, M. Lautrou, P. Schlegel

Impact of swine influenza on greenhouse gas (GHG) emissions on Japanese commercial farms **900**
S. Yoshikawa, A. Ogino, J. Mine, K. Miyazawa, Y. Uchida, Y. Mizoguchi, Y. Sasaki

Evaluation on low crude protein diet with protease supplementation on growth performance, fecal score, backfat thickness and lean meat percentage, nutrient digestibility, meat quality, and carcass grade in finishing pigs **901**
K. J. Lee, C. C. Henry, K. Das, D. K. Kang, I. H. Kim

Effects of dietary silicate supplementation with varying levels of proteins on growth performance, nutrient digestibility, gas emission, blood profile and fecal score in weaning pigs **902**
S. Y. Jang, K. Das, J. H. Kim, K. Han, I. H. Kim

Individual and Combined Supplementation of Microbial Phytase and β-Mannanase in Growing Pigs: Impacts on Growth Performance, Nutrient Digestibility, and Fecal Scores **903**
S. Y. Jang, W. Zhao, L. Pu, D. K. Kang, I. H. Kim

Session 52. Assessing Animal Welfare: Protocols, Indicators and Emerging Approaches

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Trocino, Almeida - Commission(s): HW, SG, P, G - Session Type: Challenge session

Theatre Session 52

Feasibility and repeatability of standard protocol to assess animal welfare **904**
O. Girardie, A. Velarde, J. Zemzmi, M. Campoy, L. Baldacchini, M. Milazzo, L. J. Vinco, S. Podda, V. Monistero, C. Tolini, A. Trocino, S. Celozzi, M. Guinebretière, V. Michel

Animal Welfare Index – A new on-farm welfare assessment method **905**
D. Debiasi, S. Götz, U. Höne, J. Krieter, J. Probst, N. Kemper, S. Küster, I. Reker, G. Otto, I. Traulsen

New welfare assessment protocol for dairy cattle herds **906**
L. Frondelius, M. Mughal, L. Tuomisto, K. Sarjokari, T. Koistinen

Potential of barn climate parameters as iceberg indicators in welfare assessment and their relationships with productivity in fattening pigs **907**
N. Puttkammer, J. Witt, K. Büttner, J. Krieter, P. Sandøe, I. Czycholl

Effect of dehorning on salivary cortisol responses in South African Bonsmara beef calves **908**
R. Erasmus, M. Combrink, C. Uys, S. Lashmar, E. Van Marle-Köster

Circulating MiRNAs as Potential Biomarkers Of Pain And Stress in Piglets Undergoing Castration **909**
E. Nadlučnik, M. Arigoni, R. Calogero, M. Štukelj, C. Lecchi

Effect of plumage condition on the welfare of end-of-lay broiler breeders exposed to a transport model **910**
J. Verlaat, E. M. Leishman, C. J. A. Williams, M. S. Herskin, A. B. Riber

Poster Session 52

Indicators for assessment of animal welfare on euthanized or deceased animals **911**
C. Over, B. Prottengeier, R. Magner, S. Schlierenkamp, U. Schultheiß

Field Feasibility and Repeatability of Standardised Protocols for Turkey Welfare Assessment **912**
V. Monistero, S. Podda, O. Girardie, V. Michel, A. Velarde, N. Abdelli, J. Zemzmi, S. Celozzi, V. Ferrante, L. J. Vinco

Animal welfare in pork production: Farmer and Veterinarian perspectives **913**
M. E. Lagoda, K. A. Moak, K. Arisman, M. Kaczur, T. L. Sandri, N. Wuyts, L. Van De Weyer, Y. M. Seddon

Harmonization and Standardization of Indicators for Assessing Sheep Welfare **914**
M. Milazzo, C. Cimini, L. Baldacchini, D. Hazard, N. Abdelli, D. R. Arney, F. Johansen, J. Zemzmi, O. Girardie, G. E. Martin Valls, V. Michel, M. Podaliri Vulpiani, A. Velarde, L. Iannetti, S. Mullan

Sensor-based monitoring of behavioural adaptation of dairy calves during regrouping from individual or social housing to group housing **915**
J. M. Chapa Gonzalez, J. Sonntag, S. Wiedemann

On-farm self-assessment – tools to improve cattle welfare **916**
J. Brinkmann, K. Cimer, S. March, S. Ivemeyer, A. Pelzer, U. Schultheiß, R. Zapf, C. Winckler

Promoting Cattle Welfare Planning **917**
U. Peschel, J. Brinkmann, S. March

Session 53. The EUnetHorse project: results and new research perspectives

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Vial, Mathieu

Theatre Session 53

From Knowledge to Practice: Ensuring Long-Term Impact in the European Equine Sector through EUnetHorse and TANet **918**
N. Aldai, E. Martínez-Monasterio, S. Vilumbrales, S. Kuhnke, A. Julien, M. Addes, E. C. Eunethorse Consortium

Improving resilience of equine farms: EUnetHorse's methodology for assessment of solutions and best practices in the areas of animal welfare, socio-economics and environmental sustainability **919**
U. König Von Borstel, S. Lojewski, L. Rantamäki-Lahtinen, E. U. Eunethorse Consortium, M. Addes

EUnetHorse : Recognising the equine sector : unlocking its contribution to Europe's climate, rural and competitiveness goals **920**
M. Addes, A. Julien, M. Rinne, L. Tourneur, A. Santos, N. Aldai

Group discussion Part 1 **921**
M. Addes, C. Vial, G. Mathieu

Group discussion Part 2 **922**
M. Addes, C. Vial, G. Mathieu

Session 54. Towards smart livestock systems: next-generation PLF technologies and sound-based monitoring

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Lebreton, Maroto Molina, Foy, Volkmann - Commission(s): PLF - Session Type: Theme session

Theatre Session 54

Thematic expert panel insights on state-of-the-art digital tools and technologies in the livestock sector **923**
S. Vouraki, V. Anestis, A. Arsenos, G. Arsenos, T. Bartzanas

UHF RFID technology in livestock applications: synthesis of French case studies in the ruminant sector over 10 years **924**
S. Duroy, G. Tesnière, U. Jean-Louis, L. Depuille-Plais, P. G. Grisot, F. Gimbert, C. Medina, F. Dehmas, N. Deparis, D. Gautier, C. Allain

Machine Learning models for Auto-Annotation of Behavioral Data to Generate Digital Ethograms **925**
D. Foy, T. Smith, J. Reynolds, T. Parsons

Individual fattening pig growth profile estimation **926**
J. Slootmans, T. Norton, J. Maselyne

Risk Factors for Piglet Preweaning Mortality in Spanish Breeding Farms. Preliminary Results from the Bdporc-Smartporc Project **927**
S. Rani, A. Arrazola, M. Pascual, N. Alos, M. Visa, M. Piles, R. Quintanilla, J. Tarres, L. Tusell

Drone-based mapping of geese range use under heat across pasture systems: implications for silvopastoral agroforestry design **928**
J. Menne, S. Eßer, P. Eßer, S. Wiedemann

An introduction to bioacoustics with a focus on chicken vocal responses to birds of prey **929**
A. Langehennig-Peristenidou, L. Hofmann, N. Kemper, N. Volkmann

Eyes & Ears – the auditory perspective: evaluating the potential of sound-based monitoring for livestock health, behaviour and welfare **930**
M. Coutant, S. Ntalampiras, W. Wang, P. Llonch, E. Mainau, M. Van Der Sluis, L. Büttgen, C. Gaillard, L. Canario, T. B. Rodenburg

Development of a Practical Benchmark for Pig Vocalizations in Noisy Farm Environments **931**
M. Wutke, H. Geffert, S. Geisler, S. Küster, C. Post, J. Wahmhoff, I. Reker, I. Traulsen

Poster Session 54

Efficient Bioacoustic Classification of Goat Vocalizations for Edge-Based Precision Livestock Farming **932**
D. A. Mendez Reyes, S. Calvet Sanz

Sound levels during unloading, in lairage and in the stunning area in cattle slaughterhouses **933**
S. Lühken, C. Nyanzi, K. Kauselmann, L. Schrader

Relationship between claw health and increased activity during milking as a supportive trait for lameness detection in dairy cows **934**
P. Savary, D. Schönberger, M. Bodmer

Image-based classification of horned and polled Caracu cattle using machine learning **935**
G. Fernandes, V. Weber, V. Ligori, L. Pereira, D. Lisboa, G. Borges, L. El Faro

Benchmarking pig detection and tracking under diverse and challenging conditions **936**
J. Henrich, C. Post, M. Zilke, P. Shiroya, E. Chanut, A. Mollazadeh Yamchi, R. Yahyapour, T. Kneib, I. Traulsen

Automated Sorting of Finishing Pigs Under Commercial Barn Conditions **937**
M. Tufail, N. Yeo, T. Tayenga

Session 55. Digitalization, artificial intelligence and Precision Livestock Farming (PLF) in Small Ruminants: From Sensors to Decision Support.

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Emsen, Karatzia - Commission(s): SG, PLF - Session Type: Theme session

Theatre Session 55

From counting small ruminants with drones and AI to future applications enabled by offered open data and computer vision models **938**
A. Lebreton, T. Dechaux, E. Nicolas, P. G. Grisot, L. Helary

Feasibility of Pulse Oximetry and Infrared Thermometry for Monitoring Vital Signs in Dairy Goats **939**
J. Muñoz-Quirós, B. Sosa-Marrero, M. González-Cabrera, A. Morales-Delanuez, A. Argüello, N. Castro, L. E. Hernández-Castellano

Effect of Heat Stress on Heart Rate Variability in Dairy Sheep at Pasture Using a Smartex Textile Sensor **940**
L. Turini, L. Whatford, G. Foggi, A. Mantino, F. G. Cella, T. Malizzi, M. Mele

Accelerometer-based behavioural classification in grazing alpacas in the Andes: effects of sensor location and temporal window length **941**
K. Salazar-Cubillas, S. Pizarro Carcausto, M. Zarria Samanamud, J. L. Contreras Paco

Lambing Detection in East-Friesian Dairy Sheep Using Pen-Level Acoustic Monitoring **942**
N. Westendorff, B. Puppe, B. Eusemann-Keller, K. Helffenstein, B. Kuhla, C. Manteuffel

Prediction of milk metabolites from mid-infrared spectra and estimation of genetic parameters in dairy goats **943**
C. Brosse, M. Calmels, M. Bonnet, N. Friggens, T. Fassier, J. Pires, R. Rupp

A Multi-Stage, Data-Driven Welfare Assessment Framework for Small Ruminants under Intensive Feedlot Conditions in a Hot-Arid Environment **944**
E. Emsen, B. Odevci, A. Alkaabi, D. Alketbi, M. Kutluca Korkmaz

Artificial neural networks outperform partial least squares models for fatty acids estimation using FT-MIR spectrometry on bovine milk: a first step towards transfer learning on small ruminants. **945**
E. Cabaraux, I. Alexakis, F. Sébastien, O. Christophe, C. Grelet, M. Calmels, C. Lecomte, C. Bertozzi, D. Veselko, F. Dehareng, H. Soyeurt

Early-life milk intake and drinking behaviour as predictors of growth and first-lactation performance in dairy goats **946**
J. Caetano De Sousa, J. F. Ettema

Poster Session 55

SNP-guided prediction of feed conversion ratio in Latvian sheep: machine learning models for marker-assisted selection. **947**
M. Martins, N. Paramonova, S. Plavina, D. Malakovska, N. Krasnevska, J. Paramonovs, D. Kairisa, I. Trapina

Exploring a data-driven approach to evaluate general resilience in lambs through cumulative feed intake **948**
F. Barchet, A. Oliveira Rocha, G. Ciappesoni, M. S. Aktar, L. F. Brito, I. De Barbieri

Combining multi-sensor data and machine learning for automated behaviour classification and disturbance detection in sheep **949**
S. Gerwin, J. Henke-Von Der Malsburg, A. Vernunft

Assessment of Optimum Drying-Off model on Milk Yield in Assaf Ewes **950**
I. Contreras-Solís, D. López-Carbonell, C. Palacios, J. A. Abecia

Session 56. Optimal and sustainable insect production

Date: Wednesday 9 September 2026; 8:30 - 11:30
Chair(s): Bellezza Oddon, Ottoboni, Veldkamp, Coudron - Commission(s): I - Session Type: Theme session

Theatre Session 56

Mineral requirements of Tenebrio molitor larvae: magnesium, potassium and phosphorus needs **951**
A. Moradei, P. Premarajan, M. Ottoboni, L. Pinotti, T. Spranghers

Effects of structural fibre ingredients on black soldier fly (Hermetia illucens L.) larval growth at industrial and laboratory scales **952**
S. Naser El Deen, E. De Lange, L. Francuski, S. Karanjit, T. Veldkamp

Protein-to-soluble carbohydrate ratio in the diet for Tenebrio molitor imagoes modifies their reproduction, egg viability and young mealworm survival **953**
T. Añón, M. Cambra-López, J. Just, J. J. Pascual

The effect of tomato leaf waste handling on the growth performance, nutritional composition, and glycoalkaloids content in the desert locust Schistocerca gregaria **954**
Y. Luo, N. Förster, M. Bogdanova, S. Schulz, I. Mewis, C. Ulrichs, W. Yakti

From olive waste to insect biomass: evaluating increasing levels of olive pomace in black soldier fly production **955**
R. Sorayani Bafqi, S. Bellezza Oddon, A. A. Melis, Z. Loiotine, I. Biasato, R. L. Passaro, L. Gasco

Integrating Insect Production Into Greenhouse Systems: Using Tomato Leaf Biomass as Insect Feed **956**
W. Yakti, Y. Luo, S. Bisch-Knaden, I. Mewis, C. Ulrichs

Turning Waste into Value: Effects of olive fragments on Black Soldier Fly Larvae Performance **957**
T. Gogou, R. Nakirya, P. Soulioti, E. Valli, C. Rumbos, M. Capucchio, C. Athanassiou

Valorizing Apple and Olive Pomaces: How Density and Substrate Shape Hermetia illucens Larval Performance **958**
P. Soulioti, T. I. Gogou, R. H. Nakirya, E. Valli, C. I. Rumbos, M. T. Capucchio, C. G. Athanassiou

Poster Session 56

The effect of the growth substrate on the content of essential amino acids in Hermetia illucens larvae **959**
M. Matvieiev, V. Dzhus, I. Doroshenko, O. Borshch, V. Lykhach, A. Getya

Dietary fat sources modulate growth performance and lipid composition of black soldier fly (Hermetia illucens) larvae **960**
L. Schneider, N. Stoehr, G. Dusel

Trentinsect: insects and sustainability in feed production **961**
A. Resconi, M. Baker Ala Eddine, G. Benassi, S. Dabbou

Use of ergot (Claviceps purpurea) - contaminated rye in the rearing of black soldier fly (Hermetia illucens) larvae **962**
N. Stöhr, L. Schneider, K. Schuh -Von Graevenitz, W. Markert, T. Priesmann, G. Dusel

Session 57. Optimizing inclusion of novel traits into existing breeding goals

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Kargo, Strucken - Commission(s): G - Session Type: Theme session

Theatre Session 57

Methodological approach for multi-trait information pooling into single-trait using deregression: a study case on boar taint **963**
A. Markey, N. Gengler

Selection for birth weight uniformity and its effects on subsequent weights in SRC Iberian pigs **964**
I. Cervantes, N. Formoso-Rafferty, F. Sánchez-Esquiliche, L. Ramírez, M. Muñoz, J. M. García-Casco, J. P. Gutiérrez

Potential to increase additive genetic variance in pigs by changing crossover count **965**
O. Katz, Y. C. J. Wientjes, A. C. M. Jansen, M. P. L. Calus

Heritability and Genetic Correlations of Crossover Count in Two Commercial Pig Lines **966**
A. C. Jansen, O. Katz, M. P. Calus, T. Druet, A. Boshove, Y. C. Wientjes

Methods for joint genetic prediction of multiple ordinal categorical and continuous traits **967**
M. Bermann, A. Legarra, A. Alvarez Munera, I. Misztal, D. Lourenco

xyBnG.jl: A Julia package for scalable, GPU-accelerated stochastic simulation of complex national livestock breeding schemes **968**
X. Yu, L. Cao, J. Jakobsen, G. Difford, P. Berg, B. Åby

EVOGEN: A novel tool for large-scale simulation and optimization of breeding programs **969**
V. Milkevych, A. Bouquet, H. Liu, B. Grove Poulsen, M. Sandø Lund

Beekeepers' preferences for breeding goals: how can the results from a French on-line survey feed the design of relevant breeding programs? **970**
T. Kistler, B. Basso, A. Lauvie, F. Phocas

Deriving cow methane traits and their genetic relationships with feed intake, energy balance and nitrogen utilisation efficiency **971**
M. Stassen, K. Brügemann, C. Grelet, M. Calusinska, S. König

Statistical and genetic analysis of udder conformation traits recorded by automatic milking systems in Fleckvieh cows **972**
S. Hosseini, B. Zumbach, T. Shabalina, R. Emmerling, J. Ertl, A. R. Sharifi

Development of a new recording scheme for calf-health related traits **973**
B. Fuerst-Waltl, C. Fuerst, C. Rehling, C. Egger-Danner, K. Linke

Genome-Wide Association Study of Navel Length at Weaning in Brangus Cattle **974**
T. De Melo, D. De Oliveira, S. Rocha, S. Lazaro, H. De Oliveira

Phenotyping strategies to enhance genetic gain for animal health and welfare in dairy cattle – from the past to future perspectives **975**
C. Eggerdanner, A. Köck, C. Fürst, H. Schwarzenbacher, K. Schodl, J. Himmelbauer, B. Fürst-Waltl

Poster Session 57

An impact of including methane emission into the Polish Holstein-Friesian cattle breeding program **976**
G. Cieleń, M. Pszczola, L. Büttgen

Genetic background of Navel Length in Brangus Cattle **977**
T. De Melo, D. De Oliveira, S. Rocha, S. Lazaro, H. De Oliveira

Genome-Wide Association Study for Hair Coat Score in Brangus Cattle **978**
D. De Oliveira, S. Rocha, S. Lazaro, H. De Oliveira, T. Melo

Genomic evaluation of weaning coat score in Brangus cattle using BLUP and ssGBLUP **979**
D. De Oliveira, S. Rocha, S. Lazaro, H. De Oliveira, T. De Melo

Session 58. From Phenomics to Practice: Phenomics, Interoperability, High dimensional data processing and On-Farm Decisions

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Kaya, Schiavo - Commission(s): G, PLF - Session Type: Project session

Theatre Session 58

Supporting dairy cows breeding practices using historical fertility data and MIR spectra : a deep learning approach **980**
T. Przybylski, C. Grelet, L. Dale, Y. Ben Mohamed, J. Leblois, H. Soyeurt, F. Dehareng

GEDA: A novel software for automated processing of sniffer-based gas emission measurements **981**
L. Ashayeri, S. Annadatha, R. B. Stephansen, T. M. Villumsen, N. Saedi, M. S. Lund, V. Milkevych

Should she stay or should she go now? Ranking of cull cows based on Net Present Value implemented in Dairy Management Software **982**
B. Hoejlund Nielsen, L. A. Hjort Nielsen, N. H. Schneider Nielsen, J. Ettema, S. Oestergaard

High-throughput video phenotyping of sow activity around farrowing and its association with piglet mortality **983**
A. Poublan-Couzardot, T. Cochou, F. Laperruque, W. Hébrard, M. Bonneau, L. Canario

Seasonal adaptation is associated with systemic metabolic remodelling in heavy pigs: a molecular phenomic approach **984**
S. Agyabeng, S. Bovo, M. Gallo, G. Schiavo, L. Fontanesi, F. Bertolini

Comparison of classification models to estimate lifetime productivity of Murciano-Granadina goats from first-lactation records **985**
M. P. Torralbo-Muñoz, Á. Sevilla-Molina, M. J. García-García, E. Padrón-Tejera, F. Maroto-Molina, D. Guijo-Rubio, P. A. Gutiérrez-Peña, J. Fernández-Álvarez

Is gut microbiome information to be considered as part of the animal phenomic realm? **986**
F. Tiezzi, C. Maltecca

Exploring European Family Farmers' Attitudes Towards Big Data Tools **987**
E. Eriksson, D. K. Mcgrath

Use of new digital and "omics" technologies data in animal breeding: opportunities and issues **988**
J. P. Bidanel, F. Laperruque, Y. Billon, C. Bertrand, M. H. Pinard-Van Der Laan

Economics of smart livestock farming technologies – Current costs and benefits and the need for more harmonised estimation approaches **989**
J. K. Niemi, Y. Fu, M. Pastell, A. Stygar

Stakeholder Role Differences in the Use of Precision Livestock Farming Technologies in Europe **990**
C. Gao, D. Liu, Ç. Y. Kaya, S. Orlandini, M. Ryynänen, J. Marchewka, J. Niemi, A. Tolmačev, E. Eriksson, D. Čenejac, T. Norton

Connecting the Dots: Interoperability from Regulation to Practice **991**
C. Y. Kaya, J. Niemi, H. Kayhan

Session 59. Regional Pathways of Dairy Development: Productivity, Sustainability and Climate-Smart Innovation

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Cieslak, Montanholi, Kuipers - Commission(s): C - Session Type: Theme session

Theatre Session 59

Development of Sustainable Dairy Production in Germany - learnings from the "Dairy Sustainability Tool" project **992**
K. Agethen, H. Kuhnert, B. Lassen, T. Lindena, A. Raschel, H. Nieberg

Outlook of a dairy farmer from Northern Germany: Strategies for resilient milk production **993**
J. Riecken, R. Loges

Key developments and scientific focus fields in European dairy farming systems **994**
G. Van Duinkerken

Which livestock systems best address both food insecurity and climate change? Comparing cattle, pig, poultry, rabbit, and snail systems in Cameroon. **995**
L. Germer, M. Moleman, J. Tabot, C. Van Middelaar, S. Oosting, E. Kingsley, P. Gerber

Current developments in the dairy sector in the USA **996**
A. De Vries

CO2 tax and N-legislation constrain Danish dairy production **997**
N. I. Nielsen

Regenerative agriculture as an evolving concept: emergent practices and farmer decision-making in Dutch dairy farming **998**
J. Threels, E. Bokkers, E. De Olde

Producer Mental Health and Wellbeing as a Critical Component of a Resilient and Sustainable Agricultural System: Insights from Canada **999**
H. Watson

Poster Session 59

Milk Quality Driven by Training Programs and Technical Support in Small and Medium Scale Dairy Farms **1000**
L. C. Roma Junior, L. El Faro, M. Perissinotto, W. V. B. Soares

Examination and comparison of measured and scored body conformation traits of German Holstein cows in 2015 and 2025 **1001**
M. Rozing, D. Warder, F. Rosner, H. Scholz, A. Braune, C. Schmidtmann, M. Wensch-Dorendorf

Evaluating greenhouse gas emissions of different breeding sheep pilot farm in Latvia **1002**
D. Ruska, L. Berzina, D. Kairisa, D. Barzdina, L. Paura

Environmental Sustainability as a Dimension of Sheep and Goat Product Valorization: Preliminary Results from a Carbon Footprint Study of Greek Cheeses **1003**
A. Smeou, M. Koureas, A. Manouras, I. Boziaris, E. Malissiova

Session 60. Animal microbiomes - moving forward from taxonomic to functional information - in conjunction with the Horizon 2020 Holoruminant project - Part 2

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Seifert, Kenny - Commission(s): PH - Session Type: Theme session

Theatre Session 60

Translational rumen microbiome research to improve cattle production sustainability **1004**
L. Guan

Genome-wide analysis indicates host genetic control of ruminal microbial traits in Holstein cows **1005**
I. T. Vourlaki, O. Furman, L. R. Porto-Neto, I. Tapio, D. Fischer, L. L. Guan, S. M. Waters, P. B. Pope, D. P. Morgavi, A. Reverter, I. Mizrahi, Y. Ramayo-Caldas

Host genomic influence on Gut microbiome diversity and composition in Atlantic salmon during Saltwater production phase. **1006**
E. O. Odah, H. Dvergedal, J. Ødegård, G. Klemmetsdal, A. Vera Ponce De Leon, S. R. Sandve, L. Hall, G. F. Difford

CowPi 2: Enhanced functional inference from rumen microbiome 16S rRNA data using a comprehensive genome database **1007**
C. Creevey, J. P. Wilkins, L. Dillon, N. Dimonaco, K. Lawther

An Expanded Isolate and Genome Collection of Rumen Bacteria Reveals Microbial Signatures of Feed Efficiency in Cattle **1008**
L. Scott, A. Z. Rahman, A. Alizadeh, L. L. Guan, T. A. Mcallister, H. Derakhshani

Persistent Auxiliary Microbiome of Early Colonizers Shapes the Developing Rumen Ecosystem **1009**
O. Furman, I. Mizrahi

Effect of birth delivery method on microbial colonisation of key gastrointestinal regions in neonatal beef calves **1010**
M. M. Stafford, P. E. Smith, S. Waters, E. O'Hara, F. Buckley, D. A. Kenny

Impact of pastures composition on calves microbiota in saliva, rumen and feces **1011**
C. Lauer-Weich, G. Mesbahi, F. Leiber, J. Werner, J. Seifert

Multi-block sPLS-DA Shows That Plasma Metabolomics Most Accurately Classifies Piglets Across Production Chains than fecal metabolomics and metagenomics **1012**
F. Correa, D. Luise, P. Trevisi

Genome-Resolved Profiling of an Expanded Swine Gut Isolate Collection Reveals Functional Signatures of Health and Disease **1013**
A. S. M. Z. Rahman, F. M. Loojaly, S. Walkowiak, C. Yang, H. Derakhshani

Characterization of the core porcine microbiota across production phases, animal tissues and genetic lines in an integrated production system **1014**
G. De La Fuente Oliver, A. Morillo, P. Fernandez, L. Escudero, D. Villalba

Variability of vaccine responses in laying hens: assessing the holobiont **1015**
A. Racanati, T. Tribout, L. Brulin, A. A. M. Sabuj, F. Blanc, A. Lecoeur, S. Brard-Fudulea, N. Bruneau, D. Gourichon, B. C. D. Cuyabano, T. Burlot, L. Becot, D. Schokker, M. Calus, M. H. Pinard-Van Der Laan, F. Calenge

Poster Session 60

Microbiota dynamics and core taxa in milk, teat skin, and feces of cows with and without mastitis **1016**
I. Tapio

Rumen colonization and succession of microbial guilds during lamb development is affected by the presence of the dam **1017**
L. Voland, P. Dou, J. Tournayre, A. Ortiz-Chura, A. Dehornoy, D. Graviou, K. Vazeille, D. Morgavi, M. Popova

Associations between rumen and faecal microbiota and inflammatory status in transition dairy cows **1018**
J. Jeyanathan, S. Heirbaut, M. Zhang, K. Hertogs, E. Stevens, B. Aernouts, L. Vandaele, V. Fievez

The effect of fat type and inclusion level on the rumen microbiome and methane in dairy cows **1019**
S. J. Noel, P. Lund, A. A. Schönherz, M. R. Weisbjerg, G. Giagnoni

Effects of Heat Stress on gut microbiota in Iberian and crossbred pigs **1020**
L. Sarri, J. Balcells, E. Labussiere, A. R. Seradj, G. De La Fuente Oliver

Session 61. Next generation nutrition solutions for poultry

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Kreuzer-Redmer, Camarinha Silva, Lambert - Commission(s): N, PO - Session Type: Theme session

Theatre Session 61

Utilization of free amino acids in broiler chickens revisited **1021**
W. Siegert

Effects of controlled lactic acid bacteria fermentation on physicochemical properties of rye and wheat grains **1022**
S. Salehi, M. F. E. Ahmed, A. Godglück, J. Gickel, A. Abd El-Wahab, A. Von Felde, C. Visscher, C. B. Arnold

Impact of dietary Foeniculum vulgare Mill. on the growth performance of broiler chickens: Insights from a meta-analysis **1023**
C. F. Egbu, C. J. Smit

Effects of dietary Saccharomyces cerevisiae-derived postbiotic on growth performance, intestinal morphology, serum biochemistry, hepatic metabolome and mineral deposition in broiler chickens **1024**
T. Alkaabi, S. Almansoori, W. Alkaabi, O. Alsheblak, A. El Awad, R. Seboussi, M. Abdelmegeid, M. Mohamadin, M. Shukry, I. Yoon, A. Elolimy

Multigenerational effects of in ovo synbiotic and choline supplementation on gut microbiota diversity and composition in broiler chickens **1025**
K. Stadnicka, J. Gawor, T. Aleksandrzak-Piekarczyk, E. Grochowska

Low protein diets in broilers chickens: insight from a holistic evaluation **1026**
T. De Rauglaudre

Comparative effects of a multi-carbohydrase and single xylanase supplementation on broiler performance and environmental impacts **1027**
C. Gras, S. Salami

Multi-carbohydrase and bacterial 6-phytase co-supplementation improves performance, nutrient digestibility and feed cost efficiency in broilers fed nutrient-reduced corn-soybean meal diets **1028**
S. Salami, H. Yakout

Phytogenic dietary inclusion level modulates key performance indicators and meat quality biomarkers in heat-challenged broilers **1029**
I. Brouklogiannis, E. Iliopoulou, E. Misirli, A. Kouvatsou, G. Kefalas, K. C. Mountzouris

Effect of black soldier fly larvae oil and feed withdrawal on productive performance in broiler chicken subjected to cyclic heat stress during the final growth period **1030**
M. K. Atehortua, A. J. Maldonado, F. Sevillano, A. I. Rey, M. A. Ibáñez, D. Menoyo

Effect of Marine mineral complex on skeletal mineral deposition and liver health in aging laying hens **1031**
O. A. Demehin, M. A. Bouwhuis, K. Kozłowski, A. Van Vilsteren, S. O'connell

Poster Session 61

Assessing Selenium Source Bioavailability via Excretion Patterns in Broiler Feces **1032**
S. Poulain, E. Chevaux, L. Vigier, Y. Le Treut, A. Sacy

Embryonic stage-dependent effect of in ovo synbiotic administration at day 12 vs. day 18-implications for immunocompetence conditioning **1033**
K. Stadnicka, C. Randazzo, K. Guinan, K. Skowron, K. Grudlewska-Buda, J. T. O'Sullivan, J. Bogucka

Lipid structure and energy utilization in high-performance broiler diets: impacts on performance, carcass traits and oxidative status **1034**
R. Schemmer, C. Heidemann, H. Rashid, R. Puntigam

Enhancing broiler chickens' performance through synergistic citrus extract prebiotic and probiotic supplementation **1035**
S. Cisse, A. Mansour, C. Maltret, M. E. A. Benarbia

Evaluation of protected sodium butyrate supplementation to optimize gut health biomarkers in broiler chickens **1036**
A. Kihal, A. Y. Alhady, A. Radwan, M. Puyalto, J. J. Mallo

Effects of Dietary Energy Levels During the Growing and Early-Laying Periods on Late-Laying Performance, Egg Quality, and Organ Characteristics in Laying Hens **1037**
J. Hong, H. Kim, Y. Kim, E. C. Hong, C. Lim, H. J. Kim, M. Yu, H. K. Kim, D. Lee

Session 62. Feeding, grazing and housing management to lower nitrogen and methane emission pressure to the environment

Date: Wednesday 9 September 2026; 14:15 - 18:00
Chair(s): Dohme-Meier, Cieslak - Commission(s): C, N - Session Type: Theme session

Theatre Session 62

Climate protection and food security: antagonists or synergists in grassland-based production? **1038**
F. Leiber

Enhancing MIR-based methane prediction through systematic integration of cow- and farm-level information **1039**
C. Matzhold, A. Köck, S. J. Burn, K. Linke, C. Schmid, M. Mayerhofer, C. Egger-Danner

Methane emission and feeding behavior of dairy cows grazing versus indoor feeding with silage **1040**
D. W. Olijhoek, N. P. Hansen, M. R. Weisbjerg, M. Maigaard, P. Lund, M. Larsen

Comparison of two approaches for quantifying methane emissions at housing or individual animal level **1041**
K. Orquera-Arguero, M. Zähner, F. Dohme-Meier, G. Lazzari, S. Schrade

Diurnal profiles of methane emission in response to feed intake patterns of cattle: Implications for GreenFeed measurement sampling schemes **1042**
H. J. Van Lingen, U. Arshad, M. Niu, J. L. Ellis

Projecting threshold of annual non-fossil methane emissions at which the atmospheric methane burden equals methane removal **1043**
Ž. Pečnik, J. Verbič

Variation in N and P excretion in manure from dairy farms **1044**
C. F. Børsting, A. L. F. Hellwing, M. J. Brask, P. Kai, H. Martinussen, A. M. Kjeldsen

Feeding strategies to reduce dietary crude protein levels and ammonia emissions on dairy farms **1045**
M. Moleman, A. M. Smid, P. Galama, T. Wind, M. De Haan, M. J. Paulo, S. K. Schnabel

Long-term effects of reduced dietary protein supply in lactating dairy cows **1046**
T. Michou, M. R. Weisbjerg, M. Larsen, S. E. Räisänen

Quantitative meta-analysis on the effects of manipulating rumen degradable protein balance by changing protein degradability on fat and protein corrected milk in Holstein dairy cows **1047**
E. Parand, H. Van Laar

Impact of diet optimisation on diet carbon footprint intensity and productive performance of lactating dairy cows **1048**
R. Schmith, R. Tonucci, M. M. Campos, J. P. Matiello, M. A. C. Danes, J. P. P. Rodrigues, A. Rytz, C. Powell, J. B. Daniel, A. B. P. Fontoura, M. E. Van Amburgh, R. Rauch

Grazing, feeding, manure and air management for dealing with environmental impacts of intensive dairy farming **1049**
A. Kuipers, P. Galama

Poster Session 62

Farm level analysis of on-farm monitoring of methane from dairy cows and relationship to farm characteristics and farm level climate accounts **1050**
K. Horsted, L. Sembach, G. Giagnomi, P. Lund, T. M. Villumsen, H. Schneider, A. M. Kjeldsen, L. Mogensen

Carbon farming potential of Mediterranean cow–calf systems under different cultivation intensities **1051**
M. F. Lunesu, S. Sechi, F. Correddu, S. Carta, S. P. G. Rassu, G. Pulina, G. Battacone, A. Nudda

Seasonal variation in enteric methane emissions and production efficiency metrics in a higher-output Irish pasture based dairy system including concentrates with differing levels of crude protein. **1052**
F. Monaghan, K. M. Mccarthy, K. M. Pierce, Z. C. Mckay, Y. Kavanagh, N. Dooley, F. J. Mulligan

Environmental impact of pasture turnout strategies in dairy cows grazing timothy–meadow fescue pasture **1053**
G. Mantovani, M. Vadronova, M. Ramin, P. Fant

Forage type and lipid-rich concentrates as practical levers to mitigate enteric methane in fattened lambs: links to rumen fermentation and methanogenic microbiota **1054**
J. Łodyga, B. Borys, E. Wawrzyniak, W. Warguła, M. Szott, S. Olorunlowu, A. Cieślak

Evaluation of dibromomethane as an anti-methanogenic feed additive for dairy cows in a dose-response study **1055**
M. Thorsteinsson, A. L. F. Hellwing, P. Lund, M. R. Weisbjerg

Grape stem inclusion in the diet of fattening young bulls reduced methane emissions **1056**
D. Villalba, I. Casasús, M. Joy, S. Lobón, M. Blanco

Impact of sainfoin (Onobrychis viciifolia) inclusion in beef fattening diets on methane emissions **1057**
D. Villalba, E. Molina, I. Casasús, M. Joy, M. Blanco

Optimizing fattening duration in Hanwoo steers: Impacts on growth performance, enteric methane emissions, feed efficiency, and rumen microbial communities **1058**
J. I. Berdos, K. S. Dhia, M. Miguel, M. N. Aprilliza Am, S. Begum, Y. P. Naing, A. R. Son, K. S. Baik, K. C. Nam, S. H. Kim, S. S. Lee

Isotope patterns in fiber fractions of grass samples with high variability in nitrogen content **1059**
T. M. Liegsalz, T. Hofmiller, J. Kurek, C. Ostendorf, R. Schäufele, G. P. Bienert, S. Muetzel, S. Colombini, F. Giudice, L. Rapetti, J. Steinhoff-Wagner

Use of essential oils on enteric methane emissions and ruminal microbiota of finishing feedlot Nellore cattle **1060**
M. Dalafini, M. Marques, E. Furlan Junior, C. Franzon, J. Michelini, F. Oristanio, E. Magnani, R. De Freitas, L. Drouet, R. Dari, T. Da Silva, R. H. Branco

Effects of condensed tannin extract supplementation on performance, carcass traits, and methane emissions of feedlot cattle fed diets with different protein profiles **1061**
R. V. Ribeiro, O. L. Rigobello, W. R. Meireles, I. A. Dornellas, I. M. C. Tarôco, M. M. Silva, I. M. Ferreira, J. D. Messana, R. A. Reis

Does a combination between protein reduction and yeast probiotic in the diet of dairy cow impact feed efficiency, nitrogen use, digestibility and rumen microbial protein synthesis? **1062**
N. Salah, B. Gestes, P. Ly, K. Hadjeba, J. Schulthes, J. Duclos, E. Pinloche, M. Mayer

Testing coated calcium peroxide for methane mitigation in dual-flow fermenters **1063**
A. Hall, S. Mills, V. O'Flaherty

Nitrogen balance and nitrogen use efficiency in extensive Charolais beef cattle systems facing nitrate water pollution risk **1064**
R. Ibidhi, M. Ubertosi, A. Cavillon, A. Tanda, P. Rolland-Muquet, Y. Moulin

The environmental impact of dairy cattle farming using Life Cycle Assessment: a meta-analysis **1065**
V. Thymis, D. Kantas, A. Foskolos

Modeling carbon cycle from dairy cows, barn, and storage **1066**
M. Brask, S. Lashkari, F. R. Dalby, C. F. Børsting

Temperature-driven seasonal variation of soil CO_2 and N_2O emissions under rotational and continuous grazing in a Mediterranean grassland **1067**
D. Sarkar, G. Bernabucci, C. Rossi, G. Grossi, C. Evangelista, R. Primi, N. Lacetera, A. Vitali

Mitigating emissions from manure: The effectiveness of biochar under real dairy farm conditions **1068**
K. Kaikiti, K. Philippou, A. Phokas, P. Pissaridou, C. Hadjimichael, J. Rhodosthenous, A. Rossis, A. Houvarta, D. Sparaggis, M. Omirou

Effect of ventilation regimes on carbon and nitrogen dynamics in composted bedded packs for Mediterranean dairy cattle production **1069**
X. Díaz De Otálora, B. Fajardo, C. Cano, T. Monreal, A. Villagrá, F. Estellés

Interaction between protein source and condensed tannin extract on nitrogen metabolism in feedlot cattle **1070**
R. V. Ribeiro, P. S. Marchiori, I. A. Dornellas, M. A. D. O. Castro, A. M. Kirchhoff, J. V. D. P. Germano, P. A. A. Fredes, I. M. Ferreira, J. D. Messana, R. A. Reis

Low crude protein diet balanced for metabolizable methionine positively impacts performance, metabolic status and N emissions in high-yielding dairy cows **1071**
A. Vigh, M. Müller, V. V. Thierer, J. Guyader

Session 63. Climate-smart livestock systems - holistic approaches to adaptation and mitigation to deliver global protein needs

Date: Wednesday 9 September 2026; 14:15 - 17:30
Chair(s): Rivero, Mantino - Commission(s): LFS - Session Type: Theme session

Theatre Session 63

Multifunctional utilisation of dual-purpose cropping for pasture, forage & grain **1072**
M. Hetta, L. Post, G. Carlsson, G. Bergkvist, E. Ekholm, V. Picasso, S. Delin, D. Parsons

Innovation in the U.S. Beef Value Chain: A Sustainable Beef Research Roadmap **1073**
S. J. Werth, G. D. Vehige, S. Place, L. R. Thompson, T. N. Rowan, D. J. Goodwin, J. E. Rowntree, P. L. Stanley, S. T. Metzger, K. L. Wagner

Optimal deployment of genetic innovation is essential to increasing the productivity and sustainability of global cattle production systems **1074**
M. A. Cleveland, E. Lai

Synergistic modulation of ruminal kinetics and metabolic efficiency by Lithothamnium calcareum and oregano extract: A holistic framework for sustainable bovine production **1075**
J. Pena, G. Mañas, X. Rodriguez

Environmental, economic, and technical performance of goat farming systems compared to cattle and sheep systems: A systematic review and meta-analysis across climatic regions **1076**
J. J. Minviel, S. Souissi

Sustainable ruminant livestock transformation through the Global Farm Platform: The hub-and-spoke network **1077**
J. Rivero, M. Lee

Grazing management intensification increases pasture height and carrying capacity in native grassland livestock systems: early results from a long-term farmlet experiment **1078**
F. Montossi, T. Devincenzi, V. Porcile, J. Martin

Summer-smart strategies for livestock production in temperate zones: impact of shade on performance of grazing cattle **1079**
P. Rovira

Dairy Soil and Water Regeneration Research: Filling Crucial Data Gaps **1080**
D. Busch

Differential sensitivity of milk protein and milk yield to heat stress load in a robotic pasture-based dairy system **1081**
F. Ahmadi, F. Dunshea

Poster Session 63

Summer-smart strategies for livestock production in temperate zones: supplementation of grazing cattle **1082**
M. Verdaguer, P. Rovira

Fifty years of progress for beef cattle production in the United States **1083**
C. A. Rotz, J. Castano-Sanchez, D. Kniffen, M. Buyers, S. J. Werth

Climate change and thermal stress in cattle: Global projections with high temporal resolution **1084**
M. Neira, P. Georgiades, Y. Proestos, T. Economou, J. Araya, S. Malas, M. Omirou, D. Sparaggis, G. Hadjipavlou, J. Lelieveld

Fans, sprinklers, or what else? Understanding Swedish farmers' experiences with cooling strategies **1085**
K. Berggren, L. M. Tamminen, N. Högberg, R. Båge, G. Olmos Antillón

Aligning research gaps and innovation demands for ecosystem services in South American pasture-based livestock systems **1086**
F. Montossi

Effect of reproductive status on goat methane emissions **1087**
M. Moradi, A. Beasley, L. C. Hoffman, S. J. Meale

Needs and Capacity building of advisors to support transitions towards climate-smart farming systems **1088**
F. Bedoin, C. Evrat-Georgel

Integrating thermal load and metabolic indicators to support climate smart management decisions in dairy herds **1089**
Z. Vassilev, L. M. Dale, J. Bieger, A. Al Baqain, E. J. Strang, C. Eck, S. Weidmann, S. Fritsch

Session 64. Efficiency and mitigating emissions in pig production – strategies to reduce nitrogen and phosphorus losses, including amino acid nutrition - Part 2

Date: Wednesday 9 September 2026; 14:15 - 17:45
Chair(s): Girard, Lawlor, Chalvon Demersay - Commission(s): P, N - Session Type: Theme session

Theatre Session 64

Effects of dietary supplementation with a novel marine algae–derived prebiotic feed additive (MAFA) on growth performance, gaseous emissions and manure characteristics from a commercial finishing pig facility **1090**
I. M. Aroh, G. Mccutcheon, R. Kuneš, S. Conolly, E. G. Manzanilla, T. P. Curran, L. Clarke

Impact of dietary calcium and phytase on mineral digestibility and skeletal mineral accumulation in growing pigs. **1091**
J. Labarre, P. Schlegel, P. Schmidely, T. D. Crenshaw, D. Bueno Dalto, M. Jlali, A. Narcy, M. P. Létourneau-Montminy

Nutritional Strategies to Enhance Phosphorus Utilization Efficiency in Pigs **1092**
N. Coquil, M. P. Létourneau-Montminy

Valorization of native trace minerals in alternative feed ingredients for sustainable pig production **1093**
Y. J. Manaig, C. De Cuyper, A. Rigo Monteiro, S. Durosoy, S. Millet

Terrestrial ecotoxicity and phosphorus excretion are reduced by increasing phytase and reducing nutrient concentrations in growing pig diets **1094**
G. Mota, B. Taynah, M. Souza, W. Sardi, G. Araújo, T. Cabral, B. Oliveira, R. Nunes, P. Pozza

Comparative Analysis of Three Approaches for Estimating Phosphorus Retention in Growing Pigs: Implications for Phosphorus Excretion Estimates **1095**
K. R. Aklikokou, L. Cappelaere, F. Garcia-Launay, M. P. Létourneau-Montminy

Pig gut microbiome functional genes associated with protein metabolism along the gastrointestinal tract **1096**
D. Lee, N. Sarpong, J. Seifert, A. Camarinha-Silva

Transcriptomic signatures of nitrogen use efficiency in liver and muscle of Swiss Large White pigs under protein-restricted feeding **1097**
B. Monney, C. Kasper

Phenotypes for implementing proxies of mineral utilisation and bone turnover in pig breeding **1098**
A. K. Solomon, M. Oster, H. Reyer, M. Scheeder, M. Leible, J. Massmann, K. Wimmers

A mechanistic model to simulate the digestive fate of calcium and its interaction with phytate and phytase in growing pigs. **1099**
J. Labarre, P. Schmidely, A. Narcy, M. Jlali, P. Schlegel, C. Loncke, M. P. Létourneau-Montminy

Meta-analysis of urinary calcium and phosphorus excretion as predictors of mineral status and dietary imbalances in growing pigs **1100**
P. Floradin, M. P. Létourneau-Montminy

Session 65. Animal welfare free communications

Date: Wednesday 9 September 2026; 14:15 - 17:45
Chair(s): Trocino, Almeida - Commission(s): HW, SG, P, G - Session Type: Challenge session

Theatre Session 65

Health and management of unweaned calves on conventional and regenerative dairy farms **1101**
E. Bokkers, J. Threels, F. Braakhuis, E. De Olde

Implications of birth order on piglet survival **1102**
R. Muns, C. Mulvenna

Risk factors in fattening rabbit housing: The role of animal density and bedding **1103**
S. Cazzato, S. Gebhardt-Henrich, H. Würbel, D. Wiederkehr, J. Schwarz

Effect of group housing on behaviour and welfare of rabbit does in Mediterranean farming conditions **1104**
C. L. Manuelian, K. Guirrati, A. Torra, A. A. K. Salama, X. Such, J. L. Ruiz De La Torre, C. Casas, F. X. Mora

Effects of housing and management strategies on productivity and welfare of young rabbit does **1105**
M. Molin, F. Bordignon, M. Pravato, A. Zuffellato, A. Trocino, G. Xiccato

Acute ammonia concentration peaks present a delayed effect on reproductive and productive performance of rabbit does **1106**
A. Villagrá García, S. Calvet Sanz, J. Sahuquillo, F. Estelles Barber

Selected best practices for improving on farm welfare of rabbits: interrelationships with sustainability pillars **1107**
C. Tolini, A. Miolo, S. Rota Nodari, Z. Sudiak, G. Aubin-Houzelstein, F. Bordignon, M. C. Ceballos, E . Fàbrega, G. Xiccato, F. Fusi, A. Trocino

On-farm hatching in broiler production: Field experiences with slow- and fast-growing genotypes in Germany **1108**
B. Spindler, S. C. M. Vossler, S. Schäfers, J. Heck, M. C. Bosello, E. Rauch, H. Louton, P. Hiller, F. Dietzel, N. Kemper, A. Schwarz

Minimal evidence for locomotor imitation in pullets: Insights from a ramp vs. jump two-action procedure **1109**
K. Walsh, L. Nicklas, B. Tobalske, E. Planchon, N. Van Staaveren, D. Powers, T. Widowski, B. Willie, A. Harlander

Opinion of the FRCAW on the impacts of loading density on fall and injury risks in cattle and pigs, and on piling-up behaviour and injury risks in poultry **1110**
C. Bezançon, L. Kremer, V. Colson, A. L. Dauphiné-Morer, A. Tiret, Frcaw Panel Of Experts, G. Aubin-Houzelstein

Catching and loading of end-of-lay laying hens: effects of body position on endocrine and respiratory stress responses **1111**
L. Jung, A. Schwarz, C. Touma, T. Wolf, N. Kemper, B. Spindler

Comparative assessment of euthanasia methods for RNA integrity in rainbow trout (Oncorhynchus mykiss) larvae **1112**
I. Kilic, S. Rosenau, A. C. Mott, S. Zeidler, F. J. Gentz, J. Tetens

Poster Session 65

Do stray currents impact the behavior, health and performance of dairy cattle? The farmer's perspective **1113**
C. Gazaix, F. Lascaze, P. Lemaire, T. Quemener, Y. Lecozler, V. Lollivier, A. Michaud, S. Brajon, L. Hervé

Assessing the effect of trees on the welfare of dairy cows by limiting insect pressure **1114**
C. Bonnefous, A. L. Hochstrasser, N. O. Verhulst, Z. Amsler, V. Maurer

Analysis of the behavior of finisher pigs in the 24 hours before death on a commercial farm **1115**
M. Okayasu, Y. Sasaki

The restraint enclosure effects due to African Swine Fever on the reproductive parameters, ethology patterns and welfare of boars and sows of the free-range Greek autochthonous black breed. **1116**
C. Kalfopoulos, V. Tsartsianidou, A. Moulistanos, A. Triantafyllidis, G. Vatzias

New house, stressed cows? Behavioural observations following relocation to a new barn **1117**
T. Rahmann, A. Langehennig-Peristenidou, N. Kemper, N. Volkmann

Does choice of calving location affect calving duration? **1118**
T. Tammen, A. Haeussermann, E. Hartung

Opinion of the FRCAW on the Effects of Transport on the Welfare of Calves under Five Weeks of Age **1119**
V. Colson, C. Bezançon, L. Kremer, Frcaw Panel Of Experts, G. Aubin-Houzelstein

Development of a research and demonstration barn to improve animal welfare in dairy husbandry and to regain societal acceptance **1120**
L. Bachmann, M. Zenk, R. Wulf

Session 66. Rethinking Equine Production in a Systemic Perspective

Date: Wednesday 9 September 2026; 14:15 - 15:30
Chair(s): Tapprest, Mecocci - Commission(s): H - Session Type: Theme session

Theatre Session 66

Exploring the future of the European equine sector towards 2040: a participatory foresight approach **1121**
European Horse Network, 4Sing, A. Julien, L. Rosier, F. Gras, H. Blauw, M. Addes

Professional Conceptions of Equine Wellbeing: Continuous Adjustment Grounded in Observation, Expertise, and a Human–Horse Moral Contract **1122**
M. Felga, C. Vial, B. Siadou-Martin

The INOSYS portal, open access equine references **1123**
G. Mathieu

Cost of production: a management tool for equine businesses **1124**
S. Boyer-Lafaurie

Poster Session 66

Ecosystem restoration potential of equine farms – development of a practical and scalable framework supporting the EU Nature Restoration Law **1125**
L. Lovasz, I. Sereda, V. Milojevic, B. Robert, C. Zemp

An Economic Overview of Equestrian Tourism in France **1126**
C. Vial, A. Batouche, P. Heydemann, J. Laulhere, M. Primault, C. Drapeau

Session 67. Human-animal relationship: handling methods and welfare for horses and farm animals

Date: Wednesday 9 September 2026; 16:15 - 17:45
Chair(s): O'Driscoll, De Palo - Commission(s): H, HW - Session Type: Theme session

Theatre Session 67

Relational practices in beef suckler systems: A literature review, holistic modelling, and emerging research questions **1127**
X. Boivin, G. Barbier, E. Delanoue, R. Lardy

Traffic noise exposure alters horse behaviour at pasture **1128**
J. Henke-Von Der Malsburg, U. König Von Borstel

Acoustic relationships between bovine vocalizations and traditional herding songs: implications for human–animal communication and cattle handling under grazing conditions **1129**
P. Betancourth-Chaves, J. Montoya-Zuluaga, N. Alvarez-Hernandez, B. Rodriguez, D. Vallejo-Timaran

Behavioural indicators of the emotional state of outdoor managed pigs during an animal-human approach test **1130**
O. Menant, L. Frigerio, É. Peyrard, L. Boyle, K. O'Driscoll

Conflict behaviours and potential "positive" behaviours in horses ridden in a low level training situation in their home setting **1131**
I. Czycholl, J. Winther Christensen, L. Veje Johansen

Poster Session 67

Human perception of horses' facial expressions: implications for equine welfare assessment **1132**
C. Brunet Claret, I. Blanco-Penedo, S. Sund Hagelberg, A. Torra Burgués

Perceptions of equine welfare and the human–horse relationship within the equestrian community **1133**
C. Brunet Claret, A. Torra Burgués, S. Sund Hagelberg, I. Blanco-Penedo

Session 68. Young EAAP

Date: Wednesday 9 September 2026; 14:15 - 15:45
Chair(s): Adriaens, Gislon, Koch, Obsteter - Session Type: Theme session

Theatre Session 68

Young EAAP session - impact, career building and workshops **1134**
I. Adriaens, G. Gislon, F. Koch, J. Obsteter

Session 69. Animal Welfare Aspects and Future Perspectives in Sheep and Goat Production

Date: Wednesday 9 September 2026; 14:15 - 17:30
Chair(s): Campion, Almeida - Commission(s): SG, HW - Session Type: Theme session

Theatre Session 69

Productivity and behavioural monitoring of dairy goats under heat stress conditions **1135**
D. Mendez, D. R. Yanez-Ruiz, A. Gómez, B. Farjardo, M. Hassan, A. Sánchez-Garcia, F. Estelles, M. Romero-Huelva

Feeding preferences of sheep grazing dryland pastures in Montado: influence of crude protein and neutral detergent fiber **1136**
E. Carreira, J. Serrano, F. G. Silva, N. Borges, E. Mata, M. Cruz, M. Braz, S. Travessa, A. Geraldo, R. Silva, R. Charneca, A. Pereira

Managing genetics of resistance to parasites in goats: Reviews at different scales of diversity to implement agroecological breeding systems in the tropics **1137**
C. De La Cruz, J. C. Bambou, N. Mandonnet

Evaluation of Haemonchus contortus-derived extracellular vesicles in modulating sheep immune response in vitro **1138**
Y. Dadi, M. Penati, S. Zanzani, L. De Matos, G. Salvi, R. I. Lazar, S. Cavallero, I. Bellini, F. Ceciliani, C. Lecchi, A. Gazzonis

Genetic parameters for resistance to Small Ruminant Lentivirus (SRLV) in an experimental flock of dairy goats **1139**
R. Rupp, C. Roy, T. Fassier, G. Tosser-Klopp, I. Palhière

Dairy goat welfare: Towards a welfare monitor with more animal-based welfare indicators **1140**
F. Marcato, K. Peterson, F. Neijenhuis, J. Roskam, J. Verkaik

Effects of a higher colostrum intake on health and growth of goat kids in their first 12 weeks after birth **1141**
F. Marcato, A. Brinkman, T. Van Hattum, J. Verkaik

Examining the relationship between somatic cell score, test day milk, and milk composition in different stages of lactation in Cyprus Damascus goats **1142**
L. Koniali, G. Hadjipavlou

Sheep Pox outbreaks in Bulgaria: Epidemiological spread and socio-economic impacts on the sheep farming sector **1143**
D. Dimov, P. Zhelyazkova, A. Vuchkov, K. Kolev

Cooperative handling strategies for group-housed sheep: Short-term training to improve welfare during routine procedures **1144**
J. Henke-Von Der Malsburg, A. Vernunft

Poster Session 69

Impact of dietary supplements, breed and lactation stage on milk somatic cells count in sheep and goats **1145**
M. Farina, A. Cesarani, A. Nudda

CMT Scoring of ewe milk 15-70 days after lambing as an indicator for mastitis in commercial meat sheep flocks **1146**
J. H. Jakobsen, V. Tømmerberg, L. Hektoen, H. B. Olsen, M. O. Gløersen, I. A. Boman, S. Svendsen

Blood Transcriptome and Immune Cell Profiling Highlights Host Defence Variations in Naïve and Immune Goats infected with Gastrointestinal Nematodes **1147**
C. De La Cruz, H. Aboshady, M. Rashid, X. Godard, D. Romil-Granvilled, N. Mandonnet, Y. Felicite, J. C. Bambou

Bioclimatic profile of the rearing areas of local sheep breeds in Montenegro defined by multivariate analysis **1148**
B. Markovic, M. Djokic, M. Zorc, I. Curik, S. Mirecki

Within-day dynamics of milk components in intensively managed Saanen dairy goats. **1149**
J. Kirkham, F. Zamuner, A. Cameron, B. Leury, K. Digiacomo

Farmer attitude to ovine lameness - Where do they seek information when a problem occurs? **1150**
F. Campion, E. Kelly, J. Angel, J. Delaney

Session 70. Challenges and opportunities in farming insects

Date: Wednesday 9 September 2026; 14:15 - 16:30
Chair(s): Naser El Deen, Meijer - Commission(s): I - Session Type: Industry session

Theatre Session 70

Substrate pH: A Critically Overlooked Microenvironmental Factor in Black Soldier Fly Larvae Performance and Systematic Reporting **1151**
E. Parand, A. Reazei Far, D. G. A. B. Oonincx, R. Hao, S. Naser El Deen, T. Veldkamp

Bugs in the System: Have the economic and environmental benefits of insect farming been overstated? **1152**
C. Biteau

Eclosion and mating postponement, how it influences oviposition in black soldier fly (Hermetia illucens) **1153**
C. Coudron, J. Claeys, D. Deruytter

Ammonia emissions during BSFL rearing: initial continuous measurements and the impact of feed protein/carbohydrate ratio **1154**
D. Deruytter, J. Claeys, C. L. Coudron

Computer vision for weight estimation and activity levels in Tenebrio molitor: Improving production and welfare **1155**
E. Osei, M. Wutke, I. Traulsen, J. Tetens, E. Werner, R. H. Mateus-Vargas

Waste Valorization Through Insects: Larval Growth Evaluation of Hermetia illucens on Olive Pomace Diets **1156**
C. I. Rumbos, P. Soulioti, G. V. Baliota, M. T. Capucchio, C. G. Athanassiou

Farming insects: evaluation of safety and legal framework **1157**
N. Meijer, K. Niermans, L. Tromp, S. Naser El Deen, T. Veldkamp, C. J. De Vos-De Jong, M. J. Appel, E. F. Hoek-Van Den Hil

Poster Session 70

Telomere Length as a Biomarker of Health in Apis mellifera **1158**
R. Pistucci, A. Bonfante, G. Di Prisco, A. Iannuzzi

House cricket (Acheta domesticus) powder as an alternative protein source in the development of protein energy bars **1159**
E. Semedo, E. Pereira, B. Carbas, J. Sá Morais, D. Cabral, E. Ramalhosa

Session 71. Breeding for enhanced health and welfare

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Martin, Kargo - Commission(s): G, P - Session Type: Theme session

Theatre Session 71

Improving genomic prediction of juvenile mortality through causal variant inclusion in the Normande dairy cattle breed **1160**
L. Chapard, F. Besnard, T. Tribout, S. Aguerre, C. Escouflaire, H. Leclerc, S. Fritz, S. Mattalia, A. Capitan, P. Croiseau

Insights into the genetic basis of emerging health and vitality related traits in Holstein Friesian calves **1161**
L. Stahmer, L. Schwarz, L. Engel, K. Voß, G. Thaller

Optimizing lesion phenotypes to enable breeding against psoroptic mange susceptibility in Belgian Blue cattle **1162**
I. Patteet, L. Wirix, N. De Wilde, L. De Veerman, S. Janssens, E. Claerebout, C. Charlier, N. Buys, R. Meyermans

Variance components for number of oocytes and number of embryos in Austrian Fleckvieh cattle **1163**
H. Schwarzenbacher, C. Fuerst, J. Miesenberger

Revealing inheritance patterns and genomic regions associated with embryonic loss in Holstein Friesian embryos **1164**
L. Rienesl, L. Hoffmann, M. Diederich, S. Meier, H. Grothmann, E. Tholen, E. Held-Hoelker, M. Hoelker, C. Große-Brinkhaus

Inferring the genetic background of immunity and associated Vitamin D pathway gene polymorphisms in Holstein cattle **1165**
M. Aïbouki, S. Vanvanhossou, I. Giambra, D. Gessner, K. Eder, S. König

Phenotypic Responses of Milk β-Hydroxybutyrate and Somatic Cell Score to Heat Stress in Dairy Cattle **1166**
V. Storing, C. Baes, F. Schenkel, G. Dodd, C. Machefert, F. Malchiodi, C. Richardson, F. Miglior

Characterization of WC1+ porcine γδ T cell subpopulations using transcriptomic data **1167**
A. Chofre, T. Jové-Juncà, C. Hernández-Banqué, O. González-Rodriguez, R. Quintanilla, M. Ballester

Genetic relationship between cardiorespiratory traits assessed via CT imaging with production traits in pigs **1168**
M. Londoño-Gil, Ø. Nordbø, N. G. Leite, J. Dunkelberger, E. Grindflek

Co-occurrence and genetics of feed intake perturbations and drug treatments in pigs **1169**
W. Gorssen, C. Winters, N. K. Kadri, N. Khayatzadeh, H. Pausch

Genomic background of bone-related traits considering a genotype-by-environmental interaction in Landrace boars **1170**
C. Große-Brinkhaus, M. F. Bellersen, E. Jonas, R. Lohmayer, D. A. Brüggemann, E. Tholen

A deterministic epidemiological model of flavobacteriosis in rainbow trout farming: implications for farm management and genetic improvement **1171**
A. Caen, F. Phocas, T. Rochat, E. Duchaud

Mating strategies to increase the polled phenotype in organic dairy cattle production: potential and consequences **1172**
A. Bouquet

Establishment of breeding lines for organic dairy production **1173**
M. Kargo, J. R. Thomasen, R. Zaalberg, M. Hansen, L. P. Sørensen, T. Christensen, S. Denver, H. M. Nielsen

Poster Session 71

Genomic evaluation of a lactation persistency indicator in French dairy cattle breeds **1174**
Q. Berger, M. Barbat, S. Fritz, E. Dugas, C. Moulin, D. Boichard, A. Ben Abdelkrim, R. Rostellato

Prediction of GEBVs for health traits in Australian and German Holstein cattle using Bayesian methods **1175**
A. M. Križanac, C. Schmidtmann, J. Bennewitz, G. Thaller, R. Xiang, A. J. Chamberlain, I. M. Macleod, J. Tetens, M. E. Goddard

Early Good Is Not Late Good: Why Early Performers Are Not Necessarily Finishing-Phase Winners **1176**
S. Götz, H. Geffert, D. Debiasi, U. Höne, I. Traulsen, I. Reker, N. Kemper, J. Probst

Identification of candidate genes and key QTL associated with anogenital distance in Holstein cattle **1177**
S. K. Ashar, G. R. Dodd, S. M. F. Cunha, F. Miglior, F. S. Schenkel, C. F. Baes

Session 72. Integration of Hologenomics and Epigenetics into Animal Breeding

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Bickhart, Tiezzi, Pocrnic - Commission(s): G - Session Type: Theme session

Theatre Session 72

Genomic Diversity and a Haplotype Imputation Reference Panel for Pikeperch (Sander lucioperca) **1178**
Z. Cai, Z. Bai, J. Overton, T. Boutrup, H. M. Nielsen, G. Sahana

Sequence-level genome-wide analysis of hoof disease traits in Swiss dairy cattle populations reveals a polygenic and breed-specific architecture **1179**
S. Vasiljevic, F. R. Seefried, S. Widmer, N. K. Kadri, A. S. Leonard, H. Pausch, A. Steiner, C. Drögemüller, J. Jacinto

Understanding dairy producer's perspective and experience with reporting gestational and developmental dairy calf conditions **1180**
G. Condello, S. Duggan, E. Leishman, R. Jahnel, H. Sweett, C. Bartels, F. Schenkel, J. Cole, C. Maltecca, F. Miglior, C. Baes

Integrating Long-Read Sequencing and SNP Genotyping to Uncover Genetic Determinants of Stillbirth in Holstein Cattle **1181**
Y. Zheng, C. Reimer, F. Fischer, C. Schmidtmann, L. Hüneke, C. Klein, C. Kühn, J. Geibel

Identification of novel shared loci across purebred boar lines influencing the onset of puberty **1182**
P. Sá, C. A. Sevillano, J. M. Tabet, J. Dekkers, R. Fernando, H. Yu, R. M. Godinho, E. Grindflek

Single-step genomic predictions considering QTLs with large effects **1183**
R. Bonifazi, D. Jamieson, M. Bink, K. Janssen, J. Vandenplas

Evaluation of targeted sequencing as a flexible alternative to SNP arrays for routine cattle genotyping **1184**
K. Huijben, E. Francis, P. Doran

Pangenome construction enables detailed investigation of the IGH locus in alpacas **1185**
B. Schmitt, N. Khaveh, A. K. Struck, D. Höltig, J. Metzger

GENIUS: Genotype-Informed Unbiased Selection of Individuals for Efficient Phenotyping **1186**
M. Neuditschko

Discovery of methylated regions from nanopore sequence data of pigs **1187**
C. Reimer, J. Geibel, L. Vollmer, A. Weigend, D. Hinrichs, S. Weigend, C. Klein

Seasonal drought reshapes the rumen microbiome and metabolic potential of Ethiopian Boran cattle **1188**
R. Van Damme, L. Nasirzadeh, W. Ayalew, T. Klingström, G. M. Tarekegn, S. Flores, E. Bongcam-Rudloff

Independent validation of Enterosignatures reveals reproducible community patterns and stress-associated assembly under porcine commercial conditions **1189**
A. Clavell-Sansalvador, I. T. Vourlaki, R. Río-López, A. Ruiz De Valbuena, I. Huerta, A. Romagosa, C. Y. Chen, J. W. Holl, A. Dalmau, Y. Ramayo-Caldas

Shotgun Metagenomic Characterization of the Rumen Microbiome in Response to the Bovaer Feed Supplement in Lactating Holstein Cows **1190**
N. Frías-Reid, R. R. Lobo, J. L. Mejía-Méndez, C. Senés-Guerrero, M. De Donato-Capote, D. E. Navarro-López

Metagenomic insights into the host–microbiome interaction for genetic mitigation of methane emissions in cattle **1191**
Z. Cai, S. Zhang, M. A. Satti, N. Saedi, E. Karaman, G. Sahana

Poster Session 72

Runs of homozygosity reveal genomic regions associated with tropical climate adaptation in tropically adapted taurine cattle **1192**
G. H. C. Borges, V. Ligori, E. R. Carrara, G. Z. Sussai, R. R. Vicentini, L. E. F. Zadra

Updated genome scan for homozygous haplotype depletion identifies a POMT2 nonsense variant causing embryonic loss and stillbirth in Normande cattle **1193**
C. Roy, A. Barbat, F. Besnard, L. Dorso, C. Escouflaire, J. Jourdain, C. Grohs, M. Boussaha, S. Minéry, M. Chambrial, D. Boichard, C. Hozé, A. Vinet, S. Fritz, A. Capitan

Population genomics of 1,060 French dairy, beef, and local cattle breeds using whole-genome sequencing-derived SNP panel **1194**
A. Molee, P. Faux, C. Grohs, C. Escouflaire, S. Fritz, D. Boichard, P. Croiseau, A. Capitan, M. Boussaha

Allele-specific methylation and parent-of-origin QTL mapping reveal potential epigenetic mechanisms underlying genomic imprinting and beef traits in Nelore cattle **1195**
J. J. Bruscadin, T. F. Cardoso, S. C. M. Niciura, W. J. D. S. D. Diniz, J. Virginio Da Silva, P. S. N. De Oliveira, J. Afonso, A. M. G. Ibelli, A. Zerlotini, G. B. Mourao, L. L. Coutinho, L. C. D. A. Regitano

Beyond SNPs: INDELs as functional drivers of feed efficiency in Nellore cattle **1196**
M. Teodoro, G. Gubiani, A. Maiorano, L. Mota, A. Cánovas, F. Baldi

Ovine hypothalamic neurons under proteostatic pressure during leptin resistance **1197**
E. Oclon, D. Zieba

The in ovo application of synbiotics may influence the humoral immune response against homologous antigens—transgenerational insights **1198**
T. Stefaniak, J. Madej, J. Bajzert, K. Bobrek, M. Bednarczyk, E. Grochowska

Homozygous haplotype enrichment/depletion mapping identified a recessive variant in ALKBH8 causing rearing-loss in Brown Swiss cattle **1199**
S. Glatthard, F. R. Seefried, A. S. Leonard, H. Pausch, C. Drögemüller, J. Jacinto, N. K. Kadri

Unravelling signatures of Red Holstein introgression and its haplotype structure in Fleckvieh cattle **1200**
J. Schröder, M. Upadhyay, N. Krattenmacher, R. Emmerling, C. Edel, D. Seichter, I. Medugorac, G. Thaller

Session 73. EGF session: Resilience of grasslands systems for sustainable livestock production

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Sturaro, Schneider, Poulopoulou - Commission(s): LFS, SG, C - Session Type: Theme session

Theatre Session 73

How farms are impacted and deal with climate change in grassland systems: the case of Occitanie dairy sheep farms in southern France **1201**
V. Colonna Ceccaldi, A. Meynadier, M. Loubière, C. Blayac, O. Patout, C. Domange

Grassland Yield and Quality in Relation to Farming System and Intensity **1202**
M. Klopčič, M. Bric, G. Šink, M. Komainda

Seasonal variation of water-soluble carbohydrates of temporary grassland in a Mediterranean agroforestry system **1203**
T. Malizzi, F. G. Cella, M. Finocchi, A. Ripamonti, E. Senatore, A. Silvi, A. Mantino, M. Mele

Rewetting a major Dutch peat region: assessing protein production under environmental policy targets **1204**
H. Van Dijk, B. Van Selm, D. Tamsma, C. Van Middelaar, S. Oosting, R. Ripoll-Bosch

Tree thinning effects on animal performance in tropical silvopastoral system **1205**
J. Pezzopane, R. Pasquini Neto, H. Brunetti, C. Bosi, P. Oliveira, A. Garcia, L. Pinho, A. Souza, G. Ramos, A. Bernardi, A. Pedroso

Role of Grasslands in Enhancing Sustainability and Product Quality in Cattle Farming. Insights from the INTAQT project. **1206**
B. Martin, E. Caumette, R. Eppenstein, F. Klevenhussen, J. F. Hocquette

Living with wolves? Cross-country differences in perceived predator constraints to agroecological grazing **1207**
A. Van Den Pol-Van Dasselaar, I. M. Jitea, A. Krause

Beyond predation Hotspots: Livestock resilience during 26 years of wolf recolonization in the French Alps **1208**
M. Virapin, S. Raniolo, G. Brunschwig, E. Sturaro

Seven New Rules for Worm Control In Sheep **1209**
N. Cotter

Effects of previous feed intensity on level of compensatory growth in growing cattle on semi-natural grasslands **1210**
L. Hessle, M. Jardstedt, J. Becker, A. Hessle

Body reserves dynamics of dual-purpose crossbred (Bos taurus × Bos indicus) cattle across successive production cycles under contrasting semi-extensive grazing farms in Cuba **1211**
B. Cormary, M. Rodríguez, V. Pérez, A. Tesnière, P. Salgado, R. Pedraza, J. Pires, N. Friggens, E. González-García

Poster Session 73

Forage quality of rewetted peat grasslands: a preliminary evaluation **1212**
J. Mačuhová, S. Thurner

Evaluations of selected effects of feeding crushed grain to suckler cow-calves on the animals' fecal indices **1213**
H. Scholz

Investigation of immune parameters, health indicators and growth of German crossbred lambs exposed to natural gastrointestinal nematode infection **1214**
R. Martin, S. Schmucker, V. Stefanski, J. Bennewitz, M. Schmid

Session 74. Resilience and Structural Change in Dairy Regions Worldwide

Date: Thursday 10 September 2026; 8:30 - 12:15
Chair(s): Cieslak, Montanholi, Kuipers - Commission(s): C - Session Type: Theme session

Theatre Session 74

Transforming Dairy Systems in APHCA Countries: Productivity, Health and Climate-Smart Innovation **1215**
Y. Montanholi, F. Teillard

Scaling up strategic investments in the dairy sector using the LSIPT WebApp: Evidence from a national genetic breeding centre in Bhutan **1216**
M. Hamon, G. Leroy, T. Yangzome Dorji, S. Norbu

Building Inclusive and Sustainable Dairy Production: Global Insights on Community-Led Transformation Models from Heifer International **1217**
D. Bhandari, K. Sah, C. Tabora

Enhancing dairy productivity in low- and middle-income countries through synergistic approaches **1218**
M. S. Muktar, C. S. Jones, B. H. Chuko, A. T. Negawo, M. B. Derseh, A. T. Gari, B. Lukuyu, E. Habte, A. Frank-Lawale

Delivering Genetic Gains for Productivity, Climate Resilience, and Low Emissions in African Dairy Systems through ILRI-Led Genomics-Based Breeding **1219**
I. Houaga, R. Mrode, S. W. Alemu, G. Gebregziabher, J. Ojango, S. Meseret, E. T. Lyatuu, C. Ekine-Dzivenu, A. Frank-Lawale

Investing in dairy for inclusive rural transformation: priorities and challenges from different regions and systems **1220**
A. Mottet, P. Ndungu

Innovations in temperate grazing dairy systems in Australia driven by precision management of pasture and livestock **1221**
F. R. Dunshea, I. Sawyer, F. Ahmadi

Production Efficiency Trends in Thai Dairy Farms through Strategic Benchmarking **1222**
P. Pattamanont, S. Khongkrapan, J. Khemsawat, B. Granzin

Poster Session 74

The natural additive Fator P included in diets of increases affinities of antibodies specific for salivary proteins of Rhipicephalus microplus ticks in beef and dairy cattle **1223**
L. Fernandes, L. Ferreira, R. Bin, I. Santos, R. Paranhos

Mitigation of enteric methane emissions by dietary essential oil supplementation in tropical feedlot systems **1224**
C. Franzon, J. Michelini, M. Dalafini, F. Oristanio, M. Marques, E. Furlan Junior, E. Magnani, L. Drouet, R. Dari, T. Da Silva, R. Branco

Session 75. Methane mitigation via animal nutrition - Part 1

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Pinotti, Ranilla García, Ottoboni - Commission(s): N - Session Type: Theme session

Theatre Session 75

Effect of 3-NOP and dietary NDF concentration on methane emission and ruminal synthesis of vitamin B12 in dairy cows **1225**
S. Lashkari, M. R. Weisbjerg, S. K. Jensen, S. Fedosov, C. W. Heegaard, A. L. F. Hellwing, P. Lund

Effects of 3-nitrooxypropanol (3-NOP) supplementation on enteric methane emissions and milk production in dairy cows fed canola meal or soybean meal **1226**
C. Benchaar, F. Hassanat, S. Terry

Effects of 3-nitrooxypropanol, nitrate, and rumen-protected fat, alone and in combination, on gaseous emissions and performance of lactating dairy cows **1227**
G. Vivares, W. Muizelaar, J. Dijkstra, A. Bannink, S. Van Gastelen

Exploring the effects of 3-nitrooxypropanol in diets varying in crude protein and starch content on methane and nitrogenous greenhouse gases emissions from dairy cows **1228**
S. Van Gastelen, H. J. C. Van Dooren, J. Faas, M. Kambara, A. Haruno, L. F. M. Tamassia, A. Bannink

Effects of feeding palmitic and stearic acids as triglycerides on milk production and methane emissions in dairy cows **1229**
S. M. Jespersen, G. Giagnoni, L. Wiking, M. R. Weisbjerg

Immunonutrition in ruminants **1230**
A. Schwarm

Effects of efficiency phenotype and forage to concentrate ratio on milk production and methane intensity in dairy cows **1231**
M. Vadroňová, P. Fant, K. Kozicka, P. Huhtanen, M. Ramin

Effect of supplementing lactating dairy cows diet with an Asparagopsis taxiformis based product on enteric gaseous emission, lactation performance, and active compound milk residues **1232**
S. Danesh Mesgaran, W. Xu, J. L. Romano-Muñoz, A. López-Juárez, A. González De Cosío-Barrón, A. Rytz, M. Bobkov, M. Coulet, E. Soussan

Effect of a dietary cinnamaldehyde–eugenol–capsicum oleoresin blend on production and methane emissions in Holstein lactating cows **1233**
C. Christodoulou, S. M. Tondini, D. J. Humphries, H. Khelil-Arfa, P. Kirton, A. K. Jones, C. Panzuti, D. Luebe, S. Stergiadis

Do cows rank similar in methane yield in first and second lactation? **1234**
M. H. Kjeldsen, T. De Evan, P. Lund, M. R. Weisbjerg

Effect of rice bran supplementation on nutrient utilization and methane emissions of beef heifers grazing native pasture **1235**
C. Ferrés-Castells, G. Fernandez-Turren

Methane emission response to feed supplements differs among cows **1236**
K. Veerkamp, M. Van Tol, B. Kemp, W. Van Straalen, A. Van Knegsel

Dietary sweet chestnut tannins decrease diarrhea incidence and litter nitrogenous gas emissions in pre-weaning holstein calves **1237**
E. Scaglia, L. Gogna, A. Antonioli, V. Sergi, L. Giagnoni, G. Gilioli, V. Caprarulo

Poster Session 75

Rumen microbial adaptation time following dietary shifts and diurnal variation post-feeding **1238**
A. A. Schönherz, S. C. H. Hansen, M. H. Kjeldsen, M. R. Weisbjerg, Z. Cai, S. J. Noel

Validation of global methane prediction equations for Austrian dairy cows under silage-based rations **1239**
M. Gierus, F. Oberhollenzer, L. Dardabou, G. Terler

Hand-held laser device as a tool to monitor relative differential enteric methane emissions in dairy cows supplemented or not with a natural feed additive **1240**
A. Silvi, E. Senatore, G. Foggi, A. Mantino, M. Mele

Effects of individual and stacked feed additives on in vitro methane production **1241**
Í. R. R. Castro, B. Hiley, O. C. Carballo, G. Scoley, S. Huws

Effects of garlic extract-attapulgite hybrid mixture on performance and enteric methane production in Hanwoo steers **1242**
R. Bharanidharan, A. A. K. Nirmal Athauda, S. H. Beak, J. Lee, H. K. Kim, A. Jo, K. H. Kim

Effects of low levels of nitrate supplementation on milk and methane production in lactating dairy cows **1243**
Y. Roman-Garcia, L. Dicks, P. Piantoni, G. Schroeder

Mitigation of methane emissions and modulation of rumen microbiome by Asparagopsis-based feed additives in Hanwoo steers **1244**
M. Miguel, M. N. Aprilliza Am, A. R. Son, S. H. Kim, Y. P. Naing, K. S. Baik, K. S. Dhia, S. Begum, Y. I. Cho, K. W. Park, T. Park, D. Lawson, S. S. Lee

Seasonal variability in the response of enteric methane emissions to 3-nitrooxypropanol in dairy cattle **1245**
M. Omirou, K. Kaikiti, J. Rodosthenous, G. Hadjipavlou, D. Sparaggis

Bovaer separation by feed particle size at two inclusion doses in dairy cows mixed rations **1246**
G. Giagnoni, M. Maigaard, C. Ohlsson, N. Walker, M. B. Jensen, M. R. Weisbjerg, P. Lund, G. A. Franchi

In vitro evaluation of the effect of plant extracts on methane production and fiber degradation in a rumen ecosystem **1247**
G. Desrousseaux, V. Noirot, A. Froidurot, P. Grimm, S. Julliand

Session 76. Improving fertility in Farm Animals

Date: Thursday 10 September 2026; 8:30 - 11:30
Chair(s): Vanselow, Kenny - Commission(s): PH - Session Type: Theme session

Theatre Session 76

Metabolomic Profiling of Dairy Cows During the Transition Period: Associations with Reproductive Outcome **1248**
L. Zambianchi, E. Schievano, G. Campion, E. Giaretta, I. Fusaro, B. Merlo, R. Colleluori, A. Formigoni, L. Mammi

Lipidomic profile of dairy cows across key reproductive timepoints and association with fertility outcomes **1249**
P. Prasinou, V. Di Giandomenico, L. Zambianchi, H. Jalal, E. Giaretta, B. Merlo, M. Giammarco, L. M. E. Mammi, I. Fusaro

Tail hair δ^{15}N identifies cows with lower calf loss and greater liveweight production in extensive beef systems **1250**
L. Prada E Silva, K. Eyre, K. Mccosker, G. Somerset

Serum microRNA Signatures Associated with Clinical and Subclinical Endometritis in Dairy Cows **1251**
S. Kreuzer-Redmer, L. Neubrand, H. Pothmann, M. Drillich, K. Wagener

Selection for Developmental Speed Skews Sex Ratios and Molecular Profiles in Bovine IVP Embryos **1252**
V. S. Baddela, T. Fersterer, R. Pöhland, F. D. A. M. Sterza, C. Ludwig, D. Becker, C. Kühn, J. Vanselow

Extender-Specific Lipidomic Signatures in Buck Semen **1253**
R. Murray, M. Hitit, M. Bodu, O. Greenwood, Z. Erdogan, S. Woldesenbet, M. R. Ugur, A. P. Cervantes, E. Memili

Reproductive performance as a pillar of pig production: interaction between parity and barn environmental parameters **1254**
C. Cintra Rodrigues, I. Bez, C. Sevillano, M. Lopes, S. Weber, L. Costa

Effect of dietary quercetin and genetic line in rabbit semi-intensive production system **1255**
D. Jordán-Rodríguez, J. Fernández-González, A. Vicente-Carrillo, P. L. Lorenzo, P. G. Rebollar, R. M. García-García, M. Arias-Álvarez

Assessment of Securidaca longipedunculata (violet tree) effect on Semen Quality and Blood Sex Hormone Levels in Indigenous Goats **1256**
K. Shai, N. A. Sebola, S. Lebelo, M. Mabelebele, F. Manyeula

Effects of maternal undernutrition on splenic white pulp morphology and immune-related metabolomic profiles in Japanese Black (Wagyu) fetuses **1257**
T. Haginouchi, Y. Suzuki, T. Gotoh

Poster Session 76

Computer-Assisted Evaluation of Different Diluents on Kinematic Parameters of Ram Semen During Liquid Storage up to 72 h at 4 °C and after 2 h of Incubation **1258**
L. Mara, F. Chessa, I. Cossu, O. Todde, C. Nassif

Effects of egg yolk and goat milk extenders on cryopreserved semen quality of West African Dwarf goats **1259**
N. A. Muhammed, T. O. Idowu, O. S. Ogundele, E. O. Adekunle, A. B. Kolade, F. A. Bello, A. A. Omoloye, M. A. Agbanimu, R. A. Ahmed, O. C. Olaniyi, V. T. Atanda, J. O. Daramola

Session 77. Carbon accounting on farms: Between standardisation and site-specific realities

Date: Thursday 10 September 2026; 8:30 - 12:00
Chair(s): Rivero - Commission(s): LFS - Session Type: Theme session

Theatre Session 77

Policy to practice: Driving farm-level change with carbon accounting and transparent Scope 3 **1260**
J. Gilliland

Carbon footprint as a key indicator of structural diversity in extensive dehesa livestock farms **1261**
A. Horrillo, P. Gaspar, A. Rodríguez-Ledesma, M. Escribano

A combined nutritional-genetic modeling approach to predict enteric methane emissions in individual and groups of dairy cows **1262**
P. Mwangi, C. Richardson, K. Grant, N. Howes, R. Jahnel, C. Baes, F. Miglior, A. Fleming, E. Kebreab, J. Ellis

Bridging the Climate-Corporate Gap: Utilizing GWP* with GWP100 for Livestock Companies' Greenhouse Gas Inventories **1263**
S. Klopatek, L. Thompson, M. Beck, S. Place

Dynamic Life Cycle Assessment of Greenhouse Gas Emissions of Live Animals in Beef Cattle Production **1264**
M. Ryynänen, S. Hietala, A. Stygar, J. Niemi, M. Pastell

Dietary carbon use efficiency, emissions, and losses in growing-finishing pigs **1265**
G. Shurson, B. Kerr, S. Trabue, D. Humphrey

Economic and greenhouse gas emissions assessment of grass silage under different management scenarios in Irish grassland systems **1266**
G. Don, M. Mcgee, L. Gallo, E. Sturaro, M. Berton, P. Crosson

Constraints on greenhouse gas emission mitigation options of dairy cow farms in Switzerland through production systems and agro-climatic zones 1267
D. Stucki, S. Ineichen, B. Reidy, J. Grenz

Exploring scenarios for integral sustainability of Dutch dairy farms towards 2030 1268
M. De Vries, A. Evers, G. Doornewaard, M. De Haan, J. Reijs, S. Jebbink, G. Migchels, P. Galama

Relevance, Variability, Availability – Evaluation of German dairy farm data for GHG accounting 1269
K. Agethen, K. Bretschneider, L. M. Hollmann

Environmental assessment of french rainbow trout production : a regional analysis 1270
S. De Montmorillon, J. Aubin, A. Tocqueville, C. Van Cuyck, J. Bonneau, M. Dupont-Nivet, S. Pouil

Poster Session 77

Advancing Harmonised Data Collection and Product-Based Greenhouse Gas Accounting in Dairy Production 1271
F. Fenger, T. Krebs, H. Knopp, H. M. Paulsen

The carbon footprint of Bonsmara cattle grazing Sourish mixed bushveld in South Africa 1272
S. M. Grobler, M. Kidson, H. T. Pule, M. M. Scholtz

Session 78. Young Pig Management and Nutrition - Part 1

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Lawlor, Trevisi, Girard - Commission(s): P - Session Type: Theme session

Theatre Session 78

Pre- and post-weaning management and nutritional strategies to increase piglet growth and health 1273
P. G. Lawlor

Delayed weaning impacts on piglet gut physiology and metabolism 1274
C. Knudsen, S. Ferchaud, M. Despeyroux, C. Lencina, N. Marty-Gasset, L. Cauquil, A. Juppeau, G. Payros, Y. Lippi, S. Combes, M. Beaumont

A fresh start: The effect of hygiene routine in the farrowing room on piglet faecal consistency, performance, and tail damage prevalence 1275
A. Middelkoop, J. Boekhorst, M. Kleerebezem, F. Molist

Pre-Weaning Supplementary Milk Enhances Post-Weaning Feeding Behaviour and Growth Performance in Piglets 1276
F. González-Solé, L. Sobrevia, L. Blavi, A. Koppenol, S. Tibble

Dietary supplementation with sodium butyrate and plant extracts to optimize the weaning process and productive outcome in piglets 1277
J. Muñoz-Grein, A. H. Checkikene, M. Á. Latorre, A. Belanche

Propionic acid–preserved grain enhances growth performance more effectively than combined butyric acid and resistant starch supplementation in weaned pigs 1278
K. R. Connolly, T. Sweeney, J. V. O'Doherty

Berry Good for the Gut: The effect of Aronia melanocarpa and Ribes nigrum Pomace Mix on Oxidative Stress and Gut Health in Weaned Pigs Challenged with Enterotoxigenic Escherichia coli F18 **1279**
A. P. Rasmussen, S. K. Jensen, A. R. Williams, K. Jerez-Bogota, C. Lauridsen

Impacts of encapsulated amino acids on growth performance, gut microbiota, and the caecal metabolome in weaned pigs **1280**
F. Correa, D. Luise, T. Chalvon Demersay, D. Guillou, P. Trevisi

Effect of increasing dietary lysine level on transcriptomic profile in pig longissimus thoracis muscle following a period with dietary protein restriction after weaning **1281**
R. Ruggeri, M. Sharma, M. Girard, P. Silacci, G. Bee, C. Larsen, A. R. Williams, J. G. Madsen

Supplementation of His and Arg during the nursery phase improves gut health in weaning piglets fed low crude protein diets. **1282**
A. J. Galindo, D. Solà-Oriol, M. Paniagua

Impact of a bioactive additive as an alternative to antibiotic growth promoters on growth performance, gut health, and inflammatory response in weaning piglets **1283**
A. J. C. Buzatto, G. Zigovski, I. C. C. Bez, M. R. R. Catoia, G. M. D. O. Júnior, P. L. D. O. Carvalho, L. B. Costa

Late lactation represents the main time-window for sow-to-piglet transmission of persistent gut strains **1284**
M. Pomies, G. Agoutin, L. Auer, A. Castinel, O. Bouchez, C. Achard, H. Quesnel, G. Pascal, S. Combes

Lactobacillus postbiotic in gestating and lactating sows: effects on sow microbiota, colostrum omics composition, litter growth and health **1285**
B. Polimeni, F. Correa, D. Luise, G. Rocchetti, A. Serra, P. Trevisi

Poster Session 78

Effect of Dietary Zinc Supplementation on Growth Performance and Health of Piglets during the Early Rearing Phase **1286**
D. Outor-Monteiro, T. Skau Nielsen, H. Maribo, M. Ramis, J. Paié-Ribeiro, V. Pinheiro

Effect of increasing the dietary valine-to-lysine ratio on growth performance of average and slow growing pigs during the weaner period **1287**
C. Larsen, D. A. Columbus, H. M. Hammon, J. G. Madsen

Effect of increasing levels of linseed expeller in nursery pig diets containing Carob meal **1288**
N. Einhardt Manzke, A. Torres, A. Balfagon, C. Vanderhaeghe, G. Mantovani, L. Hackenhaar, J. De Laat

Multi-omics characterization of sow colostrum and faecal microbiota reveals signatures associated with parity, piglet survival and growth **1289**
B. Polimeni, D. Luise, F. Correa, G. Rocchetti, M. Errico, A. Gallo, F. Bonelli, A. Serra, M. Mele, P. Trevisi

Semi-targeted metabolomics to explore potential blood biomarkers of oxidative stress in pigs using an E. coli LPS model **1290**
P. A. Madsen, K. Jerez-Bogotá, D. Vodolazska, M. S. Hedemann, C. Lauridsen

Effect of tannin of Chestnut and MGM-P on early weaning stage of piglets **1291**
Z. Yang, P. Shi, K. Wang, M. Ma, Y. Enomoto, T. Suda, J. Li

Session 79. Advancing Animal Welfare Assessment with PLF Technologies: Insights from the aWISH Project and related research - Part 1

Date: Thursday 10 September 2026; 8:30 - 12:30
Chair(s): Holinger, Maselyne, Blanco-Penedo, Van Noten - Commission(s): HW, SG, PLF, PO, P, G - Session Type: Theme session

Theatre Session 79

The aWISH vision: Improving welfare of pigs and chickens by automated monitoring of animal welfare indicators at slaughter **1292**
N. Van Noten, F. Tuyttens, Awish Consortium, J. Maselyne

Monitoring on-farm welfare by using animal-based indicators at slaughter – past and future **1293**
C. Berg

An Integrated Welfare Intelligence Platform Across the Animal Production Chain **1294**
G. Mandilaras, K. Perakis

Roadmap for a Prototype Knowledge Platform to Track European Animal Welfare Data. **1295**
J. Zemzmi, E. Caro, C. Reverté, S. Ashe, L. Amato, Y. P. Van Der Stede, A. Velarde

Experiences and expectations of pig processing plants in the aWISH project to monitor animal welfare using sensor technologies **1296**
R. Klont, M. Bouwknegt, E. Kurt, N. Kajari, J. Reixach, C. Pfeiffer, M. Lindinger, E. Klont

The Eyes & Ears project: automatic on-farm monitoring of animal health and welfare **1297**
T. B. Rodenburg, P. Llonch, E. Mainau, W. Wang, M. Coutant, S. Ntalampiras, L. Büttgen, E. D. Ellen, M. Giacobini, O. Guzhva, N. Högberg, C. Gaillard, M. Majewski, M. F. Giersberg

Using continuous sensor data on barn climate to evaluate the effect of barn climate advice on pig welfare: a Dutch case-study **1298**
K. Van Langeveld, N. Van Staaveren, N. Van Noten, T. B. Rodenburg, M. F. Giersberg, R. Klont, K. Mulder, F. A. Tuyttens

Development of a computer vision system for the assessment of swine welfare from indicators on carcasses. **1299**
Y. Seddon, F. Ferri, J. Yepez, M. Ahadi, Y. Wang, R. Ko, M. Lagoda, S. B. Ko

Interactive catalogue of sensor technologies for automated welfare assessment at pig slaughterhouses **1300**
A. Ramon-Perez, B. Forkman, X. Manteca, P. Llonch

Ensemble Machine Learning Framework for Automated Cough Detection in Pigs **1301**
K. Mladenović, M. Tomić, J. Stanojević, D. Dramićanin, B. Karaklajić, V. Vujačić, J. Sudar, N. Kajari, D. Pavlović

Validation of a Computer Vision–Based Tail-Length Measurement Algorithm for Finishing Pigs at the Slaughterhouse **1302**
C. Pfeiffer, K. Maschat, S. Kalburgi, A. Voss, C. Bonk, J. Baumgartner

Automated real-time monitoring of corneal reflex using computer vision to assess stunning effectiveness in a commercial pig slaughterhouse **1303**
J. Sanchez-Cañadó, A. Ramon-Perez, V. Garcia-Vera, J. Plà-Claver, J. Reixach, J. Canet, S. Gol, X. Manteca, P. Llonch

Time of last breath inside the stunner as an accurate proxy to necessary durations of exposure in controlled atmosphere stunning of pigs **1304**
J. Knöll, J. Gelhausen, D. Mörlein, J. Tetens, I. Wilk

Detection before occurrence: Predicting stunning effectiveness and re-stunning necessity in pigs via computer vision-based tools **1305**
K. Zavyalova, J. Knöll, I. Wilk, H. Schomburg

Poster Session 79

Validation of Best Practices to reduce tail, skin and lung lesions in pigs based on a survey with animal welfare experts **1306**
M. Fels, M. Jachens, N. Kemper

Integrating Welfare and Economic Assessment of the Weight-Detect AI System in Commercial Pig Production **1307**
M. Boimah, P. Thobe, T. Banhazi

Challenges in Establishing Ground Truth for Skin Alterations on Pig Carcasses for Training Computer Vision Algorithms **1308**
C. Pfeiffer, A. Voss, T. Heindl, A. Holzhacker, S. Kalburgi, C. Bonk, K. Maschat, J. Baumgartner

Thermal Stress Detection in Poultry Using Audio Signal Analysis and Supervised Latent Space Structuring **1309**
P. Créach, C. Merchi

Validation of a computer vision model for automated tear staining assessment in pigs **1310**
S. Verlinde, K. Van Langeveld, R. P. Angela, N. Van Noten, P. Llonch, F. Tuyttens, J. Verwaeren, J. Maselyne

An investigation into the effectiveness of an alternative one-step head to body electrocution technique using mains voltage and off-the-shelf electrodes for euthanasia of large pigs (>130kg) **1311**
C. Cole, J. Norton, M. Denicourt, C. Klopfenstein, Y. Seddon

A protocol for the assessment of (un)consciousness after stunning during slaughter of cattle **1312**
C. Berg, J. Jerlström, M. Gerritzen, E. N. Sossidou, M. L. Ianetti

Pilot insights into repeatable monthly animal welfare assessments on dairy farms **1313**
R. Wulf, J. Kleist, S. Demba, L. Bachmann

A new protocol for the assessment of (un)consciousness during slaughter without stunning **1314**
M. Milazzo, S. Rota Nodari, A. Iannetta, M. Di Monte, M. P. Podaliri Vulpiani, E. Di Benedetto, G. Matteucci, L. Torricella, M. Gerritzen, J. Maters, L. Iannetti

Gasping and gagging in pigs after CO2 stunning: indicator of insufficient stunning or part of the dying process? **1315**
J. Jerlström, V. Axberg Algotsson, C. Lindahl, C. Berg

Session 80. Free Communications on Pigs

Date: Thursday 10 September 2026; 8:30 - 12:00
Chair(s): Trevisi - Commission(s): P - Session Type: Free communications (bottom-up)

Theatre Session 80

Effect of dietary inclusion of a Gracilaria chilensis by-product on post-weaning growth and health of pigs **1316**
C. Negrini, J. Glynn, G. Gardiner, L. Giblin, P. Lawlor

Protein and fiber source and inclusion level modulate feed preference in weaned piglets. **1317**
O. Tej, J. Leskovec, M. Colom-Pellicer, C. Güell Saperas, M. Ferrando Cogollos, D. Torrallardona

Effect of dietary inclusion of a Laminaria hyperborea by-product on post-weaning growth and intestinal health of pigs **1318**
J. Glynn, C. Negrini, G. Gardiner, L. Giblin, P. Lawlor

Effects of pre- and post-weaning zinc and copper supplementation strategies on their homeostasis in plasma, intestinal mucosa and liver in pigs **1319**
J. S. Bee Tubin, J. V. Da Silva Duarte, I. Audet, D. Bueno Dalto

Characterization of a non-invasive indicator for LPS-induced inflammation in the saliva of pigs fed high or low fiber diets **1320**
M. Sciascia, M. Cavalleri, S. Görs, A. Vernunft, H. Reyer, M. Oster, L. Moscovice, K. Wimmers, J. Zentek, S. Dänicke, S. Kersten, C. Metges

Serum magnesium and protein profiles in domestic pigs versus wild boars – possible links to tail biting behaviour **1321**
K. Büttner, K. Westhoff, M. Lierz, C. Irena

Haematopoietic traits in indigenous and modern pig breeds are modulated by housing system and developmental stage **1322**
K. Kapoor, M. Oster, H. Reyer, C. Metges, N. Trakooljul, S. Ponsuksili, E. Muráni, K. Wimmers

Improving meat quality in local Krškopolje pig breed using advanced optimum contribution selection approach **1323**
K. Poklukar, M. Čandek-Potokar, M. J. Mercat, S. Taussat, M. Škrlep

Computed tomography demonstrates high repeatability when compared to chemical analysis when measuring pork carcass composition **1324**
C. A. Vaz Do Amaral, F. Anderson, M. T. Corlett, M. Trezona, A. Williams, L. Pannier, G. E. Gardner

A standardized workflow for reproducible pig microbiome profiling across laboratories **1325**
S. O. Enokela, T. Yergaliyev, K. Flisikowski, S. C. Hornburg, H. Reyer, J. Tetens, K. Wimmers, J. Zentek, A. Camarinha-Silva

Improving weaning piglets performance and blood immune parameters by supplementing iron through a milk cup system during lactation **1326**
L. Sobrevia, F. González-Solé, L. Blavi, A. Koppenol, S. Tibble

It's not just about feeding. Fatty acid composition of the local Angler Saddleback pig **1327**
A. Olschewsky, M. Krieger, D. Hinrichs, A. Sünder, D. Mörlein

Poster Session 80

The influence of the sex of fattening pigs on the content of vitamins A and E and cholesterol in the longest dorsal muscle **1328**
K. Dobiesz, W. Kozera, G. Żak, M. Szyndler-Nędza, A. Mucha, K. Karpiesiuk

Sensory properties and mechanical parameters of the longest dorsal muscle in fattening pigs depending on sex **1329**
K. Dobiesz, W. Kozera, G. Żak, M. Szyndler-Nędza, A. Mucha, K. Karpiesiuk

Evaluation of handheld near infrared spectrometers (NIRS) for prediction of fat quality traits at slaughter **1330**
Z. Bodor, Y. Chen, D. Mörlein

GlasSchwein: Development of predictive models for parameters of meat quality and quantity along the pork value chain **1331**
F. Heinrich, Y. Chen, Z. Bodor, D. Mörlein, R. Hölscher, V. Beck, S. Retz, A. O. Schmitt

Effect of turmeric supplementation on growth performance, nutrient digestibility, and blood parameters in growing pigs subjected to heat stress **1332**
L. Pu, S. Shanmugam, J. H. Kim, K. Lee, K. Han, I. H. Kim

Effect of increasing level of L-carnitine for lactating sows on sow body mobilization, milk composition, litter growth and sow plasma cytokines **1333**
C. Larsen, D. Nguyen, K. L. Mønsted, T. Bruun, A. Strathe

Effect of increasing level of extruded linseeds for lactating sows on changes sow body mobilization, litter gain, milk composition and plasma cytokines. **1334**
E. Christensen, C. Larsen, K. Mønsted, D. Nguyen, S. Jensen, T. Bruun, A. Strathe

Lactation feed intake and feed intake relative to body weight are associated with litter weaning weight across sow parities **1335**
C. Mulvenna, M. Sungirai, R. Muns

E. coli and early mortality: Association of MUC4, MUC13 and FUT1 parental genotypes with pre-weaning mortality in a commercial pig population **1336**
J. De Kort, J. Depuydt, K. Hooyberghs, S. Janssens, N. Buys, W. Gorssen

Session 81. Ethics, Data Management and Data Standardization in PLF with the future of AI

Date: Thursday 10 September 2026; 8:30 - 11:45
Chair(s): Foy, Gautier - Commission(s): PLF - Session Type: Theme session

Theatre Session 81

Rethinking AI for Animal Welfare: Framing, Misinformation and Ethics **1337**
M. A. Von Keyserlingk, K. Sheng, B. Foris, D. M. Weary

The Digital Ethogram: A Multimodal, High Time-Resolution Representation of Animal Behaviour **1338**
T. D. Parsons, D. Foy

Health and Welfare Commission perspectives on AI and farm animal welfare **1339**
L. Boyle

From data streams to breeding values: developing and harmonizing novel phenotypes for sustainable livestock genetic improvement **1340**
L. F. Brito

Data standardisation for welfare and genetics evaluations **1341**
A. Granados Chapatte, S. Orlandini

European Network on Livestock Phenomics: an international initiative aimed at promoting and resourcing advanced phenotyping in livestock **1342**
G. Schiavo, S. Bovo, J. Maselyne, T. Norton, L. Fontanesi, &. Eu-Li-Phe Consortium

SENSTARA: Advancing sensor-based indicators of animal resilience, health, and welfare in precision livestock farming **1343**
D. Foy, J. M. Gautier, B. Foris, C. Morgan-Davies, L. Dale, P. P. Nielsen, G. A. Franchi, X. Díaz De Otálora

Poster Session 81

Data preprocessing transparency as a requirement for robust sensor based livestock indicators **1344**
G. Franchi, B. Foris, J. M. Gautier, C. Morgan-Davies, L. M. Dale, P. P. Nielsen, X. Diaz De Otálora, D. Foy

Session 82. Advances in feed production and conversion efficiency and small ruminant nutrient utilization

Date: Thursday 10 September 2026; 8:30 - 11:45
Chair(s): Schmid, Cannas, Steinhoff-Wagner - Commission(s): SG, N - Session Type: Theme session

Theatre Session 82

Effect of milk replacer formulations on goat kids' growth performance and small intestinal development. **1345**
K. Capdevila Ospina, F. Zamuner, B. Leury, A. Cameron, K. Digiacomo

Impact of Colostrum and Serum Derived IgG with Cream or Vegetable Oil on Growth and Immune Status of Dairy Goat Kids **1346**
S. J. Mabjeesh, Y. Wein, Y. Ashbel, C. Sabastian, R. Komakech, R. Tadmor-Levi, T. Theresa Casey, C. Ferreira, N. Argov-Argaman

Effect of breed on rumen microbiota in lambs treated with aqueous extract of Tithonia diversifolia as an additive **1347**
O. T. Barreto Cruz, D. C. Mogollon Vergara, R. D. Castañeda Serrano, J. C. Henao Zambrano, M. A. Ospina Barrero

Replacing corn grain with dried sugar beet meal in fattening goats: effects on feed efficiency, gastrointestinal microbiota and plasma metabolomic profile **1348**
M. Penati, F. J. Giráldez, M. Dehnavi, P. Cremonesi, F. Biscarini, F. Ceciliani, C. Lecchi, A. Martín, M. J. Ranilla, M. Hosseini Ghaffari, L. Abdennebi-Najar, S. López, S. Andrés

Feeding hydroponic barley sprouts to early lactation dairy goats: consequences for intake, nutrient utilization, milk performance, and immune markers **1349**
S. J. Mabjeesh, R. Komakech, Y. Wein, C. Sabastian, H. Haim Tagari

Milk and plasma multi-omics: insights into feed conversion and residual intake in dairy goats. **1350**
J. Kirkham, F. Zamuner, A. Cameron, N. E. Doomun, D. De Souza, B. Leury, K. Digiacomo

Associations of residual feed intake with growth performance, body size, carcass traits, meat quality and blood parameters in growing Naimi lambs **1351**
A. El Awad, O. Alsheblak, M. Eltemamy, A. Kullan, E. Neumann, S. Alalawi, T. Alketbi, S. Matarneh, H. Alshamsi, S. Alalawi, A. Alkaabi, A. Alkuwaiti, D. Alketbi, D. Albahar, T. Alkaabi, J. Loor, A. Elolimy

How diet can improve lamb muscle lipid profiles and rumen microbiome **1352**
B. Fuchs, D. Dannenberger, L. Perkins, N. Scollan

The supply with branched chain volatile fatty acids during the transition period and the lactation of dairy ewes. **1353**
A. Foskolos, A. Gomez, D. Kleinsdchmit, E. Skepetari, V. Galanis, N. Vasileiou, E. Malisiova, M. Alexandraki, D. Kantas

Comparing weaning strategies: growth performance of dairy goat kids in intensive systems **1354**
K. Capdevila-Ospina, F. Zamuner, B. Leury, A. Cameron, K. Digiacomo

Assessment of feeding rations in small ruminant farms using the Small Ruminant Nutrition System **1355**
G. Batikas, S. Dokou, A. Zemou, S. Vouraki, G. Arsenos

Poster Session 82

Exploring the ruminal metabolome of sheep supplemented with essential oils **1356**
E. Rodrigues Cavalheiro Junior, O. Pricila Prado Calixto, E. Jorge Pilau, R. De Oliveira Venci, R. Martin Do Prado

Sex-specific effects of local and imported alfalfa on performance, intake, digestibility, morphology, methane emissions, and nitrogen balance in Korean crossbred goats **1357**
K. Kwan-Woo, L. Eun-Do, K. Hyo-Jin, B. Sung June, T. Byamungu Mayange

The lactation and seasonal effects on glucose utilization in dairy goats under high ambient temperature **1358**
S. Thammacharoen, C. Chitueakul, K. Yutthaworawit, P. Bunkhan, S. Veeraman, N. Saipin, N. Chaiyabutr

Session 83. Artificial intelligence applications in poultry farming systems

Date: Thursday 10 September 2026; 8:30 - 10:15
Chair(s): Druyan, Odintsov Vaintrub - Commission(s): PO - Session Type: Theme session

Theatre Session 83

Technologies for Individual Sensing of Poultry in Commercial Hen Houses **1359**
V. Bloch, M. Ross, A. Haron, Y. Heler, A. Godo, I. Halachmi, S. Druyan

Seeing the Unseen: AI-Powered Detection of Feeding, Drinking, and Resting Behaviors in Broiler Production **1360**
M. Alexy, G. Toth

Investigation on chickens' escape behaviour in the free-range area related to the presence of birds of prey **1361**
L. Hofmann, A. Langehennig-Peristenidou, N. Kemper, N. Volkmann

Automated Poultry Behavior Monitoring via Hybrid Multi-Object Tracking and Learned Visual Descriptors **1362**
B. Ramon, J. Tarres, M. Piles, C. Antens

From climate projections to building adaptation: a decision-support tool for heat stress in French poultry farming **1363**
Y. Guyot

Direct monitoring of Salmonella typhimurium using smartphone CL imaging **1364**
G. Shtenberg, N. R. Nirala

Poster Session 83

Dual-Mode Portable Biosensing Platform for Rapid and Sensitive Detection of Salmonella typhimurium **1365**
G. Shtenberg, S. Arumugam

Session 84. Impact of early life nutrition on growth physiology and carcass characteristics of livestock.

Date: Thursday 10 September 2026; 10:45 - 12:15
Chair(s): Kenny, Keogh - Commission(s): PH - Session Type: Theme session

Theatre Session 84

Effect of enhanced early life nutrition on gene expression profiles of key metabolic tissues in Holstein Friesian bull calves **1366**
K. Keogh, S. Coen, P. Lonergan, S. Fair, D. Kenny

The first feeding matters: effects of passive immunity transfer on growth performance in dairy-beef calves under practical field conditions **1367**
S. Wiedemann, E. Thesing

Effect of post-weaning or pre-finishing concentrate supplementation at pasture on growth and carcass characteristics of early-maturing dairy-beef steers **1368**
J. Mcmorrow, A. K. Kelly, M. Mcgee, D. A. Kenny

Effects of nutrition and methane-suppressing feed additives on plasma metabolites of pre-weaned replacement Holstein heifers **1369**
O. Cristobal Carballo, S. O'Callaghan, S. A. Goldansaz, T. Yan, G. Scoley

Effect of dietary supplementation in Rubia Gallega calves assessed by ultrasound measurements **1370**
C. Montes, S. Crecente, C. García, R. Alonso, T. Moreno

A survey of dairy-beef calf management practices pre- and post-weaning, and post-turnout to pasture on Irish commercial farms **1371**
R. R. Male Here, M. Mcgee, P. Smith, T. Bourke, J. Smyth, S. Reilly, E. O'Riordan, D. Kenny, C. Mcaloon, B. Earley

Poster Session 84

Umbilical Cord Blood Profiling at Birth as a Predictor of Early Growth in Piglets **1372**
A. Solà-Navarro, E. Huenul, P. Salgado-López, J. F. Pérez, S. M. Martin-Orúe

Effects of maternal undernutrition on cardiac mitochondrial DNA (mtDNA) abundance and the cardiac transcriptome in Japanese Black fetuses **1373**
R. Yamamoto, T. Haginouchi, S. Takagi, T. Gotoh

Effects of maternal undernutrition on binucleate cell abundance and gene expression in the placenta of Wagyu (Japanese Black cattle) **1374**
S. Takagi, T. Haginouchi, R. Yamamoto, T. Gotoh

Tributyrin supplementation reduces diarrhea frequency and severity in preweaning calves **1375**
A. Vigh, M. Müller, V. Thierer, J. Guyader

Effect of early life high nutrition on hepatic metabolism, gene expression, and DNA methylation in beef cattle **1376**
S. Muroya, A. Saito, K. Ojima, T. Gotoh

Session 85. Enhancement of GxE methodologies in animal breeding

Date: Thursday 10 September 2026; 14:15 - 18:00
Chair(s): Strucken, Pszczola - Commission(s): G - Session Type: Theme session

Theatre Session 85

Estimation of genetic heterogeneity of variance (environmental sensitivity) of milk yield traits and somatic cell count to predict resilience of dairy cattle **1377**
M. Haile-Mariam, M. Khansefid, M. Goddard, G. Nieuwhof, A. Gilmoure

Deriving environmental variability indicators from herd-level milk production by calendar date for reaction norm models **1378**
R. Shi, N. C. Friggens, J. I. Ohlsson, T. Klingström, M. H. Pinard-Van Der Laan

Integrating satellite environmental proxies to optimise genotype-by-environment interaction assessment for weaning weight in Namibian pasture-based beef systems **1379**
S. Vanvanhossou, S. König

Population reaction norms of three German dairy cattle populations regarding heat stress **1380**
A. K. M. Neufeldt, V. P. Haas, J. Bennewitz

Genetic analysis on heat tolerance of fertility traits in Canadian Holstein cows **1381**
G. R. Dodd, F. S. Schenkel, C. F. Baes, F. Malchiodi, C. Richardson, F. Miglior

Phenotypic analysis of heat stress effects on enteric methane emissions in Holsteins **1382**
B. Amini, G. Dodd, C. Baes, F. Schenkel, C. Richardson, F. Malchiodi, F. Miglior

Genotype by environment interactions for methane emissions of dairy cows fed 3-nitrooxypropanol **1383**
A. Van Breukelen, S. Van Gastelen, B. Gredler-Grandl, R. Veerkamp, Y. De Haas

Towards a resilience selection index capturing health, longevity and heat tolerance in three German dairy breeds **1384**
F. Keßler, J. Bennewitz

Recursive model approach to define nitrogen use efficiency in Holstein dairy cows **1385**
R. E. Jahnel, L. R. Schaeffer, L. M. Alcantara, B. O. Makanjuola, A. Flemming, F. S. Schenkel, F. Miglior, C. F. Baes

A New Multivariate Index for Resilience Selection in the Nelore Breed **1386**
V. A. Ligori, L. F. C. Araújo, G. H. C. Borges, L. E. F. Zadra, J. N. S. G. Cyrillo

Genomic Insights into Genotype × Feed Interactions for Feeding Behaviour, Efficiency and Carcass Traits in Different Pig Breeds **1387**
M. F. Bellersen, E. Jonas, I. Brinke, A. Kiefer, E. Tholen, C. Große-Brinkhaus

Deep phenotypes of growing Charolais cattle divergent in residual feed intake fed two contrasting diets **1388**
H. Nguyen-Ba, A. Van Der Linden

Environmental and Spatial Drivers of Genetic Variation in the Rubia Galega Cattle **1389**
N. Mejuto-Vázquez, R. Rodríguez-Bermúdez, P. Martínez, M. Hermida

Poster Session 85

Effect of temperature and humidity index on the performance of hyperprolific sows at first service **1390**
L. Espinoza-Aguirre, J. Romo-Rubio, J. Romo-Valdez, J. Portillo-Loera, A. Romo-Valdez, U. López-Arroyo, J. Uriarte

Estimation of genetic parameters for egg weight across the laying cycle in hens **1391**
M. Sanchez-Diaz, N. Ibañez-Escriche, L. Varona, D. López-Carbonell, D. Cavero, C. Casto-Rebollo

Session 86. Genetics and epigenetics in cattle: different approaches to study stressful events

Date: Thursday 10 September 2026; 14:15 - 18:00
Chair(s): Cesarani, Kiefer - Commission(s): C, P, G - Session Type: Theme session

Theatre Session 86

(Epi)genomic regulation of phenotype diversity and plasticity in cattle **1392**
V. Baddela, J. Vanselow, G. Moreira, C. Charlier, D. Becker, G. Plastow, C. Klein, C. Kühn

Exploring blood methylome differences in dairy cow breeds under feed restriction **1393**
G. Costa Monteiro Moreira, J. A.a. Pires, V. Costes, F. Ali, H. Jammes, H. Kiefer

Environmental modulation of blood DNA methylation in Jersey cattle with shared genetic background **1394**
G. Sahana, V. Costes, E. Karaman, R. B. Stephensen, C. Patry, M. S. Lund, H. Kiefer, Z. Cai

Intergenerational and transgenerational match/mismatching effects of ancestor calving months on lactation curves in Simmental cattle **1395**
N. P. P. Macciotta, L. Degano, D. Vicario, C. Dimauro, A. Cesarani

Impact of late gestation heat stress on progeny's health in dairy cows **1396**
E. Vanbergue, G. Costa Monteiro Moreira, L. Brun-Lafleur, D. Plouzin, B. Vaillant, V. David, M. Brochard

Epigenome-wide association of DNA methylation with phenotypic traits and environment in French Holstein cows **1397**
A. Asset, V. Costes, G. Potier, M. P. Sanchez, F. Besnard, C. Fouere, S. Fritz, C. Patry, G. Foucras, H. Jammes, C. Richard, V. Gelin, L. Le Berre, A. De Paula Reis, D. Boichard, C. Le Danvic, G. Costa Monteiro Moreira, D. Makowski, H. Kiefer

Seasonal investigation of circulating microRNAs in two Sicilian cattle breeds to evaluate the response to heat stress **1398**
S. Tumino, A. Antoci, M. Carlentini, G. Chessari, A. Criscione, S. Bordonaro, D. Marletta

Seasonal effects on bull sperm-borne sncRNA profile **1399**
P. Dey, V. Costes, A. Bonnet, C. Le Danvic, E. Sellem

Changes over time, individual variability and environmental influence on blood cell counts in healthy heifers **1400**
P. Martin, D. Descamps, A. Bachelet, E. A. Richard, R. Lefebvre, V. Costes, F. Ali, G. Costa Monteiro Moreira, H. Jammes, C. Ferret, S. Riffault, F. Blanc

Diversity of Toll signalling pathway adaptors as a source for breeding for health traits in Czech Red Pied cattle **1401**
K. Novák, K. Samaké, T. Valčíková

Dynamics of sheep sperm sncRNAs during maturation, from testis to ejaculated sperm **1402**
I. Bourassi, V. Costes, L. Jouneau, A. Frambourg, A. Chauveau, P. Chavatte-Palmer, E. Sellem

Age, genetics, laying intensity, and housing conditions affect DNA methylation of the oxytocin receptor in female chicken **1403**
C. Reimer, S. Weigend, C. Klein

Poster Session 86

The effect of ambient temperature during first 10 days after parturition of female calves on their milk production during the first lactation **1404**
V. Tančin, L. Mačuhová, M. Uhrinčať, M. Vršková, J. Mačuhová

Prenatal thermal environment of calves and their milk production and composition in first lactation **1405**
L. Mačuhová, V. Tančin, M. Uhrinčať, M. Vršková, J. Mačuhová

Genetic correlations between clinical mastitis, metritis and ovarian cysts in Polish HF cows **1406**
P. Topolski, W. Jagusiak, T. Suchocki

Transcriptomic analysis to identify genes involved in physiological and immune responses to heat stress challenges in Romanian Holstein lactating cattle **1407**
D. Gavojdian, V. M. Ber, A. E. Mizeranschi, M. Mincu-Iorga, I. Nicolae, D. E. Ilie

Hormonal induction enhances functional differentiation in bovine mammary organoids **1408**
E. Mussard, S. Belvederesi, C. Kjeldgaard Larsen, M. Ladefoged Kjelsgaard, L. Bach Larsen, N. Aagaard Poulsen, S. Purup

Genome-wide DNA methylation profiling in a German Black Pied Cattle trio **1409**
A. C. Schmidt, G. A. Brockmann, E. M. Strucken

Session 87. The role of multifunctional and extensive livestock systems in enhancing rural development and ecosystem services

Date: Thursday 10 September 2026; 14:15 - 17:15
Chair(s): Poulopoulou, Pauler - Commission(s): LFS - Session Type: Theme session

Theatre Session 87

Navigating the Promise and Pitfalls of Phytochemically Diverse Pastures for Multifunctional and Sustainable Livestock Systems **1410**
A. Serkan

Agroecological characterization of alpine pastures from visible to invisible: linking pasture use, vegetation, soil chemistry, and microbial communities. **1411**
S. Raniolo, C. Pornaro, E. Basso, S. Da Re, A. Ceppatelli, L. Giagnoni, A. Squartini, E. Sturaro

Integrating locally adapted legumes into multifunctional and extensive Mediterranean livestock systems **1412**
I. Poulopoulou, P. Kechagia, T. Hadjigeorgiou, P. Bebeli, I. Hadjigeorgiou

Western Italian Alps are losing upland cheese production **1413**
M. Coppa, C. Costamagna, L. M. Battaglini

Added value of grassland based dairy farming systems: the Trentingrana PDO production in Eastern Italian Alps. **1414**
A. Ceppatelli, S. Da Re, M. Berton, E. Benedetti Del Rio, S. Raniolo, E. Sturaro

Site-adapted farming systems in mountain regions: a synthesis of key characteristics, transformations and challenges **1415**
M. K. Schneider, C. M. Pauler

Lamb meat production in marginal areas: a comprehensive carbon footprint assessment accounting for soil carbon sequestration **1416**
E. Sabia, C. Pacelli, A. Di Trana, R. Paolino, A. Coppola, C. Cosentino, L. Vignozzi, A. Braghieri

Effect of breed on the health and welfare of semi-extensively reared dairy goats in Greece **1417**
A. Zemou, S. Vouraki, G. Batikas, A. Gelasakis, G. Banos, G. Arsenos

Poster Session 87

Adoption of regenerative management practices in Mediterranean Dehesa Livestock Systems and their contribution to ecosystem services **1418**
P. Gaspar, A. Horrillo, A. Rodríguez-Ledesma, M. Escribano

Multifunctional extensive small ruminant farming in Amorgos island (Greece): implications for rural development and ecosystem services **1419**
A. Kominakis, M. Goliomytis, M. Koveos, I. Hadjigeorgiou

Effects of Pasture Diversification Strategies on Milk Production in Dairy Cows **1420**
L. Carmona-Flores, M. Bionaz, D. E. Prado-Tarango, K. La Terra, J. Cruickshank, S. Ates

Session 88. Resilient grazing and forage production, coping with environmental challenges in dairy production

Date: Thursday 10 September 2026; 14:15 - 17:45
Chair(s): Giagnoni, Valldecabres - Commission(s): C, N - Session Type: Theme session

Theatre Session 88

Towards a New Selection Index for Holstein Cattle in Pasture-Based Production Systems: Stakeholder Perspectives from a Survey **1421**
A. Breiholz, N. Volkmann, S. Voßgerau, D. Hinrichs, N. Kemper, G. Thaller, N. Krattenmacher

Emerging practices and perceptions of regenerative agriculture across pioneering Dutch dairy farms **1422**
J. Threels, E. Bokkers, E. De Olde

The potential of grass biorefinery on dairy farms **1423**
M. Hoogterp, A. Klop, S. Jebbink, A. Evers, J. De Boer, G. Van Duinkerken

Winter grazing by dairy cows: a viable solution for climate change adaptation **1424**
V. Brocard, D. Benoit, C. Caraes, S. Schetelat, G. Trou, E. Tranvoiz

Adapting Dairy Cattle Grazing Systems to Climate Change: The Role of Agroforestry **1425**
M. Mele

Herbage mass and pasture allowance affect grazing behavior more than milk production in dairy cows grazing polyphytic pasture in southern Chile **1426**
R. G. Pulido, I. Calvache, E. Herrera, J. P. Keim, O. A. Balocchi

Milk urea concentration ranges suitable as indicators of nitrogen utilization in grazing dairy cattle **1427**
M. Mangwe, C. Reed, R. Bryant, S. Davis, G. Scott, C. Phyn, D. Pacheco

Effect of increasing lucerne-to-maize silage proportion in diets on performance of dairy cows **1428**
S. Hu, R. Delagarde, N. Edouard, Y. Huang

Co-ensiling whole crop corn with increasing percentages of common beans (Phaseolus vulgaris) **1429**
M. Hünerberg, J. Hummel

Degradation Kinetics of Forage Monocultures and Multispecies Swards Harvested at Two Maturity Stages **1430**
R. Valencia, C. Reynolds, J. Hammond, L. Crompton

Red clover in grass silage-based dairy systems: A meta-analysis **1431**
P. Huhtanen, G. Baduge, M. Vaga, S. Krizsan

Poster Session 88

A comparison of Good Agriculture Practices (GAPs) for sustainable dairy farming in South Africa with the RISE 3.0 (Response-Inducing Sustainability Evaluation) tool **1432**
T. Blignaut, E. Van Marle-Köster, H. Meissner

AgroServ: an integrated multi-RI platform supporting agroecological transition in cattle production **1433**
R. Baumont, D. Baldo, M. Boër, S. Dramé, P. Florent, H. Ibrahim, R. Pieruschka

Exploration of resilience metrics in grazing dairy cows **1434**
A. I. Trujillo, A. L. Astessiano, M. Regueiro, E. Jorge-Smeding

Resilience indicator and productive performance in a commercial grazing dairy farm **1435**
A. I. Trujillo, M. Regueiro, E. Jorge-Smeding, A. L. Astessiano

Effect of incorporating Bromus valdivianus Phil. on the nutritive value of a mixed pasture during the spring–summer season in southern Chile **1436**
R. G. Pulido, I. Calvache, B. Barría, C. Asenjo, J. P. Keim, O. A. Balocchi

Polyphenol oxidase activity, phenolic concentration and utilisable crude protein in red clover (Trifolium pratense L.) accessions **1437**
G. Baduge, M. Vaga, S. Krizsan

Winter grazing or bale haylage fed indoors for pregnant heifers: growth performance and synthesis of welfare and behavioral indicators **1438**
V. Brocard, D. Fouvez, G. Trou, S. Schetelat, D. Benoit, E. Tranvoiz, M. Le Guenic

Chemical composition, in vitro digestibility, and methane production of selected fodder trees in late summer **1439**
E. Manzocchi, J. Botzas-Coluni, A. Manoukians, M. Probo, M. Terranova, P. Mariotte

Session 89. Methane mitigation via animal nutrition - Part 2

Date: Thursday 10 September 2026; 14:15 - 17:30
Chair(s): Pinotti, Ranilla García, Ottoboni - Commission(s): N - Session Type: Theme session

Theatre Session 89

Agolin and Polygain Supplementation Reduces Methane Production Without Affecting Blood Metabolites in Grazing Sheep Under Commercial Farm Conditions **1440**
B. Z. Tunkala, K. Anderson, M. Flavel, I. Sawyer, R. Eckard, F. Dunshea, S. S. Chauhan

Modifying aspects of ruminal fermentation to mitigate enteric methane generation in goats through the use of saponin- and tannin- rich plant sources - A meta-analysis. **1441**
E. Malematja, K. Daniel, M. Mabelebele, J. W. Ng'Ambi

Effects of individual and combined feed additives on ruminal in vitro fermentation characteristics. **1442**
B. Hiley, Í. R. R. Castro, S. Huws, K. Theodoridou

Assessment of some Mediterranean shrubs by in vitro studies: total gas production and CH4, CO2, H2, O2, N2 profiles **1443**
A. Cabiddu, B. Solinas, G. Moniello, P. A. Ruiu, G. M. Marrosu, M. Decandia, M. Acciaro, V. Giovanetti, M. G. Serra, M. Niolu, S. Rodrigo, G. Moreno, E. Sales-Baptista, A. Oliveira, M. I. Ferraz De Oliveira

Dose-Dependent Modulation of Methane Production, Rumen Fermentation, Digestibility and Rumen Microbial Community by L-Carvone: An in vitro Study **1444**
H. Jalal, L. Pompei, M. Giammarco, M. Irfan Malik, S. Akram, C. Chaves Lopez, M. Zeeshan Akram, F. Ghiaccio, R. Colleluori, I. Fusaro

In Vitro Assessment of Eucalyptus and Ginger Essential Oils on Methane Production in Rumen Fermentation **1445**
F. Ghiaccio, A. Federiconi, V. Piensi, V. Palanca, R. Colleluori, L. Zambianchi, P. Parazza, A. Formigoni, A. Palmonari

In vitro screening of potential synergistic combinations of garlic, cinnamon and oregano to decrease rumen methanogenesis **1446**
A. H. Chekikene, J. Muñoz-Grein, M. Mireaux, A. Belanche

In vitro screening of succinogenic bacteria and dicarboxylic acids as alternative electron sinks during bromoform-mediated methanogenesis inhibition **1447**
L. Gonzalez-Chappe, A. Daudet, P. Alvarez-Hess, R. Tognelli, A. Pittaluga, A. Relling

In vitro ruminal digestibility of bay laurel (Laurus nobilis L.) essential oil at different concentrations **1448**
A. Maggiolino, N. Parabita, G. Incampo, G. De Mastro, G. Basile, C. Ruta, P. De Palo

How carbonate based buffers and magnesium based buffers affect methane production in a rumen simulated environment **1449**
B. Naughton, O. A . Demehin, I. Hodge, P. Quille, B. Wenner, S. O Connell

Effect of hydroponic barley fodder-containing diets on methane production and rumen fermentation in dairy cattle: an in vitro assessment **1450**
E. Pacifico, M. Terranova, S. Amelchanka, M. Senese, P. Premarajan, M. Niu, L. Pinotti

Session 90. In vitro methodologies for ruminant and non-ruminant nutrition, including comparison with in vivo & ex vivo

Date: Thursday 10 September 2026; 14:15 - 15:45
Chair(s): Kar, Stergiadis - Commission(s): N - Session Type: Theme session

Theatre Session 90

Barrier protective effect of single-malt distillery-derived Lactobacillus postbiotic **1451**
O. A. Demehin, M. Ryan, A. Dowley, S. O Connell

Milk oligosaccharides shape the gut mucosal barrier in vitro in suckling rabbits **1452**
M. Rumeau, M. Beaumont, C. Lencina, E. Jones, L. Cauquil, S. Combes, C. Knudsen

Curcumin loaded liposomes ameliorates DSS-induced colitis in mice: in vitro and In vivo studies **1453**
L. L. La Min, K. Adhimoolam, T. Min

Ensiled forages modulate rumen fermentation and microbiome in lambs **1454**
A. Chaudhry

Linking in vitro methane yield with rumen fermentation patterns and milk quality traits during the transition period **1455**
R. El Hawat, D. Giannuzzi, S. Massaro, S. Schiavon, S. Pegolo, A. Cecchinato, F. Tagliapietra

Extracellular vesicles from low- and high-virulence Streptococcus uberis strains differentially regulate bovine neutrophil viability and inflammasome activation in vitro **1456**
M. Penati, O. Balbi, Y. Dadi, G. Salvi, R. I. Lazar, N. C. Cirone Silva, C. Lecchi, F. Ceciliani, L. G. De Matos

Poster Session 90

A botanical and organic acid blend protects intestinal cell viability and reduces heat stress-induced oxidative stress across human, porcine, and avian in vitro models **1457**
F. Ghiselli, A. Toschi, B. Tugnoli, E. Grilli

Exploring the combined effects of plant extracts, tannins, and saponins on cecal fermentation in weaned piglets using consecutive batch culture incubations **1458**
J. Muñoz-Grein, A. H. Checkikene, M. A. Latorre, A. Belanche

Dose-Response Effects of Isoacids Supplementation in Dry Cow Diets: Impacts on Microbial Nitrogen and Fiber Fermentation **1459**
R. Bevilacqua, D. H. Kleinschmit, A. Gomez, M. T. Socha

The effects of supplementation with the natural additive Fator P on feeding of Rhipicephalus microplus parasite larvae. **1460**
L. Fernandes, L. Ferreira, R. Bin, I. Santos, R. Paranhos

Session 91. Nutri-omics/Feed Omics in reference to animal health and welfare.

Date: Thursday 10 September 2026; 16:15 - 17:45
Chair(s): Kar, Kreuzer-Redmer - Commission(s): N, HW - Session Type: Theme session

Theatre Session 91

Effect of fermentation of field pea grains with Companilactobacillus kimchii on the microbiome in pigs using metagenomics and metaproteomics **1461**
F. Quinger, N. Klein, A. Camarinha-Silva, M. Rodehutscord, J. Seifert

Metabolomic responses of porcine gut organoids to Escherichia coli **1462**
M. Du Teil Espina, H. Fijten, B. Han, M. Vrieling, S. Van Hemert

A transcriptomic approach to study the effects of reducing the dietary balanced protein level on small intestine metabolism of slow-growing broilers **1463**
A. E. P. Mary, J. Gulmann Madsen, A. R. Williams, T. A. Woyengo

Untargeted metabolomics in urine and milk reveals coordinated nitrogen related metabolic responses to dietary protein degradability in dairy cows **1464**
M. Errico, A. Catellani, F. Froldi, M. Moschini, G. Rocchetti, A. Gallo

Dietary vitamin D_3 dose-dependently modulates gene expression in peripheral blood mononuclear cells of dairy cows following an intramammary immune challenge **1465**
G. Costa Monteiro Moreira, G. De Aguiar, Y. Martel-Kennes, C. Silvestri, D. E. Rico

Functional diversity of cannabinoid receptors in the Czech Red Pied and Czech Red cattle **1466**
K. Novák, T. Paulová, E. Pěchoučková

Poster Session 91

Effect of dietary Lactobacillus Plantarum TWK10 on growth performance, nutrient digestibility, blood profile and gut microbiome in beagles **1467**
S. Y. Jang, K. Lee, K. Das, L. Pu, I. H. Kim

Integrative Genomic and Molecular Modeling Analyses Elucidate the Structural and Functional Impact of the GCKR P446L Variant in Type 2 Diabetes **1468**
M. J. Jang, R. K. Pathak, T. H. Min, Y. J. Seo, C. Lim, J. M. Kim

Ensemble Stacking Model Based Integration of Omics Data Uncovers Dynamic Biological Mechanism Landscape and Prognostic Factors of Sleeve Gastrectomy in Morbid Obese **1469**
Y. J. Seo, M. J. Jang, C. Lim, J. M. Kim

The effect of reduced protein diet on epigenetic changes in muscles of Krškopolje pigs **1470**
K. Poklukar, M. Škrlep, M. Čandek-Potokar, M. Englund, C. Guerrero-Bosagna, F. Pértille

Session 92. Value addition and special characteristics of AnGR - Particularities of local breeds

Date: Thursday 10 September 2026; 14:15 - 18:00
Chair(s): Berg, Schoon - Commission(s): G - Session Type: Theme session

Theatre Session 92

Maintaining agrobiodiversity: Holistic sensory and consumer testing of local chicken breeds and crossbreds thereof with commercial lines **1471**
D. Mörlein, C. Siebenmorgen, J. Mörlein, M. Strack, A. Risius

Assessment of post-thaw semen quality in two conserved Norwegian rooster lines **1472**
A. Kettunen, E. L. F. White, M. Honkatukia, N. Svartedal, A. K. Krogenæs, J. Peippo, A. Sayyari

Quo vadis Leicoma pig? **1473**
R. Schafberg, F. Rosner, B. Kröck, H. Reyer, M. Wensch-Dorendorf

Genomic relationships among four Northwestern European dual-purpose cattle breeds: Implications for strategic exchange and preservation of unique and shared genetic diversity. **1474**
J. Huisman, J. Hoorneman, J. Ten Napel, G. Brockmann , P. Korkuc , D. Todd , A. Blom, M. Schoon

Genomic analysis of genetic diversity and population stratification in Swabian-Hall pigs **1475**
L. Vollmer, J. Geibel, L. Kistner, A. Weigend, C. Worat, R. Weishaar, M. Petig, D. Hinrichs, S. Weigend, C. Reimer

Genetic Insights into the Diversity and Structure of European Draft Horse Breeds **1476**
L. Vostry, H. Vostra-Vydrova, A. Halvonik, N. Moravcikova, K. Palesova, R. Kasarda, B. Hofmanova, G. Mészáros, V. Cubric-Curik, I. Nagy, A. Bokor, I. Curik

Pedigree analysis and genomic characterization of two local German cattle breeds **1477**
V. Fenske, N. Krattenmacher, G. Thaller, D. Hinrichs

Historical expansion and severe recent demographic contraction in the South African Beef Shorthorn population **1478**
S. Lashmar, E. Cason

Genomic Structure of Local Sheep Breeds in Tunisia Using SNP Markers **1479**
I. Bensouf, I. Hayaha, N. Mhamdi, S. B. S. Gaouar

Genomic effective population size in two lines of mice divergently selected for homogeneity of birth weight **1480**
C. Ojeda-Marín, M. Saura, J. P. Gutiérrez, N. Formoso-Rafferty, I. Cervantes

Preliminary analysis of ancestral genomic effective population size in a SRC Iberian pig population selected for homogeneity of birth weight **1481**
C. Ojeda-Marín, M. Muñoz, F. Sánchez-Esquiliche, J. M. García-Casco, F. Goyache, J. P. Gutiérrez, N. Formoso-Rafferty, I. Cervantes

Poster Session 92

Preserving genetic diversity in the local Belgian Piétrain pig populations. **1482**
K. Wijnrocx, H. Wilmot, A. Markey, D. Duarte, P. Mayeres, N. Gengler

Leicoma Pigs – a Traditonal Breed Revived **1483**
L. Frenkel, B. Kröck, M. Wensch-Dorendorf, H. Reyer, F. Rosner, R. Schafberg

Session 93. Young Pig Management and Nutrition - Part 2

Date: Thursday 10 September 2026; 14:15 - 18:00
Chair(s): Lawlor, Trevisi, Girard - Commission(s): P - Session Type: Theme session

Theatre Session 93

From genes to practice: breeding for intestinal health and resilience **1484**
M. Fredholm

A dual-challenge model simulating subclinical post weaning enteric dysfunction in piglets: Impacts on gut integrity and markers of inflammation **1485**
D. Vodolazska, H. Nygaard Lærke, C. Lauridsen

Blood Transcriptomic Determinants of Post-Weaning Diarrhea in Commercial Pigs **1486**
M. Luigi-Sierra, J. Sun, E. Ibragimov, M. Kjelin Morsing, M. P. Rydal, J. P. Nielsen, P. Karlskov-Mortensen, S. Cirera, M. Fredholm

Digestibility and fibre degradation of wheat bran and Palmaria palmata in post-weaning piglets **1487**
C. Meyhoff Crone, K. E. Bach Knudsen, É. Chassé

Early-Life Robustness: Hematological and Immune Pathways Linking Pre-Weaning Growth to Post-Weaning Diarrhea Treatment **1488**
J. Sun, M. Luigi-Sierra, E. Ibragimov, M. Kjelin Morsing, M. Peter Rydal, J. P. Nielsen, P. Karlskov-Mortensen, M. Fredholm

Deciphering the intestinal pig microbiome and its function in early life **1489**
H. Smidt, M. Gujare, B. Ozdinc, J. Boekhorst, M. Kleerebezem

Species-level faecal microbiota development from suckling to 25 days postweaning in piglets: response to pre-weaning nutritional supplementation assessed by shotgun metagenomics **1490**
K. Jerez-Bogota, C. Lauridsen, D. Vodolazska, F. Asnicar, N. Canibe, O. Hojberg

Non Digestible Carbohydrate Structure Differentially Modulates Responses to ETEC F18 in Weaned Pigs **1491**
N. Razmgah, K. E. Bach Knudsen, M. Skou Hedemann, N. Canibe

Effects of Dietary L-glutamate, L-aspartate, and Their Combination on Growth Performance, Diarrhea Severity, and Amino Acid Digestibility of Weaned Piglets Challenged with Enterotoxigenic Escherichia coli **1492**
S. Wongchanla, Y. Park, S. Park, S. Sun, Y. Zhao, Y. Liu

Dietary protein and amino acid levels affect the gut metabolome and intestinal epithelial function in weaned piglets **1493**
L. H. Chen, M. S. Hedemann, S. Purup, K. Jerez-Bogotá, N. Canibe

Genetic Determinants of Gut Microbial Genera Abundance and Presence in Growing Pigs **1494**
E. Ibragimov, M. Luigi-Sierra, J. Sun, M. K. Morsing, M. P. Rydal, J. P. Nielsen, M. Fredholm, P. Karlskov-Mortensen

Session 94. Advancing Animal Welfare Assessment with PLF Technologies: Insights from the aWISH Project and related research - Part 2

Date: Thursday 10 September 2026; 14:15 - 18:00
Chair(s): Holinger, Maselyne, Blanco-Penedo, Van Noten - Commission(s): HW, SG, PLF, PO, P, G - Session Type: Theme session

Theatre Session 94

Stakeholder and consumer perspectives on animal welfare improvements in meat production **1495**
A. Kyriakidis, A. N. Louvrou, C. Hauschildt, M. Ntovas, I. Kostopoulos, E. Altsitsiadis, A. Stamos

Animal welfare and biosecurity on farm: are there conflicts? **1496**
C. Correia-Gomes, O. Soriano, L. M. Tamminen, G. Olmos Antillón, A. Burrell, E. Biebaut, T. B. Rodenburg, N. Van Noten, T. Tobias

Two frameworks for expert-based livestock welfare scoring: A comparative analysis **1497**
S. Verlinde, B. Forkman, F. Tuyttens, P. Llonch, B. Rodenburg, J. Verwaeren, J. Maselyne

Economic impact of enhanced pig welfare systems on Austrian finishing farms using information from automated monitoring **1498**
P. Thobe, M. Boimah, C. Pfeiffer

How to evaluate animal welfare improving initiatives on regional and national level? **1499**
M. F. Giersberg, N. Van Staaveren, K. Van Langeveld, N. Van Noten, F. A. M. Tuyttens, T. B. Rodenburg

From animal-based welfare indicators to EU policy integration: lessons from the aWISH project **1500**
H. Lambert

A systematic review of sensor technologies for automated welfare assessment of broilers **1501**
B. Forkman, P. Llonch, A. Ramon-Perez

Validation of an automated system for at-slaughter assessment of footpad dermatitis and hock burn in broiler chickens **1502**
N. Van Staaveren, K. Van Langeveld, J. Schulte-Landwehr, J. Mulder, P. Galliot, P. Créach, P. Sztandarski, J. Marchewka, B. Forkman, N. Van Noten, F. A. Tuyttens, M. F. Giersberg, T. B. Rodenburg

A molecular and biochemical reference approach for validation of vision systems that automatically record catching damage in broiler chickens at slaughter **1503**
P. Sztandarski, A. Jaszczyk, J. Marchewka, M. Solka, J. Rey-Gotxi, A. Szprynca, J. Schulte-Landwehr, J. Mulder, M. Kuras-Smolnik, F. Tuyttens, B. Rodenburg

Toward operational heat stress monitoring in poultry transport: a CFD-trained surrogate model **1504**
Y. Guyot, P. Créach

Impact of bird placement on Airflow Resistance in laying hen Transport Crates using a Porous Media Approach **1505**
N. Ulanowska, L. Rong, L. Van Dijk, A. B. Riber, L. Foldager, M. S. Herskin

Optimizing Pig Welfare Through Digital Transparency: A Multimodal Sensor System for Real-Time Transport Monitoring **1506**
M. Ganster, S. Herter, V. Restrepo, S. C. L. Fischer

"Best Practices" to improve broiler welfare – scientific experts' vs. poultry farmers' perspectives **1507**
M. Jachens, N. Kemper, M. Fels

Session 95. Innovations in equine feeding and management strategies

Date: Thursday 10 September 2026; 14:15 - 15:45
Chair(s): Julliand, Marchal - Commission(s): H - Session Type: Theme session

Theatre Session 95

Effect of season on pasture composition, intake, and health in horses **1508**
V. Milojevic, C. Omphalius, S. Julliand

The use of shade by grazing horses **1509**
J. Auclair-Ronzaud, C. Lesoudard, E. Montginoux, E. Legros, A. Leguerre, S. Henry

Investigation of a pivotal age in the ageing of digestive function in horses. **1510**
C. Omphalius, L. Marchal, G. Sorci, V. Milojevic, P. Grimm, S. Julliand

Chicory as an Antiparasitic Driver: Shaping the Parasite–Microbiota–Host Triad in the Equine Holobiont **1511**
N. Mach, S. Méndez, J. Malsa, J. Auclair-Ronzaud, D. Bars, M. A. Sevillia-Boisferon, G. Pot, H. Robert, M. Monié--Ibanes, A. Velarde, L. Lansade, A. R. Williams, E. Richard, G. Yannic, G. Bourgoin, G. Fleurance

The maternal vertical transmission of the bacterial microbiota shapes the foal microbiota on the long-term **1512**
L. Marchal, S. Julliand, G. Sorci, P. Grimm

Poster Session 95

Effect of alkaline reduced water on gastrointestinal inflammation in horses **1513**
S. Julliand, V. Milojevic, B. Von Rechenberg, A. Martin, P. Grimm

Horse feeding in relation to gastric health – nature does it best **1514**

Accurate methane phenotypes are essential for studying the genetic basis of methane emissions in dairy cows. However, methane concentration data collected with sniffers require considerable processing before they can be converted into reliable phenotypes. As a result, different data-processing pipelines are develop to handle the data. This leads to the question if these pipelines lead to meaningful differences in the resulting phenotypes and, consequently, in their genetic parameters estimated The objective of this study was therefore to estimate genetic parameters, including genetic correlations, for methane concentration using three different phenotype-processing pipelines, and to evaluate how the choice of pipeline influences the estimation of genetic variance components. The dataset consists of approximately 8,000 Dutch Holstein cows with about 90,000 weekly methane concentration records collected between 2018 to 2023 across 72 farms in the Netherlands using sniffer-based equipment. Several methane phenotypes were derived using three data-processing pipelines that differed in filtering criteria, alignment steps, and assumptions regarding visit length, background, etc. Each phenotype will be analyzed with a mixed model in ASReml to estimate heritability, genetic variance components, and genetic correlations among phenotypes. The results are expected to show that the choice of data-processing pipeline might affect the magnitude of genetic variance and, consequently, the estimated heritabilities. These findings will highlight the importance of harmonizing methane data-processing procedures in genetic evaluations and demonstrate how different phenotype constructions may affect the genetic parameters for methane emissions. This study is part of the Global Methane Genetics initiative, which is led by Wageningen University and Research and in partnership with the Bezos Earth Fund and the Global Methane Hub.

Genetic parameters for longitudinal CH_4 and CO_2 concentrations from sniffer sensors in automatic milking systems

J. M. Mbuthia[1], M. Stassen[1], S. König[1]
[1] Justus-Liebig-University, Gießen, Institute of Animal Breeding and Genetics, Ludwigstraße 21B, 35390 Gießen, Germany

Automated milking systems (AMS) combined with emission sensors enable continuous, high-frequency recording of cow performances and enteric CH_4 and CO_2 emissions under commercial farm conditions. The objective of this study was to use emission phenotypes from continuous AMS-sniffer measurements to estimate genetic parameters for CH_4 and CO_2 concentrations per AMS visit as well as for daily and weekly averages. Data were recorded in three commercial AMS farms in Germany between August and December 2025. Cow emissions were obtained from Moologer gas analysers (sniffer), installed in 12 Lely-Astronaut AMS. After merging the longitudinal AMS production and sniffer data, 122,007 records representing the informative AMS visits from 774 Holstein cows were available for the ongoing analyses. CH_4 and CO_2 concentrations (in ppm) per visit were further averaged per day and week yielding 58,111 and 14,923 records, respectively. Genetic parameters were estimated by applying repeatability (RM) and random regression models (RRM). For the RM, fixed effects included the parity and a regression on days in milk (DIM). Random effects included the combined herd-robot-test day effect to account for systematic differences between AMS/sniffer units and recording days, the additive genetic and the permanent environmental effects. The CH_4 repeatabilities were 0.32 ± 0.014, 0.47 ± 0.015 and 0.58 ± 0.015 for averages per visit, per day, and per week, respectively. Moderate repeatibilities were also estimated for CO_2 with 0.40 ± 0.015 (per visit), 0.50 ± 0.015 (per day) and 0.59 ± 0.015 (per week), indicating consistency of cumulative emission measurements with progressing time. Heritabilities for CH_4 from the RM were 0.24 ± 0.040 (per visit), 0.31± 0.049 (per day) and 0.30 ± 0.065 (per week), and heritabilites for CO2 0.22 ± 0.050 (per visit), 0.26 ± 0.052 (per day) and 0.27 ± 0.065 (per week). Aggregating emissions to daily and weekly measurements implied increased repeatabilities and heritabilities, due to the elimination of short-term "environmental noise" reflected through declining residual variances. The RMM considered the fixed effects from the RM and in addition, random regression coefficients for the additive-genetic and permanent environmental effects along DIM, modelled via Legendre polynomials of order 4. The quartic model presented moderate additive-genetic variation for CH_4 with h^2 ranging from 0.12 to 0.15 in the course of lactation. Genetic correlations between CH_4 from different time points were close to 1 for neighbouring DIM, and were lowest between early and mid-lactation with a minimal coefficient of -0.13 between CH_4 at days 1 to 5 and day 150. The genetic correlations from the multi-trait RM (simultaneously considering sniffer emission and AMS production traits) were 0.73, -0.04 and 0.05 between CH_4 with daily milk yield, protein content and fat content, respectively. Hence, selection for increased milk yield implies a proportional increase of methane concentrations. The genetic correlation between CH_4 and CO_2 was 0.98, indicating a shared genetic background for both emission traits. The dense sniffer data structure from AMS enabled RRM applications to study genetic effects for CH_4 and CO_2 concentrations along the time trajectory. The moderate and accurate heritability estimates indicate the potential of selection on reduced emissions, but it is imperative in ongoing studies to infer genetic covariances with further breeding goal traits during lactation.

Genetic parameter estimation for methane (CH4), carbon dioxide (CO2) and oxygen (O2) production in first parity Holstein cows

S. M. F. Cunha[1], F. S. Schenkel[1], F. Miglior[1,2], C. F. Baes[1]
[1] University of Guelph, Centre for Genetic Improvement of Livestock, 50 Stone Road East, N1G 2W1 Guelph, Canada, [2] Lactanet, 660 Speedvale Ave W, N1K 1E5 Guelph, Canada

Methane (CH4) and carbon dioxide (CO2) emitted by cows during eructation are key greenhouse gases (GHG) contributing to global warming. Methane has a short atmospheric lifetime, but its impact on climate change is acute, and actions to reduce its emissions will have a near-term effect. In contrast, CO2 has a longer atmospheric lifetime, and efforts to reduce its emissions are a long-term goal to decrease global temperatures. Systems like GreenFeed and sniffers that measure CH4 emissions also record CO2 production simultaneously. Despite the availability of CO2 records, research on genetic parameter estimates and their possible correlations with CH4 and other important economic traits remains limited. Thus, the objective of this study was to estimate genetic parameters for CH4 (g/day), CO2 (g/day), and O2 (g/day) production and to characterize the relationship among these traits. Records of CH4, CO2, and O2 production were measured in first-parity Holstein cows between 110 and 180 days in milk using a Greenfeed machine. Cows were sampled for 5 consecutive days (Monday to Friday), four times a day at 0800 h, 1200 h, 1600 h, and 2000 h (2017 to 2020) and 3 times per day at 0800 h, 1200 h, and 1600 h (2020 to 2025). The recording time length ranged from 2 to 20 minutes. After data cleaning, only cows with two or more records per day and at least one day of records were retained. Outliers were removed if values were 3 standard deviations above or below the mean. For each animal, records were averaged across the 5-day recording period to derive the final phenotype. Univariate and bivariate animal models were fit in ASREML. Only significant ($p < 0.05$) environmental fixed effects were included in the models. For CH4, the model included season of record (Srecord; four levels: 1 – from Jan to Mar; 2 – from April to June; 3 – from July to Sept; and 4 – from Oct to Dec) and year-season of calving (YScalving). For CO2, the effects of year-season of record (YSrecord) and YScalving were included in the model; for O2, the effects of year of record and YScalving were included. Heritabilities estimated were 0.44 (0.08), 0.36 (0.09), and 0.41 (0.08) for CH4, CO2, and O2 production, respectively. Genetic correlations were 0.70 (0.09) between CH4 and CO2 and 0.64 (0.10) between CH4 and O2. The CO2-O2 bivariate model did not converge. However, the correlation between the estimated breeding values from the univariate analyses was 0.90, suggesting a high underlying genetic correlation that may have hindered convergence. Phenotypic correlations were 0.68 (0.02) for CH_4–CO_2 and 0.61 (0.03) for CH_4–O_2. Residual correlations were 0.67 (0.05) for CH_4–CO_2 and 0.58 (0.06) for CH_4–O_2. The moderate heritabilities and strong genetic correlation between CH4 and CO2 indicate that selection to reduce one GHG gas is also likely to reduce the other. Because CH4 and CO2 can be measured concurrently with GreenFeed systems or sniffers on farms, these traits are promising candidates for inclusion in a multi-trait index designed to select animals that produce less GHG.

Genetic parameters of sniffer-based enteric methane concentration in dairy cows

N. Saedi[1], R. B. Stephansen[1], T. M. Villumsen[1], M. S. Lund[1], V. Milkevych[1], P. Løvendahl[1]
[1] Aarhus University, Center for Quantitative Genetics and Genomics, C. F. Møllers Allé 3, 8000 Aarhus, Denmark

Enteric methane (CH4) emissions from dairy cattle contribute substantially to greenhouse gas emissions, and genetic mitigation requires reliable phenotypes and robust parameter estimates for accurate breeding values. The objective of this study was to estimate variance components for sniffer-based CH_4 emissions in dairy cows and to evaluate the robustness of these estimates across different approaches of data-quality filtering. Records were collected from automatic milking systems (AMS) equipped with sniffers in Holstein Danish dairy herds, including up to 9,979 cows from 22 commercial farms. The raw data was processed using the Gas Emission Data Alignment (GEDA) pipeline, then the four study datasets were generated using variable data-quality filtering thresholds, where the threshold values are the local repeatability estimates calculated within processed sub-sets of data (no filtering, ≥30%, ≥35%, and ≥40%). As a result, the produced datasets differs by numbers of animals, farms, and recording units. Three methane phenotype definitions were evaluated: (1) the mean methane concentration per visit (ppm) (2) the daily mean methane concentration per cow, calculated by averaging all sensor observations recorded within a day (ppm), (3) Weekly methane phenotypes (ppm) were subsequently derived by correcting daily records for herd, AMS, sniffer, and day effects, then averaging the corrected values within weeks in milk (WIM). Repeatability models were fitted to daily, weekly, and per-visit methane phenotypes to enable direct comparison of genetic parameters across phenotype definitions. Linear mixed models included parity, herd × year × month × sniffer × AMS, and lactation stage effects (DIM and DIM² for daily and visits records, or WIM and WIM² for weekly records, together with the Wilmink function) as fixed effects, with additive genetic and permanent environmental effects modelled as random effects. Across all datasets, CH4 concentration exhibited low to moderate heritability, ranging from approximately 0.11–0.15 for per-visit phenotypes, 0.13–0.16 for daily phenotypes, and 0.22–0.23 for weekly phenotypes. As expected, repeatability increased, reaching the highest values for weekly methane phenotypes (0.57–0.62), compared with per-visit (0.27–0.39) and daily (0.32–0.41) phenotypes. Stricter data filtering reduced residual variance and increased thereby heritability and repeatability, while additive genetic variance estimates remained relatively stable across datasets. These results demonstrate that sniffer-based methane concentration traits are heritable, with heritability estimates increasing when stricter GEDA-based data-quality filtering criteria were applied. Repeatability was consistently higher than heritability, indicating a substantial contribution of permanent cow-specific effects. Overall, these findings support the feasibility of including sniffer-based methane phenotypes in breeding programs aimed at reducing the environmental footprint of dairy cattle.

Exploring the uniqueness of the genetic architecture of estimated methane emissions in Angler cattle based on existing prediction equations

K. Schröder[1], G. Thaller[1], L. Schwarz[1], M. Brandt[2], M. Gertz-Gerwinn[2], N. Gengler[3], Y. Chen[3], M. Albers[1], D. Hinrichs[4], N. Krattenmacher[1]

[1] University of Kiel, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany, [2] Landeskontrollverband Schleswig-Holstein, Steenbeker Weg 151, 24106 Kiel, Germany, [3] University of Liège, Gembloux Agro-Bio Tech, TERRA Teaching and Research Center, Passage des Déportés 2, 5030 Gembloux, Belgium, [4] University of Kassel, Faculty of Organic Agriculture, Section of Animal Breeding, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany

Methane emissions (CH4) vary among individuals and breeds and showed moderate heritability across studies making breeding strategies promising to achieve sustainable, cumulative and permanent reduction in CH4 in dairy cattle. Genome-wide association studies (GWAS) are gold standard to identify genomic regions associated with specific phenotypes such as CH4. Mid-infrared (MIR) spectra obtained from routinely collected milk samples in dairy cattle on a large scale can be used for the quantification of individual CH4. However, most research has been conducted in the Holstein Friesian (HF) breed, whereas there is a lack of studies for small local German breeds like Angler (RVA) concerning climate efficiency and the potential of breeding strategies to reduce CH4. Thus, this study aims to investigate the genetic background of estimated CH4 in RVA. Data from 2,451 cows (1,901 RVA; 550 HF) across lactations one to seven from sixteen farms in Northern Germany were available. Eight farms kept both breeds, enabling a comparison of the results between breeds. Given the limited number of HF animals in the sample, findings were additionally cross-checked against existing literature. Monthly milk samples from June 2023 to June 2025 were analysed and individual CH4 were calculated using two prediction equations based on MIR spectra respectively on fatty acids predicted from MIR spectra, resulting in slightly different mean values. The average CH4 (± SD) was 459.27 ± 69.59 g/d for RVA (467.94 ± 71.83 g/d for HF) calculated according to a modified version of the equation distributed by European Milk Recording and 404.69 ± 113.47 g/d for RVA (416.22 ± 125.14 g/d for HF) calculated according to the equation of the FBN Dummerstorf. Thus, the estimated average CH4 was slightly lower for RVA, regardless of the prediction equation applied. After filtering the genotype data for MAF < 0.01 and SNP call rate < 0.99 40,405 autosomal SNPs remained for RVA and 43,590 for HF, respectively. To identify the underlying genetic background, variance components were estimated using genomic restricted maximum likelihood (GREML) and GWAS were conducted using the tool GCTA with predicted CH4 for distinct lactation months (1-12) as phenotypes. Mixed linear models (MLMA) with fixed effects for lactation number and herd-year-month were used after prior testing of possible factors. In accordance with previous studies, heritability estimates ranged from 0.10 (± 0.04 SE) to 0.37 (± 0.06 SE) for RVA depending on the CH4 trait and lactation month and were mostly significant ($p < 0.001$). First GWAS results indicate promising genomic regions with significant SNPs as well as differences in the association patterns between traits and within traits across lactation. Further analyses are conducted to explore the genetic architecture and differences between breeds as well as potential interactions with different traits. Since the prediction equations do not yet specifically consider local breeds like RVA, methane measurement data is currently collected for RVA to validate or modify the equations for CH4 to improve subsequent analyses.

Phenotypic and genomic analyses of real and MIR-predicted methane phenotypes in Australian dairy cattle

S. Bolormaa[1], P. Ho[1], W. Hsieh[1], C. Vander Jagt[1], L. C. Marett[2], S. R. O. Williams[2], J. L. Jacobs[2], J. E. Pryce[1], R. Xiang[1]
[1] Agriculture Victoria, AgriBio 5 Ring Road, 3083 Bundoora, Australia, [2] Agriculture Victoria Research, 1301 Hazeldean Rd, 3821 Ellinbank, Australia

Methane emissions from dairy cattle are a major contributor to agricultural greenhouse gas (GHG) emissions. The current technologies (i.e., respiration chamber) are expensive and not scalable for phenotyping of methane. Milk mid-infrared (MIR) spectroscopy data is a high-throughput and cost-effective phenotyping tool and has emerged as a promising proxy phenotype for methane production. This study evaluated the potential of milk MIR spectra as a proxy for methane (Me) measurement in Australian dairy cattle and subsequently applied it in genomic prediction. We first benchmarked machine learning (ML) algorithms, including random forests, support vector machines, and artificial neural networks, with traditional partial least squares regression (PLSR) in phenotypic prediction of methane using milk MIR. The PLSR model then was applied to evaluate the phenotypic prediction of methane using directly measured methane and milk MIR phenotypes from 224 cows from Agriculture Victoria's Ellinbank SmartFarm (ELB) and 12,057 commercial (COMM) cows. We followed the routine protocol to pre-process MIR data and calibrated the prediction models to improve phenotypic prediction accuracy. The prediction model fitting the combination of 521 MIR spectra and parity or parity and milk yield was the best-performing models for methane production, achieving predictive accuracy up to r = 0.60. Heritabilities for MIR-predicted methane traits were estimated high with large standard errors due to a small size of training population (eg. $h^2 \approx 0.71$, s.e.= 0.17 using predicted phenotypes from model MIR and parity for ELB cows). Genetic correlations between real and predicted phenotypes reached 0.75 (s.e.=0.238) within ELB and 0.24 (s.e.=0.137) across COMM cows using bivariate regression analyses. Genomic prediction results using GBLUP showed that using MIR-predicted methane achieved a similar prediction accuracy to using directly measured methane. While the robustness of the Australian methane breeding value is yet to be improved, which requires a larger training population, MIR demonstrates promise for large-scale methane prediction and genomic evaluation for Australian dairy systems, offering a practical alternative to expensive direct measurement methods.

Rumen metabolites as potential indicators to mitigate methane emissions in dairy cattle

C. K. Anene[1], E. Karaman[1], G. Sahana[1]
[1] Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus, Denmark

Although multiple mitigation strategies have been proposed to reduce enteric methane (CH4) emissions from ruminant animals, methane production remains a major environmental challenge for the cattle sector. Genetic selection for reduced enteric CH_4 emission represents a promising and permanent mitigation strategy. However, accurate estimation of breeding values requires large-scale phenotyping, and direct CH_4 measurements are costly and typically limited to farms equipped with specialized infrastructure, such as automatic milking systems fitted with sniffer devices. Hence, cost-effective and biologically informative indicator traits are needed. Proxies related to rumen function, such as rumen microbial composition, fermentation pathways, and associated metabolites, offer mechanistic insight into methanogenesis at the molecular level and may capture host genetic variation underlying CH4 production. In particular, rumen metabolites involved in fermentation pathways could serve as practical indicator traits for mitigating CH4 emissions through selective breeding in dairy cattle. However, the extent to which host genetics regulates these pathways and their associated metabolites remains insufficiently characterized. This study evaluates the potential of rumen metabolites as indicators for enteric CH_4 emissions by estimating their heritabilities and their correlations with CH4 emissions. CH4 emissions were measured in approximately 500 Holstein dairy cows using the sniffer method, and CH4 concentration was used as the CH4 phenotype. Blood and rumen samples were collected and sent to the laboratory for NMR spectroscopy. The NMR spectra files from the lab were pre-processed in R using the AlpsNMR package, and metabolites in the rumen and serum samples were annotated using the ASICS package. Annotated metabolites were log-transformed before genetic analysis. Genetic variances and heritabilities of metabolites and CH4 phenotype were estimated using a single-trait animal model with parity as a fixed effect and Days in Milk as a covariate. Metabolites with heritability estimates greater than 0.05 were used to estimate genetic correlation with CH4 phenotype. Genetic and phenotypic correlations were estimated using a bivariate animal model with the same fixed effects and covariates as in the single trait model. 109 and 76 metabolites were annotated for serum and rumen, respectively. For serum, heritability estimates were very low (≤0.04) for 27 metabolites, low (0.05 to 0.19) for 61 metabolites, and moderate (0.20 to 0.38) for 21 metabolites. For rumen metabolites, heritability estimates were very low (≤0.04) for 43 metabolites, low (0.05 to 0.19) for 27 metabolites, and moderate (0.22 to 0.34) for 6 metabolites. In serum metabolites, Methylmalonic acid (MMA) recorded the highest heritability, while Malonate recorded the highest and lowest heritability in rumen metabolites. Of the 33 rumen metabolites used to estimate genetic correlation with the CH4 phenotype, 11 had negative genetic correlations (-0.36 ± 0.40 to -0.06 ± 0.51), and 22 had positive genetic correlations (0.03 ± 0.26 to 0.67 ± 0.54). The results of this study revealed that some rumen metabolites are heritable and are potential indicators for enteric CH_4 emissions. Furthermore, metabolites that were positively and negatively correlated with CH4 are known to be associated with hydrogen consumption and production pathways in the rumen. This study demonstrates the potential of rumen metabolites as indicator traits for enteric CH4 emissions in dairy cows, highlighting their suitability for large-scale phenotyping and their application in genetic selection programs aimed at mitigating methane emissions.

Genetic determinism of feed and water intakes and resilience traits in divergently selected RFI Romane sheep

C. Marie-Etancelin[1], K. Biard[1], J. L. Weisbecker[1], H. Lagarde[2], C. Coffre-Thomain[2], F. Tortereau[1]
[1] INRAE-GenPhySE, chemin de Borde rouge, 31326 Castanet-Tolosan, France, [2] INRAE-P3R, la sapinière, 18390 Osmoy, France

Improving feed efficiency is a key objective in animal production to reduce feed consumption and waste without compromising performance. Residual Feed Intake (RFI) is the most relevant criterion, as it identifies animals that eat less than expected for their production and maintenance needs. However, accurate RFI estimation requires individual feed intake measurements, which, in ruminants, depend on technically complex equipment, limiting large-scale phenotyping and selection. In contrast, individual water intake can be recorded using simpler devices, enabling the phenotyping of about four times more animals than forage intake systems. At INRAE P3R (https://doi.org/10.15454/1.5483259352597417E12), concentrate (ad libitum or restricted), forage, and water intakes for groups of 25 small ruminants can be recorded simultaneously during a single experiment. Since 2015, a divergent selection experiment on RFI under a 100% concentrate diet has been conducted in Romane meat sheep, based on young males' phenotypes. Between 2022 and 2025, around 640 sheep (350 males and 290 females) from the fourth to sixth generations were phenotyped. Males were recorded in spring for six weeks between 3 and 5 months of age under a 100% concentrate diet (Phase I) to establish the lines. The same males and their sisters were then recorded for six additional weeks between 6 and 8 months of age under a mixed diet with forage offered ad libitum and restricted concentrate (720 g for males, 660 g for females) in Phase II. Water intake was recorded during both Phase I and II. From daily intake (DI) records— of concentrate, forage, and water consumption—two resilience indicators were derived. First, the classical log-transformed coefficient of variation of daily intake, logCV(DI), was calculated. Second, the log-transformed variance of the area under the curve, logVar(AUC), was computed as a "consistency" criterion, as proposed by Cavani et al. (2023). Unlike logCV(DI), logVar(AUC) is independent of the total amount ingested and reflects the stability of daily intake fractionation patterns over time. The differences between the divergent RFI lines and the variance components were estimated for three traits: average daily intake (ADI), logCV(DI) and logVar(AUC), for the 4 ad libitum delivered feed (concentrate and water intakes during Phase I, and for forage and water intakes during Phase II). During early growth (Phase I), males consumed on average 2.28 ± 0.30 kg of concentrate and 6.68 ± 1.40 L of water per day. In Phase II (summer), water intake averaged 6.50 ± 1.45 L/day in males and 4.96 ± 0.96 L/day in females, while forage intake reached 1.24 ± 0.22 kg/day in males and 1.09 ± 0.19 kg/day in females. The line effect was highly significant for all intakes: in Phase I, RFI− males consumed 193 g less concentrate and 0.998 L less water per day than RFI+ males. In Phase II, efficient animals of both sexes consumed 110 g less forage and 0.764 L less water per day. Line effect was generally not significant for logCV(DI), except when calculated from water intake in Phase II, whereas a systematic difference was observed for logvarAUC, with higher values in efficient animals across all feed types. In males, ADI heritability ranged from 0.42 ± 0.10 (concentrate) to 0.68 ± 0.11 (water) in Phase I, and reached 0.59 ± 0.10 (forage) and 0.78 ± 0.11 (water) in Phase II. Resilience indicators showed null heritability for concentrate intake in Phase I, but reached 0.26 ± 0.10 and 0.22 ± 0.12 (consistency criterion) and 0.41 ± 0.11 and 0.44 ± 0.12 (logCV(DI)) in Phase II for forage and water intake, respectively.

Circadian feeding patterns in Swiss pigs are highly heritable and associated with feed efficiency

W. Gorssen[1], C. Winters[2], N. K. Kadri[1], N. Khayatzadeh[3], H. Pausch[1]
[1] ETH Zürich, Animal Genomics, Universitätsstrasse 2, 8092 Zürich, Switzerland, [2] ETH Zürich, Universitätsstrasse 2, 8092 Zürich, Switzerland, [3] SUISAG, Allmend 10, 6204 Sempach, Switzerland

Circadian eating patterns are the recurrence of eating behaviour along a 24-hour cycle and are thought to be controlled by the hypothalamus, stimulated by environmental factors such as light cycles. Pigs' feeding behaviour can be an important indicator of their performance, health and welfare but monitoring feeding patterns is challenging in livestock. However, the introduction of automated feeding stations now enables to study circadian eating patterns in depth. These data indicate that feed intake in pigs follows pronounced daily patterns, typically characterized by high intake in the morning and afternoon and minimal intake at nights. Here, we estimate the heritability of circadian feeding patterns and its relationship with feed efficiency in pigs. Feeding station data were obtained from the performance testing station of SUISAG, a Swiss breeding company, for pigs from the Swiss Landrace (SLR; n=2,575), the Swiss Large White dam line (SLWD; n=9,365) and Swiss Large White sire line (SLWS; n=2,687), covering the feeding period between 75 to 155 days of age. Pedigree data were available for all pigs and a subset of the phenotyped cohort had microarray-derived genotypes (SLR: n=1,625; SLWD: n=2,485; SLWS: n=360), which were imputed to the sequence-level. Feeding station records were aggregated to hourly feed intake, giving 24 observations per day and pig. Circadian patterns were quantified using wavelet analysis after de-trending and amplitude correction. For each pig and day, the strength of a circadian rhythm was assessed by comparing observed wavelet results with 200 white-noise simulations. Days with a mean p-value < 0.05 were classified as circadian, and the proportion of days with a circadian rhythm over the 80-day period reflects the strength of pigs' circadian eating patterns. Genetic parameters were estimated separately for each breed using single-step GBLUP implemented in gibbsf90+ software accounting for pen (random), sex and farm of origin (fixed) and the arrival weight and number of daily records (covariate). Genome-wide association studies (GWAS) were performed using GCTA-software, accounting for the same effects as described above and the first four principal components calculated from the genomic relationship matrix. The proportion of days with a circadian pattern showed substantial phenotypic variability, with a mean proportion of 0.46 (SD=0.30). Sex effects were highly significant ($p<0.0001$), with sows exhibiting the highest proportion of circadian days across all breeds followed by boars and barrows. The proportion of circadian days was negatively correlated with average daily feed intake ($r=-0.17$) and feed conversion ratio ($r=-0.21$), but not with daily gain ($r=0.01$), meaning that a stronger circadian feed intake improves feed efficiency. Heritability estimates for the proportion of circadian days were high across breeds (52.0-58.1%). A GWAS identified a QTL for the proportion of days with a circadian pattern on SSC4 for both SLR ($p=1.6\times10^{-8}$) and SLWD ($p=1.2\times10^{-12}$), near two functional candidate genes. Fine mapping is currently ongoing. Circadian eating behaviour showed substantial heritable variation and was favourably associated with feed efficiency, primarily through reduced feed intake without compromising growth. The identification of a shared, highly significant QTL on chromosome 4 in two independent breeds further supports a genetic basis for circadian feeding behaviour and highlights promising candidate regions for future functional analyses.

Plasma metabolomic signatures differentiate Duroc pigs with divergent feed intake: insights into the molecular architecture of a complex trait

S. Bovo[1], M. Bolner[1], C. Lewis[2], J. Holl[3], B. Valente[3], G. Schiavo[1], F. Bertolini[1], L. Fontanesi[1]
[1] University of Bologna, Dept. of Agricultural and Food Sciences, Viale G. Fanin, 40126 Bologna, Italy, [2] The Pig Improvement Company Europe, Sant Cugat del Valles, 08174 Barcelona, Spain, [3] The Pig Improvement Company, Genus plc, 100 Bluegrass Commons Blvd, Ste 2200, 37075 Hendersonville, United States

Feed intake is a biologically complex and economically relevant trait in pig production, influencing growth rate, efficiency, sustainability, and overall production costs. Its variability results from the interaction between environmental factors and genetically regulated biological processes operating across multiple molecular and physiological levels. Dissecting the molecular basis of feed intake is therefore essential to better understand its biology and to identify biomarkers that may improve breeding, nutritional strategies and the sustainability of pig production systems. Metabolomics, defined as the comprehensive analysis of low molecular weight molecules in biological systems, enables the exploration of intermediate molecular phenotypes linking genotypes to complex traits, potentially providing simpler and biologically informative proxies. The objective of this study was to identify plasma metabolites discriminating pigs with extreme and divergent feed intake and to evaluate their biological relevance. A total of 290 growing male Duroc pigs were selected from a larger performance-tested population and classified into high (n=150) and low (n=140) feed intake groups. Untargeted plasma metabolomics quantified 756 metabolites. After quality control, 587 metabolites spanning major biological classes were retained. Missing values were handled, generating 25 minimally different datasets. A robust feature selection pipeline based on the Boruta algorithm (Random Forest classifier) was applied across the 25 datasets, combined with 10-fold cross-validation, resulting in 1,250 feature selection runs. Metabolites consistently selected across runs were considered discriminant. Their discriminatory power was further evaluated using the ROC-AUC, principal component analysis (PCA), and standard Random Forest. Pearson correlations with raw feed intake were calculated, and biological interpretation was supported by pathway enrichment and metabolite network analyses. Twenty-nine metabolites (~5% of the filtered dataset) consistently discriminated between the two groups. Most were amino acids (66%), followed by nucleotides (17%), lipids (10%), one carbohydrate, and one unnamed compound. Amino acids were significantly over-represented (PFDR<0.05), whereas lipids were under-represented relative to the whole metabolome. Correlations with feed intake ranged from -0.40 to +0.34. AUC values ranged from 0.61 to 0.75, indicating moderate but consistent discriminatory capacity. PCA based on the 29 selected metabolites improved group separation compared with the whole-metabolome PCA. Pathway analyses highlighted enrichment of glutamate, histidine, branched-chain amino acids, and lysine metabolisms. These results support the hypothesis that specific plasma metabolites reflect biological mechanisms underlying feed intake variability. The predominance of amino acid signatures suggests an active involvement of protein and energy metabolism in differentiating intake extremes. In conclusion, the pig plasma metabolome contains reproducible molecular phenotypes associated with feed intake. These findings contribute to a better understanding of the biological architecture of feed efficiency and may support the development of metabolomics-informed breeding strategies. This study received funding from the European Union's Horizon Europe research and innovation program under grant agreement No. 101059609 (Re-Livestock project).

Functional impact of RNA-Seq derived SNPs associated with feed efficiency in Nellore cattle

M. Teodoro[1,2], G. Gubiani[3], A. Maiorano[4], L. Mota[2], A. Cánovas[1], F. Baldi[2,3]
[1] University of Guelph, Centre for Genetic Improvement of Livestock - Department of Animal Biosciences, 50 Stone Road East, N1G 2W1 Guelph, Canada, [2] São Paulo State University, Department of Animal Science, Via de Acesso Professor Paulo Donato Castellane, s/n, Zona Rural, 14884-900 Jaboticabal, Brazil, [3] University of São Paulo, Department of Veterinary Medicine, Avenida Duque de Caxias Norte, 225, 13635-900 Pirassununga, Brazil, [4] Federal University of Uberlândia, Department of Animal Science, BR-050 - KM 78, 38410-337 Uberlândia, Brazil

Feed efficiency (FE) is a polygenic trait of major economic importance that promotes resource optimization and economic viability in tropical beef cattle. Although genome- wide association studies have identified numerous quantitative trait loci associated with FE in Nellore cattle, the functional mechanisms driven by specific variants within these regions remain largely unclear. Moving beyond genomic location to transcriptomic function is crucial for refining genomic selection models. This study aimed to identify, functionally annotate, and analyze the metabolic pathways associated with single- nucleotide polymorphisms (SNPs) from RNA-Sequencing (RNA-Seq) data in Nellore cattle with contrasting residual feed intake (RFI) values. The RNA-Seq data from five tissues (liver, muscle, hypothalamus, pituitary gland, and adrenal gland) were analyzed for SNP detection in two groups, being 9 individuals with high RFI and 9 individuals with low RFI. Track tools were used to identify fixed and unique SNPs within each group. Amino acid changes (AAC) and splice effects (SE) were analyzed using CLC Genomics Workbench (Aarhus, Denmark). Functional impact of the identified variants was assessed using the Ensembl Variant Effect Predictor (VEP) based on the ARS- UCD1.3 assembly. Metabolic pathway enrichment analysis was performed using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database via the DAVID software. A total of 4,805 SNPs were identified, of which 2,525 were shared between groups, representing the common genetic background. In the low-RFI group, 1,029 SNPs were identified in overlap with 948 genes, comprising 144 AACs, 11 SEs, 3 variants with both AAC and SE, and 2 high-impact and 344 moderate-impact transcripts. Conversely, the high-RFI group exhibited a higher mutational load, with 1,251 SNPs in overlap with 1,016 genes, including 161 AACs, 14 SEs, and 6 AAC+SE. The high-RFI group presented more high-impact (8) and less moderate-impact (338) transcripts than the low-RFI group. A total of 61 pathways in the low-RFI group and 58 in the high-RFI group remained significant after false discovery rate correction (q < 0.05). Metabolic pathways, oxidative phosphorylation, and carbon metabolism were among the pathways across groups. The low-RFI group showed stronger enrichment in thermogenesis and fatty acid degradation, suggesting optimized energy expenditure. In contrast, the high- RFI group included pathways such as arginine and proline metabolism, indicating distinct nutrient partitioning potentially focused on metabolic maintenance. Interestingly, oxidative phosphorylation involved higher number of associated genes in the low-RFI group (44 vs. 35). This suggests a more robust mitochondrial capacity and fine-tuned energy metabolism in efficient animals, minimizing heat loss while maximizing nutrient utilization. Furthermore, the higher prevalence of high-impact functional variants in inefficient animals suggests a greater genetic burden affecting metabolic stability. These findings provide a functional map of genomic variations, highlighting specific targets to improve genomic prediction for FE in Bos indicus and advancing precision breeding programs for efficient animals.

Genetic correlation between deep phenotypes and measured phenotypes of feed efficiency

N. Adhikari[1,2], A. Van Der Linden[2], B. Gredler-Grandl[1], R. F. Veerkamp[1]
[1] Wageningen University and Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6700 AH Wageningen, Netherlands, [2] Wageningen University and Research, Animal Production Systems, De Elst 1, 6700 AH Wageningen, Netherlands

Deep phenotypes are the inner meta-mechanisms of feed efficiency. Using deep phenotypes, such as net energy efficiencies, in breeding may improve feed efficiency more rapidly than the current feed efficiency measures; gross feed efficiency, residual feed intake and feed saved. However, deep phenotypes are difficult and expensive to measure in practice. In earlier studies, deep phenotypes were therefore estimated by using LiGAPS-Dairy (a mechanistic model simulating feed efficiency), a genetic algorithm (optimization algorithm based on natural selection) and measured phenotypes. The measured phenotypes of feed efficiency were weekly fat- and protein-corrected milk yield (FPCM; kg/day), weekly dry matter intake (DMI; kg/day), and average weekly bodyweight (BW; kg), whose genetic correlations to the estimated deep phenotypes were not assessed in those studies. Hence, the present study aims to estimate the genetic correlation (rg) of deep phenotypes with FPCM, DMI, and BW. Eight deep phenotypes were estimated for 1,665 cows from 195,492 weekly FPCM, 56,511 weekly DMI, and 71,856 weekly BW records. The eight deep phenotypes were net energy for maintenance (NEm), intake capacity (Int_cap), maximum adult total body weight (TBW), the three parameters of Wood's lactation curve (W1, W2, W3), net energy efficiency for milk synthesis (NEEFF), and protein efficiency for milk synthesis (PROTEFF). A multivariate linear mixed model was fitted. Estimated rg between deep phenotypes and measured FPCM, DMI, and BW ranged from strongly positive (0.96 ± 0.01) to strongly negative (-0.75 ± 0.10). Similarly, strong positive rg between W2 and FPCM (0.94 ± 0.03), Int_cap and FPCM (0.77 ± 0.06), TBW and DMI (0.79 ± 0.02), TBW and BW (0.96 ± 0.01), and W2 and DMI (0.88 ± 0.03) were found. Negative rg were found between W3 and FPCM (-0.66 ± 0.10), W3 and DMI (-0.75 ± 0.10), PROTEFF and DMI (-0.67 ± 0.04), PROTEFF and BW (-0.31 ± 0.04), and NEEFF and DMI (-0.37 ± 0.06). Overall, selection on deep phenotypes for feed efficiency is expected to produce correlated responses in production traits. Next step is to estimate rg between deep phenotypes and gross feed efficiency, residual feed intake and feed saved. Key words: Deep phenotypes, mechanistic model, genetic correlation, feed efficiency

Genetic analyses of the relationships among milk yield, feed intake, body weight and energy balance in Holstein Friesians using selected SNP subsets

C. Piefke[1,2], C. Schmidtmann[2], H. Alkhoder[2], H. Schneider[3], J. Tetens[4], J. Bennewitz[5], G. Thaller[1]
[1] Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [2] IT-Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany, [3] SEGES Innovation P/S, Agro Food Park 15, 8200 Aarhus N, Denmark, [4] Georg-August-University, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, [5] University of Hohenheim, Institute of Animal Science, Garbenstrasse 17, 70599 Stuttgart, Germany

In modern dairy cattle breeding, the focus has expanded beyond productivity and increasingly encompasses animal health and robustness. In early lactation, dairy cows frequently experience a negative energy balance, where energy needs for milk production and maintenance exceed the energy intake, compromising immune competence, and increasing the incidence of diseases. Previous research has confirmed genetic links among milk yield (MY), dry matter intake (DMI), and energy balance (EB) in dairy cows. Building on these findings, the present study explores these relationships in greater depth, with the goal of revealing underlying biological mechanisms and molecular genetic insights. Using selected SNP subsets, genomic heritabilities and correlations were estimated across lactation for MY, DMI, EB and body weight (BW), to determine the contribution of these subsets to the genetic architecture of the traits. Weekly records for MY, DMI, EB and BW from 3,485 lactations of 2,188 Holstein Friesian cows were available, along with imputed whole-genome sequence data (WGS) containing ~ 17 million SNPs for all animals. WGS data was partitioned into subsets and three subsets were selected for this study: Selection Signatures (SelS, 1,787 SNPs), metabolic QTL (mQTL, 5,102 SNPs) and SNPs used for routine genetic evaluation (50k, 44,315 SNPs). Traits were analyzed with single-trait random regression models, while genomic correlations were estimated with pairwise bivariate random regression models. Heritabilities ranged from low to moderate, with 0.027 (±0.010) for EB to 0.194 (±0.019) for MKG. While heritabilities estimated with the subset 50k were highest, subsets mQTL and SelS explained a considerable proportion of heritability despite their much smaller SNP counts. This indicates a potentially functional and biological significance of these genomic regions for the traits under study. The subset SelS contains functional SNPs that occur significantly more frequently in dairy cattle, thereby capturing relevant genetic variation for the investigated traits. The subset mQTL includes SNPs associated with milk fatty acid concentrations and is predominantly located in functional genomic regions marked by methylation. Since these variants are closely linked to metabolic processes and milk fat synthesis, particularly during phases of negative energy balance, they capture genetic effects directly related to MY, DMI, and EB. Genomic correlations ranged from −0.285 (±0.109) between MY and EB to 0.596 (±0.073) between MY and DMI, with the strongest estimates found when using the 50k subset. However, for the other two subsets, correlations were only slightly lower, highlighting the substantial relevance of the genomic regions they contain for MY, DMI, BW and EB. Overall, the results support the hypothesis that the analyzed subsets of SelS and mQTL harbor causal mutations that substantially contribute to the genetic variation of the investigated traits. In a next step, a direct health trait (e.g. mastitis) will be incorporated into the analyses in order to investigate its relationship with the traits already examined, which could provide valuable insights for improving animal health and breeding strategies.

Genetic parameters of residual carbon dioxide as a feed efficiency indicator in Fleckvieh cows

S. J. Burn[1], B. Fuerst-Waltl[1], A. Köck[2], K. Linke[2], C. Schmid[3], C. Egger-Danner[2], W. Zollitsch[1]
[1] BOKU University, Department of Agricultural Sciences, Gregor-Mendel-Straße 33, 1180 Vienna, Austria, [2] ZuchtData EDV-Dienstleistungen GmbH, Dresdner Straße 89, 1200 Vienna, Austria, [3] LKV Austria Gemeinnützige GmbH, Dresdner Straße 89, 1200 Vienna, Austria

Enhancing feed efficiency is a key goal in livestock breeding for economic and environmental reasons. However, routine recording of feed intake, which is required to derive feed efficiency traits, is unavailable for Fleckvieh (dual-purpose Simmental) cows. Residual carbon dioxide (RCO2) may be a suitable proxy, since CO2 production reflects metabolic heat production, which is linked to feed intake and metabolic rate. The objectives of this study were therefore to (1) characterize phenotypic patterns of RCO2 across commercial farms, and (2) estimate the heritability and genetic correlations of RCO2 and related traits. The dataset comprises CO2 data collected from 14 Austrian commercial farms using a GreenFeed system for a period of at least six weeks, alongside with daily milk yield (MY), weekly milk samples, and daily body weight (BW). It included 722 Fleckvieh cows, with 62,756 GreenFeed records, 26,688 MY records, and 30,759 BW records, aggregated to 1,836 weekly averages from 427 cows with complete data. The five-generation pedigree included 20,056 animals. RCO2 was defined as the residual from a linear model regressing weekly CO2 on energy-corrected milk (ECM), metabolic BW, and BW change, including test week as a random effect. The differences between farms for CO2 and RCO2 were first descriptively analyzed and then tested using Welch's ANOVA, followed by Games-Howell post-hoc comparisons. For the genetic analyses, a multiple-trait repeatability animal model was used to estimate the genetic parameters of ECM, BW, CO2, and RCO2. The model accounted for the fixed effects of herd, parity, and days in milk, as well as the random effects of herd-trial-test-week, permanent environment, and additive genetic effects of the animal. The mean values of CO2 and RCO2 differed significantly between farms, ranging from 12,228 to 15,476 g/day and -1,360 to 561 g/day, respectively. Additionally, substantial variation was observed within farms. The heritabilities of CO2 and RCO2 were low to moderate, and the two traits were strongly genetically correlated. As expected, CO2 showed stronger genetic correlations with ECM and BW than RCO2. In conclusion, these findings provide initial insights into RCO2 derived from on-farm data and its genetic properties for Fleckvieh cattle. Validation against station data with measured feed intake is a critical next step.

The impact of selection for methane emissions in dairy cattle on herds with different sizes

C. Labauge[1], E. Tourrette[1], M. Eugène[2], L. Barreto-Mendes[3], B. Cd Cuyabano[1]
[1] Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350 Jouy-en-Josas, France, [2] INRAE, ASSET, Centre Antilles-Guyane, Domaine Duclos, Prise d'Eau, 97170 Petit Bourg, Guadeloupe, France, [3] Université Clermont-Auvergne, INRAE, VetAgro Sup, UMR Herbivores, F-63122 Saint-Genès-Champanelle, France

Livestock farming contributes 16% of methane emissions worldwide (Vettoretti, 2024). Moreover, it has been shown that production traits and methane, a greenhouse gas, emissions were positively correlated in dairy cattle ($\rho = 0.2$). Thus, including new traits, such as methane emissions, in selection for dairy cattle is a solution to control the impact of livestock production on global warming and climate change (Bačėninaitė et al. 2022). The ISU (Unified Selection Index) defines the selection objectives of a breed. In particular, the ISU indicates the traits under selection and their selection intensity, determined by their economic value, heritability and genetic correlations with other traits. For example, in the Holstein dairy breed, the 2024's French ISU is mostly defined by milk production, fertility, morphology and health. No environmental considerations are included. (Prim'Holstein France 2024) Although some countries, such as Denmark, are already including methane emissions into their selection program (Hafsa 2024; VikingGenetics 2025), one of the main obstacles to adding methane emissions into the dairy cattle's ISU is the lack of objective economic values attributed to them. Moreover, milk production and methane emissions are positively correlated, leading to a potential decrease of the production if methane emissions are selected against. The imminent demand of an ISU including methane emission drives the need to understand the impact of such new indexes, not only at a population level but also on each farmers' context. Particularly, depending on the herd size of each farm, the economic impact of including methane emission in the ISU will vary and will depend on total milk production relative to maintenance costs. For example, a loss of 10% milk yield for a farm with 10 cows will have a much greater economic impact than for one with 150 animals, where maintenance costs per kg of milk tend to be lower.By simulating a dairy cattle breeding program with four traits representing production, fertility, health and methane emissions, we aimed to study the impact of adding methane emission in the selection index on the genetic progress of all traits, and determine the optimal selection strategy based on the herd size. Traits were simulated with genetic parameters similar to those of a French Holstein population, in particular with a genetic correlation between production and methane emission equal to 0.2. Different weights for the four traits were tested, from the current ISU with no weight on methane emission, to strong selection against it. Cows were separated into 200 farms of different sizes (5, 15, 35, 75 or 145 cows) with a common bull nucleus for selection. We evolved the populations over 10 generations, comparing the genetic progress and the trends in genetic variances and correlations for the different herd sizes. Preliminary results have been obtained, showing coherence with the initial chosen parameters. We observed an increase of the methane emissions in the cases of the ISU without methane emissions, similar for all farms. On the contrary, genetic variances of small farms compared to large ones were lower, but with higher standard errors. These results thus show that herd size plays a role on the consequences of selection, and should be considered when defining breeding goals. This study was carried out as part of the project OPTI-HERD, which simulates farming systems, taking into account adaptation and mitigation of climate change.

Genetic mitigation of methane emissions in Nordic Red dairy cattle through international data integration and joint genomic evaluation

Enteric methane (CH_4) emissions from dairy cattle represent a significant source of greenhouse gases. Genetic selection can serve as a mitigation strategy, provided there are extensive, well-connected reference populations and standardized phenotypes across different recording methods. While methane breeding values have been developed for several Holstein populations, their adoption within Red Dairy Cattle (RDC) breeds remains limited. The purpose of this project is to promote international phenotyping and harmonized data integration, enabling reliable genomic predictions of methane emissions, and supporting their implementation in breeding programs for RDC populations. The Red Dairy Project, part of the Global Methane Genetics initiative, aims to accelerate methane phenotyping in RDC while integrating data from multiple countries and recording systems. Methane measurements are collected using sniffers and GreenFeed units, with overlapping data sets obtained from selected herds. Fourteen sniffers are being installed across Denmark, Finland, Norway, and Sweden following standardized protocols and harmonized editing pipelines. Traits under consideration include methane production, concentration, intensity, and residual methane. Single-step genomic BLUP models will be used for genetic analyses, and data from Canada and the United Kingdom will be included to evaluate the effect of expanding the reference population and to quantify genetic connectedness. This project lays the groundwork for joint genomic studies of methane emissions in RDC breeds. By creating the largest standardized methane dataset encompassing diverse countries and recording systems, this initiative facilitates effective low-methane breeding programs within RDC and promotes international data sharing to expand global impact.

Mitigation strategies for methane emission in dairy cattle production

K. Msibi[1]
[1] *Goerg-August-Universtät-Göttingen, Agrarwissenschaften, Albrecht-Thae-Weg-3, 37075 Göttingen, Germany*

Enteric methane (CH_4) in dairy cattle is produced during anaerobic rumen fermentation by methanogenic archaea and represents a major source of greenhouse gas emissions as well as a loss of dietary energy that reduces feed efficiency. Therefore, methane mitigation is an important target for improving both productivity and environmental sustainability in dairy systems. This review assessed methane mitigation strategies in dairy cattle, focusing on nutritional modification, microbiome-based interventions, and genetic selection. Nutritional modification showed the most immediate mitigation potential. Supplementation with 3-nitrooxypropanol (3-NOP) produced the strongest and most consistent reductions, lowering methane production by 32.7%, methane yield by 30.9%, and methane intensity by 32.6% at a mean inclusion rate of 70 mg/kg diet dry matter. These reductions, equivalent to nearly one-third of emissions, indicate substantial improvements in feed energy utilization and a meaningful decrease in the environmental footprint of milk production. Dietary nitrate supplementation achieved moderate reductions, decreasing methane production by at least 20.3%, methane yield by 16.4%, and methane intensity by 20.1%, although responses varied with diet composition. Tannin-based additives reduced emissions by approximately 10%, suggesting a supportive role, while essential oil blends resulted in smaller but measurable reductions (8.8% in methane production, 12.9% in methane yield, and 9.9% in methane intensity) during long-term supplementation. Microbiome-based interventions demonstrated that methane mitigation is closely linked to shifts in rumen microbial structure and function. The effect of 3-NOP was associated with reduced abundance and transcriptional activity of Methanobrevibacter spp., including downregulation of the mcrA gene central to methanogenesis. Rumen defaunation led to short-term reductions of 20–50%, highlighting the importance of protozoa–methanogen interactions, although these effects were often transient. Rumen microbiota transplantation produced smaller reductions of 5–15%, with microbial communities frequently reverting toward their original state, indicating limited long-term stability. Genetic association studies reported moderate heritability estimates (0.18–0.24) for methane production, yield, and intensity, indicating that 18–24% of variation in these traits is attributable to additive genetic effects and confirming the potential for sustained genetic progress through selection. While nutritional and microbiome-based strategies are effective during active application, genetic selection offers cumulative and permanent reductions across generations. Overall, feed-based interventions can deliver rapid reductions of up to one-third of emissions, whereas genetic selection provides a long-term, scalable strategy for sustainable methane mitigation in dairy production systems. Keywords: enteric methane; dairy cattle; genetic selection; rumen microbiome; sustainable livestock production

First measurements of methane emissions in the Manech Tête Rousse dairy sheep breed

F. Tortereau[1], N. Lesueur[1], G. Affraix[2], J. M. Astruc[3], C. Marie-Etancelin[1]
[1] UMR GenPhySE, INRAE, Université de Toulouse, ENVT, Chemin de Borde Rouge BP 52627, 31326 Castanet-Tolosan, France, [2] CDEO, 140 route Ahetzia, 64130 Ordiarp, France, [3] idele, Chemin de Borde Rouge BP 52627, 31326 Castanet-Tolosan, France

Livestock productions are facing several environmental, societal and economical challenges. Major environmental challenges relate to climate change, such as feed-food competition, use of arable lands and the environmental footprint. Ruminants, thanks to their ability to transform fibers into edible food can marginally contribute to the feed-food competition, but the unfavourable counterpart of the ruminal fibres' fermentation is methane emissions. Several levers are investigated to tackle methane emissions from ruminants, genetic selection being one of them. Phenotyping is the first step when it comes to implement a new trait in a breeding program. In sheep, Portable Accumulation Chambers (PAC) have been developed to enable phenotyping of methane emissions on large numbers of animals, directly in their production areas and systems. PAC have been mainly used in meat sheep for which genetic parameters have already been published for different breeds. In dairy sheep, the literature is scarce both for PAC phenotyping and for estimates of genetic parameters of methane emissions. INRAE is equipped with PAC and first measurements on dairy sheep were performed on Manech Tete Rousse (MTR) rams bred at the CDEO animal insemination centre. A total of 243 MTR rams were phenotyped in 2025. Young rams genomically preselected (1 year old) were phenotyped in December whereas older rams (with daughters) were phenotyped in November. All these rams have genomic estimated breeding values (GEBVs) for milk traits (milk, protein and fat yields, fat and protein contents), somatic cells and udder morphology, as well as a production index combining yield and content (milk_index) and a total merit index combining all the above selected traits (TMI). PAC measurements consist in 3 gas traits (CH4, CO2 and O2) in g/d, from which 2 additional traits are calculated: (CH4+CO2) considered as a proxy of feed intake and methane yield calculated as CH4 divided by this proxy (ie (CH4+CO2)). All rams had body weight recorded during the week of the PAC measurements. The objective of this work was to describe gas traits and to estimate correlations between these traits and selection indices. On average, rams emitted 22.97 ± 6.98 g CH4/d, 1943 ± 839 g CO2/d and consumed 1174 ± 355 g O2/d. Old rams emitted more methane than young rams (21.29 g/d and 25.35 g/d, respectively), in line with the significant difference in body weights (49.47 kg and 67.71 kg, respectively). Similarly, older rams emitted more CO2 and consumed more O2 than young rams. However, methane yield was not significantly different between old and young rams. These phenotypic values are consistent with those in the literature, although most studies have been conducted on meat sheep breeds. No significant correlation was estimated between methane traits and GEBVs. Body weight was significantly correlated with selection indices (milk_index and TMI), but this was due to the known bias with genomic evaluations where young animals (which are also lighter than older animals) are overestimated. This significant correlation disappeared when the age of the animals was considered. Similarly, some correlations between CO2 and O2 were significantly negative with selection indices, but turned to be equal to zero when the age of the animals was considered.

Development of QuickFlux for measuring enteric methane and carbon dioxide fluxes from dairy cattle and their association with dry matter intake

L. Cavani[1], A. Lago[2], G. Martinez-Boggio[3], E. Kebreab[3], F. Peñagaricano[4], S. Zimmerman[1]
[1] C-Lock Inc., 1350 Concourse Dr., 57703 Rapid City, United States, [2] DairyExperts Inc., 17721 Rd 112, 93274 Tulare, United States, [3] University of California - Davis, Department of Animal Science, One Shields Avenue, 95616 Davis, United States, [4] University of Wisconsin - Madison, Department of Animal and Dairy Sciences, 1675 Observatory Drive, 53706 Madison, United States

In dairy production systems, enteric methane (CH4) is a major contributor of greenhouse gas emissions. In addition to its environmental impact, enteric CH4 represents a loss of gross energy that could otherwise be directed toward production. Moreover, CH4 and carbon dioxide (CO2) have been explored as predictors of intake and feed efficiency. The objective of this study was to evaluate the association between gas fluxes, measured using a novel technology (QuickFlux, C-Lock Inc.), and dry mater intake (DMI) in dairy cows. QuickFlux was developed to quickly and quantitatively measure mass flux rates of metabolic gases from the muzzle of cattle, it includes a gas-capturing assembly consisting of a collector, airflow pipe, air filter, fan that pulls air through the system at 40 L/s, and individual gas sensors. Gas mass flux rate is calculated by multiplying the airflow rate by the increase or decrease in concentration of each gas from its background and ideal gas laws are used to convert gas volume to gas mass in g/d. Data were collected from 76 multiparous lactating Holstein cows at California's Central Valley (DairyExperts Inc., Tulare, CA). QuickFlux sampling was conducted while animals were in the milking parlor. Each cow was sampled 9 times: 7 samples were collected once weekly during the morning milking (0700-1000 h), and in the final 2 weeks, samples were also collected during the afternoon milking (1800-2000 h) on the same day. Cows were fed a common diet and housed in a free-stall barn with access to GreenFeed. QuickFlux measurements (CH4 and CO2; g/d) were collected individually and the duration of each measurement was 5 min. Daily milk yield (MY) and DMI, lactation number, and days in milk (DIM) were recorded. Partial regression coefficients and coefficients of determination (adjusted R^2) for DMI were compared between QuickFlux and GreenFeed using six multiple linear regression models. All models included DIM and lactation (Lac), both with 3 levels. Model 1 included DIM, Lac, MY, CH4, and CO2; Model 2 included DIM, Lac, MY, and CH4; Model 3 included DIM, Lac, MY, and CO2; Model 4 included DIM, Lac, CH4, and CO2; Model 5 included DIM, Lac, and CH4; and Model 6 included DIM, Lac, and CO2. Variables were averaged per cow. Adjusted R_2 values were similar between QuickFlux and GreenFeed for all models: 0.68 and 0.66 for Model 1; 0.62 and 0.59 for Model 2; 0.66 and 0.67 for Model 3; 0.54 and 0.49 Model for 4; 0.44 and 0.36 for Model 5; 0.49 and 0.48 for Model 6. Partial regression coefficients did not differ between QuickFlux and GreenFeed. CO2 slopes were significant ($P < 0.01$) for all models and were approximately 0.001 g/d. CH4 slopes were not significant in models that included CO2 (Models 1 and 4); in Models 2 and 5, the slopes were 0.02 and 0.03 g/d, respectively. Our results showed that predicting DMI using CH4 and CO2 fluxes may lead to similar results whether they are measured with QuickFlux or GreenFeed, suggesting that QuickFlux is a feasible technology for measuring gas fluxes in dairy cows, with strong potential for predicting DMI and feed efficiency. Keywords: GreenFeed, feed efficiency, phenotyping

Genetic and epigenetic hotspots in the Nelore cattle genome associated with residual methane emission

Methane emissions from cattle are a major contributor to greenhouse gas emissions. Understanding its biological regulation is essential for sustainable livestock systems. Herein, we identified genetic and epigenetic regulatory hotspots associated with residual methane emission (RME) in Nelore cattle by integrating genetic and epigenetic data from rumen tissue. We selected contrasting sample groups for low (LRME, N=4) and high (HRME, N=4) residual methane emission for ChIP-Seq and ATAC-Seq assays from a population of 26 animals with available RNA-Seq and residual methane emission data. Differential expression analysis identified 21 differentially expressed genes (DEGs), e.g., ADIPOQ, LIPE, PLIN1, CIDEC, THRSP, and TRARG1 associated with lipid metabolism and others linked to immune response and intracellular signaling pathways. Epigenomic analyses revealed eight differentially bound regions (DBRs) for H3K4me1, 506 for H3K4me3, 10 for H3K37ac and 12 for CTCF, and 11 differentially accessible regions (DARs). Footprinting analysis of ATAC-Seq data identified 83 transcription factors (TFs) with differential binding patterns between groups, resulting in thousands of specific TF binding sites (TFBS) per group. Integration of epigenomic and genetic variation data identified eight DEGs with TFBS unique to one group, including SMOC1 and MYOC, which also harbor SNPs with significantly different allele frequencies between LRME and HRME. Additionally, 13 regions of 13 different genes showed overlapping DBRs across two histone modifications, some of which also contained group-specific TFBS. These integrated signals defined 21 candidate hotspots, being eight genes and 13 epigenomic regions, associated with residual methane emission. Functional annotation suggests that these hotspots are involved in energy metabolism, immune modulation, and cellular signaling processes in the rumen tissue. Our results provide a view of the regulatory mechanisms underlying methane emission in cattle, with coordinated genetic and epigenetic control in the rumen. The identified hotspots are candidate targets for future studies and potential biomarkers for genetic and epigenetic selection aimed at reducing methane emissions in cattle. Keywords: RNA-Seq, histone modification, methane.

Estimation of genetic parameters of resilience indicators from feeding behavior in the Iberian pig

F. Barceló-Blasco[1], P. Núñez[1], N. Ibáñez Escriche[1], J. Casellas[3], M. Sánchez-Díaz[2], S. Negro[4], L. Varona[2]
[1] Universitat Politècnica de València, Valencia, 46022 Valencia, Spain, [2] Universidad de Zaragoza, Zaragoza, 50009 Zaragoza, Spain, [3] Universitat Autònoma de Barcelona, Bellaterra, 08193 Barcelona, Spain, [4] IngaFood S.A., Almendralejo, 06200 Badajoz, Spain

Animal resilience refers to the capacity of an animal to maintain stable performance under environmental or health-related challenges and to recover rapidly to its original or optimal state. Despite its growing relevance in breeding programs, there is still no consensus on the most appropriate indicator to quantify resilience. The objective of this study was to evaluate the genetic potential of three resilience indicators derived from feeding behavior: (a) the natural logarithm of the mean squared error (lnMSE), (b) skewness (Skew), and (c) first-order autocorrelation (Lag1). For each animal, a simple linear regression of the trait was fitted. The residuals, representing deviations from expected performance, were used to compute lnMSE, Skew, and Lag1. These indicators capture complementary dimensions of resilience: lnMSE reflects the overall magnitude of deviations, Skew identifies asymmetric perturbations, and Lag1 quantifies the temporal persistence of deviations. Indicators were computed from records of daily feed intake (DFI), time per visit to the feeder (TPV), and number of visits per day (NVD) from 1,573 purebred Iberian males monitored between 80 and 180 days of age at a commercial testing station in Spain (2020–2025). The pedigree included 2,899 animals. Variance components, heritabilities, and genetic correlations were estimated using bivariate animal models through Bayesian analysis with a Gibbs sampler. Heritability estimates for lnMSE were 0.305, 0.334, and 0.233 for DFI, TPV, and NVD, respectively, and were higher than those obtained for Skew and Lag1. For Skew, heritabilities were 0.167, 0.082, and 0.161, while for Lag1 they were 0.175, 0.095, and 0.147. Genetic correlations showed heterogeneous and in some cases antagonistic patterns: Lag1 indicators generally showed positive correlations with each other, lnMSE exhibited more neutral to slightly negative correlations, while Skew displayed the most divergent correlations (0.538 to −0.836). Some were clearly positive (>0.70), such as lnMSE for TPV and Skew for NVD (0.912) or Skew for TPV and lnMSE for NVD (0.798). In contrast, others were strongly negative, such as Skew and lnMSE for TPV (-0.871) or Skew for DFI and Lag1 for TPV (−0.820). Given the low heritabilities and moderate sample size, these correlations should be interpreted with caution. Overall, the results indicate that these indicators exhibit heritabilities high enough to support breeding strategies aimed at improving resilience. However, the variability in genetic correlations suggests that each indicator captures distinct aspects, highlighting the need to refine or combine metrics for a more comprehensive characterization of resilience. The antagonistic relationships between some trait pairs may represent genuine opposing genetic mechanisms but could also be influenced by statistical uncertainty due to low heritabilities, underscoring the need for larger datasets and further validation before drawing definitive conclusions about the genetic architecture of resilience traits or making recommendations for indicator selection in breeding programs.

Absence of trade-offs between productive traits and immune competence in Dohne Merino

T. Freire[1], G. Ciappesoni[2], I. De Barbieri[2]
[1] Universidad de la República, Facultad de Medicina, Avenida General Flores 2125, 11800 Montevideo, Uruguay, [2] Instituto Nacional de Investigación Agropecuaria, Sistema Ganadero, Ruta 5. km 386, 45000 Tacuarembó, Uruguay

A potential antagonism between productive and efficiency traits and the ability of livestock to develop an adequate immune response has been proposed in ruminant production systems. Therefore, the aim of this study was to evaluate productive performance and feed efficiency in Dohne Merino ewe-lambs with contrasting immune competence measured at weaning. The performance of forty-four Dohne Merino ewe-lambs (2024 cohort) was evaluated during their first 10 months of life. Animals were spring-born (August-September), and their ability to mount cell-mediated (Cell-IR) and humoral (Ab-IR) immune responses was assessed at weaning. Ewe-lambs were vaccinated subcutaneously at marking (7-weeks of age) and weaning (14-weeks of age) with 1.0 mL of a clostridial vaccine (Clostrimax T®). On day 12 post-weaning, two intradermal injections (100 µL each) were administered in the inguinal region: vaccine antigen and a sterile saline control (0.9% NaCl), using a 30G needle. Skinfold thickness at each injection site was measured in triplicate immediately before injection and again 48 h later (day 14). The magnitude of the cell-mediated immune response was calculated as the log ratio of post-injection skin thickness at the vaccine site relative to the control site, adjusting for baseline measurements. Humoral immunity was assessed by measuring serum anti-tetanus toxoid IgG1 concentration in blood samples collected on day 14 post-weaning. Antigen-specific IgG1 was quantified by indirect ELISA, with samples and controls analysed in quadruplicate and quality-controlled using coefficient of variation thresholds. Residual feed intake, feed intake, methane emissions, animal growth, rib eye area and backfat thickness were evaluated immediately after immune competence assessment during a 56-day feed efficiency test. Subsequently, resistance to gastrointestinal nematode infestation was assessed in autumn. First shearing was performed when animals were 10 months old, at which time fibre diameter, fleece weight and body weight were recorded. Immune competence (IC-Comb) was defined as a composite phenotype based on the combined ranking of antibody-mediated (Ab-IR) and cell-mediated (Cell-IR) immune responses for each hogget. Rankings were derived from model residuals (observed minus predicted) obtained separately for Ab-IR and Cell-IR, using models that included age of dam and birth type as fixed effects and ewe-lamb age at measurement as a covariate. Residuals for each trait were standardised by dividing by their respective standard deviation, and IC-Comb was calculated as the mean of the standardised Ab-IR and Cell-IR residuals. The effect of ewe-lamb IC-Comb group (25% low, 50% medium and 25% high) on production, efficiency and health traits was analysed using a generalized linear model. Body weight at different ages, fleece weight, wool fibre diameter, rib eye area, backfat thickness, feed efficiency, methane emissions, feed intake and resistance to gastrointestinal parasites did not differ ($P > 0.05$) among ewe-lambs from different IC-Comb groups. These preliminary results indicate an absence of trade-offs between immune competence and relevant productive, efficiency and health traits in extensive grazing systems. This lack of antagonism supports the potential inclusion of immune competence as a novel phenotype in national breeding programs aimed at selecting sheep with an enhanced ability to develop adequate immune responses. However, because these results are not fully consistent with previous research, a larger database including multiple years of evaluation is required to confirm these initial findings.

Activity-based resilience indicators and their relationship with health in dairy cows

L. Büttgen[1], M. Van Der Sluis[1], R. De Mol[2], I. Van Dixhoorn[2], T. Fernandes Farias[1], E. D. Ellen[1]
[1] Wageningen University & Research, Animal Breeding and Genomics, 6700 AH Wageningen, Netherlands, [2] Wageningen University & Research, Animal Health and Welfare, 6700 AH Wageningen, Netherlands

Breeding objectives for dairy cows have been shifting from a production focus to more balanced breeding goals that also include aspects related to resilience. Resilience – the ability of animals to cope with short-term disruptions, including those caused by pathogens, through response and rapid recovery to their original state – is often assessed based on deviations in production traits. However, changes in production traits might be a later (i.e., 'slower') indicator of stressors occurring than behaviour-based indicators and are not available for the whole life span (e.g. before calving). Therefore, this study examines activity-based indicators in dairy cows and assesses whether these are informative for resilience. Activity data were collected on a total of 229 dairy cows from five different farms in the Netherlands. These cows were fitted with leg accelerometers, that recorded data on the number of steps taken (nStep), number of minutes per hour in which a cow walked (mWalk), minutes standing (mSta), the sum of mWalk and mStand (mSsta), minutes lying (mLie), number of times getting up (nUp), as well as neck accelerometers recording the neck activity (NeckAct). Moreover, the collected data on cows' positions in the barn over time were used to calculate distances moved by individual cows (Dist), based on raw data. The agreement between the different locomotion activity indicators (nStep, mWalk and Dist) was examined. Health data – available from previous research – consisted of clinical assessment and blood values (measured in week 1-5 after calving), which provided a total deficit score that could be separated into health components such as lameness, inflammations and metabolic aspects. The natural logarithm of variance (LnVar), the autocorrelation and skewness were calculated as potential resilience indicators, for each of the different activity measurements from the accelerometers using the R package EMOTIONS based on curves fitted with an ensemble model. The LnVar was corrected by the mean of the activity curve to account for the general activity level of the specific cow. The correlation between the activity-based indicators from the accelerometers and the different health scores was assessed. The analyses indicated a high agreement between nStep and mWalk ($r = 0.99$) as well as the LnVar calculated based on these traits, while the agreement between nStep and Dist was low to moderate. The highest correlation of an activity-based indicator with health scores was observed for LnVar corrected by the mean. The trait mSsta showed the highest positive correlations ($r = 0.51$) with health scores, albeit just slightly higher than for mSta ($r = 0.45$). In contrast, the correlations of the health scores with the autocorrelation and skewness were low or even negative for all considered traits, and for all other considered traits than mSsta and mSta the LnVar also showed low correlations with health scores. These results showcase the potential of activity-based patterns as resilience indicator traits to capture resilience to the transition phase, which cannot be captured using production-based indicators that may show a delayed response. The time a cow stands or walks seems to be the most promising measurement to build a resilience indicator trait. Such accelerometer-based indicators allow for large scale phenotyping and may have potential to be included in breeding programs to improve cattle resilience. This work was co-funded by the European Union's Horizon Europe Project 101136346 EUPAHW.

Circadian rhythm of feed intake and heritability estimates in Romane sheep divergently selected for feed efficiency

L. Riaboff[1], F. Tortereau[1], K. Biard[1], H. Lagarde[2], C. Marie-Etancelin[1]
[1] INRAE-GenPhySE, chemin de Borde rouge, 31326 Castanet-Tolosan, France, [2] INRAE-P3R, la sapinière, 18390 Osmoy, France

Selection for improved feed efficiency is widely implemented across livestock systems to reduce feed consumption and nutrient excretion but its effects on feeding behaviour remain poorly understood. In ruminants, less efficient animals tend to show stronger diurnal feed intake than more efficient ones. However, the relationship between feed efficiency and day-to-day consistency of feed intake, as well as the genetic determinism of these trait, remains unexplored. Therefore, this study aimed (i) to assess the ability of Romane sheep to exhibit a 24-h periodicity of feed intake according to sex and genetic line for feed efficiency using automatic feeder data and (ii) to estimate heritability of circadian traits. Between 2022 and 2025, about 650 Romane sheep (363 males and 284 females) were fed ad libitum (concentrate or forage) at INRAE P3R (https://doi.org/10.15454/1.5483259352597417E12). Each individual visit to the feeders (whatever the feed delivered) was recorded with intake, duration and hour. Studied animals belonged to two divergent lines selected for residual feed intake (RFI). The efficient line (RFI-) included 169 males and 113 females and the less efficient line (RFI+) 194 males and 171 females. In males, feed intake per visit was recorded in spring for 40 days between 3 and 5 months of age on a 100% concentrate diet. They were subsequently phenotyped in summer, between 6 and 8 months of age, for 40 additional days under a mixed forage diet. Females, sisters of the phenotyped males, were recorded only during these 40 days under forage conditions. A time-frequency approach (wavelet) was applied to hourly feed intake to detect 24-h periodicity. Wavelet analysis is widely used to identify rhythmic activity patterns in mammals by quantifying similarity between the observed signal and a sinusoidal function evaluated over periods and shifted along the time series. The percentage of days with detectable 24-h periodicity (hereafter circadian trait) was calculated for each individual over four periods: P1 and P2 corresponded to the first and second 20-day concentrate phases; P3 and P4 to the respective forage phases. Heritability of circadian trait in each period was estimated using a univariate animal model with Blupf90 software. For each period, animals were assigned a binary variable: 0 = no 24-h periodicity; 1 = at least one day with a 24-h periodicity. A Chi^2 test compared frequencies between RFI lines (R4.2.1). In males, a 24-hour periodicity was observed on fewer than 2% of days in P1 and on approximately 10% of days in P2. The percentage increased with age, with a 24-hour periodicity detected on 16% and 21% of days during P3 and P4, respectively. Heritability estimates of these traits were near 0 in P1, 0.24 ± 0.11 in P2, and reached to 0.19 ± 0.10 in P3 and 0.31 ± 0.11 in P4. In females, percentage of days with a circadian rhythm also increased from 17% to 20% in P3 and P4, respectively. Heritability was 0.41 ± 0.13 in P3 and 0.40 ± 0.14 in P4. Comparison between RFI lines showed sex-dependent trends in circadian feed intake rhythms. Among males, the proportion of animals showing a circadian feed intake rhythm did not differ between RFI lines, regardless of diet. In contrast, during the forage phase in females, a significantly greater proportion of RFI+ (46%) exhibited a circadian rhythm compared with RFI- (31%). This study showed that circadian feed intake patterns develop progressively with age in Romane sheep and that this trait is partly genetically-driven. Selection for feed efficiency had little effect on the circadian feed intake patterns.

Heritabilities of Nitrogen Use Efficiency and Nitrogen Loss for Norwegian Red cows vary over the course of lactation

N. Shoukat[1], A. Kidane[1], T. K. Belay[1], T. Meuwissen[1], B. Heringstad[1]
[1] Norwegian University of Life Sciences, Department of Animal and Aquaculture Sciences, NMBU, 1433 Ås, Norway

The environmental and economic pressures to reduce nitrogen surplus in livestock systems are increasing. It has already been documented that there is genetic variability in nitrogen use efficiency (NUE), but how phenotypic variance is partitioned into its causal components across the lactation cycle has not been previously explored in Norwegian Red cows (NRF). The objective of this study was to explore how genetic variance for NUE and nitrogen loss (NL) changes throughout lactation and to examine their genetic correlation. The data used for this study were collected from 1932 NRF cows across 16 herds located in different regions of Norway. The NUE is defined as the proportion of dietary nitrogen intake that is recovered in milk nitrogen output, expressed as a percentage, whereas NL is calculated as nitrogen intake minus nitrogen output in milk, expressed as kg/day. NUE and NL were calculated as 4–7-day averages using test-day records and data from the preceding six days. Descriptive statistics showed that the mean (± SE) of NUE and NL were 30.41% (5.77) and 0.37 kg/day (0.08), respectively. The phenotypic correlation between NUE and NL was -0.46. A random regression (RR) animal model was used to examine the genetic variability in NUE and NL across the lactation cycle. The fixed effects considered were Herd-Year-Season, parity, and days in milk (DIM), modelled with a 2nd-order Legendre polynomial; for the random additive genetic effect, DIM was considered as a 2nd-order Legendre polynomial, and residual effects were considered homogeneous. Pedigree information, consisting of 4,957,544 records, was narrowed to the last 5 generations (8950 animals) to construct the additive relationship matrix. The genetic variability in both NUE and NL did indeed change throughout lactation. The heritability of NUE decreased from 0.33 (SE = 0.037) at 5 DIM to 0.21 (SE = 0.033) at 30 DIM and stayed within the range of 0.10 (SE= 0.023) to 0.22 (SE = 0.034) until 320 DIM before rising to 0.33 (SE = 0.049) at 346 DIM. The heritability of NL stayed in the range from 0.07 (SE = 0.009) to 0.17 (SE = 0.03) between 20 DIM and 300 DIM, and then abruptly increased to 0.49 (SE= 0.03) at 340 DIM. To calculate the genetic correlation (rG) between NUE and NL, a bivariate repeatability animal model with the same fixed effect as RR model and random additive genetic/permanent environmental effects was used, estimating an overall rG = -0.571 (SE = 0.137), alongside three stage specific estimates across three DIM ranges; 5–120 days (rG = -0.66 ± 0.20), 121–240 days (-0.15 ± 0.22), and 241–346 days (-0.31 ± 0.46). Overall, the heritability of NUE was moderate in early lactation, declined and remained relatively low throughout mid-lactation, then increased again toward the end of lactation, whereas NL showed low-to-moderate heritability across most lactation, with an increase in late lactation. The rG between NUE and NL was strongly negative in early lactation and remained low to moderate from mid to late lactation. The RR model provided information on changes in genetic variability across the lactation cycle. But the model was applied to a dataset with a relatively few records per lactation (4 on average). Moreover, in the early and late stages of lactation, the data included relatively few observations. These limitations likely contributed to the increase in heritability for NUE and NL at the extremes of the lactation cycle. However, genetic variability for both NUE and NL across lactation stages highlights the potential to improve these traits through selective breeding in NRF cows.

Combining mechanistic energy allocation and genetic models to explore multiperformance in dairy sheep population

A. Irunal Veedu[1], F. Douhard[1], R. Rupp[1], J. Raoul[1,2]
[1] INRAE, GenPhyse, Université de Toulouse, INRAE, ENVT, F-31326, 31321 Toulouse, France, [2] Idele, 31 321 Castanet-Tolosan Cedex, 31321 Toulouse, France

Enhancement of dairy sheep multiperformance at the population level requires simultaneous progress in production and environmental traits, such as reducing enteric methane emissions per unit of milk. Mechanistic models explicitly represent the underlying biological functions that drive these traits and their trade offs, and can be run under many nutritional environments and management regimes to explore how alternative strategies affect lifetime performance. Genetic selection is another promising lever to enhance animal multiperformance at population level. Predicted gains are typically evaluated using additive genetic models in which animal performances are simulated based on the infinitesimal model. Combining these two types of models offers a promising approach to assess the benefits of selection strategies across diverse environments and to better account for potential trade-offs among traits. Mechanistic energy allocation models predict how animals acquire and partition dietary energy into maintenance, growth, body reserves and lactation day by day across their life and under diverse feeding conditions. This allocation pattern can be represented as an individual, genetically determined strategy that is heritable and can respond to selection. In this work, the energy acquisition and allocation coefficients are modelled as quantitative genetic traits and each ewe carries additive genetic values for these coefficients, which are transmitted through the pedigree. The distribution of these coefficients in the population is dependent on their mean and their phenotypic and genetic variances, provided as model inputs. For each ewe, the mechanistic model generates daily trajectories of feed intake, methane emissions, milk yield and body weight across multiple years and nutritional environments, which are aggregated into annual phenotypes such as cumulative methane, methane intensity, total milk yield and mature body weight. We then asked whether realistic levels of genetic variation in these output traits can be generated through genetic variation in a limited number of biologically interpretable input coefficients, and what ranges of heritabilities and genetic correlations are attainable. Preliminary analyses show that genetic variation in methane, milk and body weight can be successfully simulated by assuming heritable variation in a subset of acquisition and allocation coefficients related to intake level and allocation to lactation, whereas variation in other coefficients has negligible impact on these outputs. By tuning the magnitude of genetic variation in these key coefficients, the framework is able to reproduce a broad range of heritabilities and genetic correlations between methane, milk yield and body weight. This way, the model can be calibrated with values consistent with those reported in the literature. The combined mechanistic–genetic framework thus acts as a virtual breeding platform to test alternative selection strategies before field implementation. Thereby, it supports the design of breeding programs that contribute to the multiperformance of dairy sheep systems.

The Third State of the World report on Animal Genetic Resources: first insights

G. Leroy[1], P. Ajayi[1], P. Boettcher[1]
[1] Food and Agriculture Organization - FAO, Viale delle Terme di Caracalla, 00153 Roma, Italy

Drawing on a wide range of sources, including data on approximately 9 000 breeds reported in the Domestic Animal Diversity Information System (DAD-IS), official reports from 112 countries and 17 organizations, and contributions from more than 100 authors through thematic analyses and case studies, the Third State of the World report provides a comprehensive appraisal of the global status of animal genetic resources. Although modest progress has been made over the past decade in breed characterization and monitoring, breeding, conservation, and sustainable use, substantial challenges remain. Around 50 percent of livestock breeds are currently with unknown risk status, and over 60 percent of breeds with a known risk status are considered at risk. While animal identification is reported for more than 80 percent of cattle breeds worldwide, only about one third are subject to genetic evaluation, a proportion that has remained largely unchanged over recent decades. Country reports indicate increasing coverage of in situ conservation across major livestock species; however, ex situ conservation, particularly ex situ in vitro, continues to lag behind. Among the identified gaps, insufficient and increasingly constrained funding is consistently reported as the most critical and growing concern.

Reflections on genomic assessment of genetic variation and the future of the breed concept

G. Mészáros[1], P. Boettcher[2], D. Ouédraogo[3], P. Burger[4], L. Colli[5], I. Curik[6,7], K. T. Gebre[8], G. Gutierrez Reynoso[9], G. Leroy[2], C. Looft[10], R. Mrode[11], J. M. Mwacharo[12], K. Periasamy[13], A. Stella[14], Y. Utsunomiya[15], J. Windig[16], J. Sölkner[1], M. Wurzinger[1,17]

The concept of a breed is one of the defining characteristics of domestic livestock populations. The specific and specialized characteristics of breeds, and the associated within- and across-breed diversity, are prime determinants of long-term genetic gain for production and functional traits. Frequently, breeds have non-production functions and are part of the cultural heritage of ethnic groups or entire countries. Despite its paramount importance, the definition of "breed" within a livestock species remains unclear. One of the most popular definitions is "a breed is a breed if enough people say it is". While the elegant simplicity of this definition is appealing, other aspects must also be considered. With decades' worth of genomic data from a wide variety of livestock species, we can assess the genetic variation in established breeds, and in populations whose classification remains debated. From the administrative perspective, expectations and rules for breed acknowledgement can differ in various countries. While perspectives differ, certainly a verbal establishment of a breed is not enough. Consequently, genomics metrics and opinions on population characteristics of breeds are a continued source of discussion.

Establishing and scaling up breeding programmes under challenging environments

F. Phocas[1], J. L. Gourdine[2], H. Gilbert[3], V. Ducrocq[1], J. Raoul[3,4], M. Wurzinger[5]
[1] Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, [2] INRAE, ASSET, Petit-Bourg, 97170 Guadeloupe, France, [3] Université de Toulouse, INRAE, GenPhySE, Chemin de Borde Rouge, 31321 Castanet-Tolosan, France, [4] Idele, Chemin de Borde Rouge, 31321 Castanet-Tolosan, France, [5] Iowa State University, Ames, 50011 IA, United States

There is a wide variety of options for the design and implementation of breeding programmes (BPs). We conducted a thematic study, investigating 17 case studies, to outline a comprehensive roadmap for advancing BPs under challenging conditions (harsh environments, difficult market access…), targeting smallholder farms in low-input and extensive systems. Community-based BPs (CBBPs) have emerged in the last two decades as ways to jointly conserve and improve local breeds. Important features of these CBBPs are i) the livestock keepers' active participation, ii) the improvement of locally adapted breeds to reduce dependence on input, and iii) the consideration of locally available infrastructure and support options. CBBPs are promoted as a tool for the economic and livelihood development of smallholder farmers in low-input systems through genetic improvement of livestock. The 17 case studies were taken from interviews and examples from a literature review, including a diversity of species (chicken, small ruminants, cattle, buffalo, pig, llamas) and products (meat, milk, eggs, wool and cashmere) from different regions (Africa, Asia, Latin America and the Caribbean). Based on the case study analysis, we addressed strategies for scaling up BPs in challenging environments, highlighting 9 main issues and practical approaches to expand their reach and effectiveness while maintaining sustainability. Breeding activities necessitate substantial investments for the various stakeholders. Case studies demonstrate that BPs will always need external inputs (technical and/or financial support) to be sustainable. This also holds in high-income countries for numerous BPs that still receive public funding. Long-term BP success depends on strong stakeholder cooperation. A prerequisite for their success is the existence of a market that can make profitable livestock breeding and products. In low-income countries, scaling up BPs is challenging due to limited infrastructure, and lack of skilled personnel, legal frameworks, and public funding. For impact, BPs must align with local development stages and available resources, while improving herd management and value chain services. Scaling up BPs is essential i) to connect dispersed CBBPs and thus, ensure systematic recording and overcome the limitations of small herd sizes in genetic evaluations; and ii) to effectively disseminate improved animals to livestock keepers in remote areas. Otherwise, only a few livestock keepers can benefit from the progress achieved. A BP can expand vertically (scaling up by increasing the number of breeding males) or horizontally (scaling out by replicating elsewhere the BP). Both strategies are feasible for small ruminants, while intensifying male use via AI is rarely cost-effective. For large ruminants, AI is often the best option due to high costs and risks of natural service. In poultry, organisations, like World Poultry Foundation and Tropical Poultry Genetics Solutions, partner with private actors to supply improved breeds, scale chick production, establish brooding units, train specialists, and empower women farmers to raise birds for meat and eggs. Case studies were too rare to decipher general rules for other species. A country with national, regional or local BPs strengthens its food security and provides job opportunities. Scientists' support is needed to assist stakeholders in their R&D actions as well as in their capacity building.

The Evolving Role of the Private Sector in Livestock Breeding

C. Gonzales[1], Ç. Kaya[1], G. Cartick[1]
[1] European Forum of Farm Animal Breeders - EFFAB, Silkeborg 75, 2905 Capelle aan den IJssel, Netherlands

Over the past decade, the private sector has undergone a profound transformation in its approach to the management and use of animal genetic resources (AnGR). Once characterised primarily by productivity-driven selection, breeding companies and reproduction organisations across ruminants, pigs, poultry, aquaculture and insects have broadened their breeding objectives to encompass animal health and welfare, environmental sustainability, and the long-term maintenance of genetic diversity. This shift reflects both mounting societal expectations and an evolving regulatory and policy landscape at European and global levels. Drawing on the experience of EFFAB, this presentation explores how technological advances, governance frameworks, and the broader societal context have collectively reshaped private sector engagement with AnGR since the Second State of the World Report on Animal Genetic Resources for Food and Agriculture. Evidence is drawn from private sector's data and perspectives, offering a cross-species view of progress made, persistent gaps, and emerging priorities as seen from the breeding and reproduction sector. The presentation reflects on key developments in breeding objectives, the uptake of new genomic technologies and their implications for genetic diversity management, and the regulatory environment shaping private sector operations. Looking ahead, the presentation identifies future challenges and opportunities for the private sector in the context of the Global Plan of Action for Animal Genetic Resources. It argues that realising the private sector's full contribution to sustainable AnGR management will require more inclusive governance frameworks, greater recognition of existing industry accountability mechanisms such as the Code of Good Practices for Responsible and Balanced Breeding (Code EFABAR), and stronger public-private collaboration built on mutual trust and clear data-sharing conditions.

Progress, Gaps, and Future Challenges in Animal Genetic Resources Management in Europe from a National Coordinator Perspective

E. Sosin[1], N. Svertedal[2], S. J. Hiemstra[3], S. Stojanović[4], J. Tomka[5], G. Polak[1], A. Chełmińska[1]
[1] National Research Institute of Animal Production, Krakowska 1, 32-083 Krakow, Poland, [2] Norwegian Genetic Resource Centre, Postboks 115, NO-1431 Ås, Norway, [3] Wageningen University Research, Droevendaalsesteeg 4,, 6708 Wageningen, Netherlands, [4] Ministry of Agriculture, Forestry and Water Management, Omladinskih brigada 1, 11070 Belgrade, Serbia, [5] National Agricultural and Food Centre, Hlohovecká 2, 951 41 Nitra, Slovakia

Since publication of the Second Report on the State of the World's Animal Genetic Resources, AnGR management has shifted from largely descriptive assessments to more strategic, policy-oriented approaches. Major advances have been made in characterizing and monitoring livestock diversity through improved databases, phenotypic and genomic tools, and more systematic reporting. New EU legislation has embedded genetic resources more firmly in agricultural policy, raising visibility and responsibility at national level and increasing demand for evidence-based prioritization of at-risk breeds. A key milestone is the European Union Reference Centre for Endangered Animal Breeds (EURC-EAB), which provides scientific and technical support, promotes harmonization, strengthens cooperation among Member States, and reinforces the role of breed societies and the breeding industry in sustainable breeding programmes.Regional and international coordination has intensified. In Europe, the European Regional Focal Point for Animal Genetic Resources (ERFP) has strengthened collaboration, enabled knowledge exchange, and advanced a common AnGR Strategy for Europe, supporting more coordinated in situ and ex situ action. Expansion of the European Gene Bank Network for Animal Genetic Resources (EU-GENA) has further consolidated ex situ conservation, increasingly viewed as core risk management rather than a complementary measure. In parallel, reporting and coordination mechanisms are increasingly linked to wider biodiversity and rural-development agendas. Transboundary-breed management now requires closer alignment among countries, while small populations remain vulnerable—especially to infectious disease outbreaks—underscoring the need to reinforce gene banks and establish clear emergency procedures.Important gaps persist. Many local breeds remain endangered because of limited economic viability, weak incentives for diversified products, and underdeveloped market valorization mechanisms. Data gaps still constrain assessment of genetic diversity and adaptive potential. Although genomic technologies offer opportunities, uptake is uneven and often limited by resources and capacity; capacity building and practical decision-support tools are needed to translate genomics into routine breeding and conservation action. Ensuring effective stakeholder coordination and alignment with European and global frameworks remains challenging.Looking ahead, the National Coordinator's role is becoming more complex as climate change, disease risks, evolving production systems, and regulatory developments demand integrated, forward-looking action. Stronger links between conservation and sustainable use—including ecosystem management principles and recognition of ecosystem services—will help ensure AnGR support environmental resilience and human well-being. Priorities include digitalizing data systems and enabling rapid exchange, sustaining long-term gene bank infrastructure and operational capacity, strengthening cross-border cooperation, and improving emergency preparedness. Ultimately, future AnGR management will depend not only on technology, but also on coordination, coherent policy implementation, sustained investment, and efficient data sharing across sectors and countries.

European resilient livestock farming in a continuously changing world - Welcome & introduction

C. Lauridsen[1], J. Bérard[2]
[1] Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, [2] EAAP, Via G. Tomassetti 3, 00161 Roma, Italy

European livestock farming is going through a period of profound change. Geopolitical tensions and global trade disputes have disturbed feed supplies and reshaped market dynamics. At the same time, societal scrutiny over environmental impact, animal welfare and health is challenging the sector's legitimacy – particularly in Western Europe. Nevertheless, the livestock sector continues to play a vital role in Europe's food and nutrition security. It contributes to circular food systems, supports rural economies and provides essential nutrients. As pressures mount, the sector must innovate and engage with policy and society to secure its place in a more sustainable and resilient food future. How can Europe's livestock sector redefine its role and earn public trust while delivering sustainability and food security in an increasingly fragmented world? Most of the focus on livestock and climate change has been on emissions of greenhouse gases and opportunities to mitigate them. However, the impact of climate change on livestock agriculture is becoming increasingly important as extreme weather events become more frequent: temperature rise is approaching the 1.5 degree set in the Paris Agreement, longer periods of drought or intense rain are increasingly frequent too. In addition, EU livestock production is challenged due to the global situation as such, as e.g. feed prices may be highly influenced by the price and/or availability of the raw materials. One example is the situation experienced in Ukraine with the limited exportation of barley/wheat, and a similar situation could be experienced with the USA in relation to the export of e.g. soy protein/corn. The topic will address consequences of several factors in building resilient livestock systems, including land and water shortage, extreme heat for livestock farming and related operations, feed and food security/safety as well as lack of farmers to ensure future food production, social demands and how to minimize these impacts. Water and land requirement and resilience of livestock farming to a changing environment such as fodder availability, feed additives supply, capacity to adapt and cope with emerging diseases and other critical situations are already challenges faced by the farmers, and may be even further sharpen in the near future. The use of land and water in livestock production is under increasing scrutiny and the extreme weather events are dramatically affecting efficiency, livability and animal health, likely leading to displacements of some from farming areas and replaced by more resilient genetics and breeds. The uncertainty of climatic conditions is already dictating several changes in management practices, affecting more pronouncedly outdoor livestock systems (e.g. based on grazing areas), but also, and indirectly by influencing feed production (fodder and/or cereals, legumes, etc.), and putting systems sustainability at risk. The dramatic decrease and uncertainty on farmer generational renewal is a real problem and places future animal farming and livestock production in the EU in a difficult situation. This implicates higher food insecurity in the EU. The theme also intends to explore the implications for the upstream and downstream sectors, such as animal feeding and nutrition, breeding and medicines, food processors, etc., involving all sectors including industry (milk processors, slaughterhouses, feed companies).

The New Era is Now: Sustainable Livestock Through Global Collaboration

T. Tiensin[1]
[1] *FAO, Animal production & Health Division, Viale delle Terme di Caracalla, 00153 Rome, Italy*

Global dynamics, particularly population growth, rising incomes and rapid urbanization, have contributed to an increased demand for animal protein, making the livestock sector one of the fastest growing agricultural sectors. This means that the livestock sector is central to agrifood system transformation and plays a key role in rural development through economic growth, poverty reduction and its contribution to better livelihoods. Livestock provides food, fibre and a wide range of animal products, as well as draught power, and in most developing countries livestock provides smallholder farmers with a substantial proportion of their income. By serving as productive assets and sources of household nutrition, livestock can offer a pathway to poverty reduction and economic well-being, enhancing the resilience and adaptability of rural communities. Although the livestock sector presents numerous opportunities, it also faces significant challenges. If not properly managed, the rapid growth in the livestock sector can increasingly threaten natural resources, such as water, land and soil. The livestock sector is under scrutiny for the greenhouse gas emissions it generates, contributing to climate change. Livestock production can also impact biodiversity through expansion of the sector, changes in land use and deforestation, contributing to the loss of natural habitats and the fragmentation of ecosystems. Drawing on FAO's work across diverse regional contexts, this presentation provides a global overview of the main opportunities and challenges facing livestock systems today. It places particular attention on the role of youth, highlighting that as rural populations age and fewer young people enter the sector, attracting, empowering, and retaining the next generation of livestock keepers becomes essential for ensuring innovation, resilience, and the long-term sustainability of livestock systems.

Navigating the Future of Animal Protein in a Changing Global Landscape

E. Gocsik[1]
[1] Rabobank, Croeselaan 18 (UC G7), 3521 CB Utrecht, France

Global demand for animal protein is expected to grow over the coming decade, driven by population growth and rising income levels. This expansion will be concentrated primarily in Asia, Africa, and the Middle East. In contrast, Europe will experience slow income growth alongside a stable or slightly declining population, resulting in softening demand for animal protein. Europe's competitiveness in global markets will come under increasing pressure as production costs rise, largely due to tighter environmental and social regulations. Traditional volume-driven, export-focused business models will become less viable, creating the need for new value-creating approaches. To remain successful, animal protein companies will need to shift from prioritizing volume to delivering higher value and strengthening their focus on European consumers. This transition will be complicated by declining animal numbers as environmental constraints tighten, greater volatility stemming from geopolitical tensions, and continued dependence on global markets for key inputs. These pressures will accelerate industry consolidation. In such a challenging environment, innovation and rapid adoption of new technologies across animal protein supply chains will become more critical than ever.

Ensuring EU feed security and safety in a rapidly changing global environment

R. Hayler[1], J. Seifert[2], A. Van Den Brink[3]
[1] BASF SE, Regulatory Affairs & Quality Compliance Nutrition Ingredients, G-ENN/RQ - J660, D-67056 Ludwigshafen, Germany, [2] FEFANA asbl, Avenue des Arts 56, B-1000 Brussels, Belgium, [3] FEFAC aisbl, Rue de la Loi, 223, B-1040 Brussels, Belgium

In an increasingly volatile geopolitical, economic and environmental context, ensuring the security and safety of feed supplies has become a strategic priority for the European Union. The feed sector stands at the heart of the agri-food chain, playing a critical role in safeguarding animal health, supporting sustainable livestock production and contributing to food security for European citizens. Against this backdrop, FEFANA and FEFAC, as the two leading trade associations of the EU feed chain, jointly present an in-depth analysis of the challenges and opportunities shaping EU feed security and safety in a rapidly changing global environment. The presentation will explore the multifaceted pressures currently affecting global feed supply chains, including geopolitical instability, climate change, trade disruptions, evolving regulatory frameworks, and increasing sustainability expectations. These factors have heightened risks related to the availability, affordability and quality of feed, while simultaneously placing greater demands on safety and environmental performance. The COVID-19 pandemic and ongoing geopolitical tensions have further exposed vulnerabilities within global logistics networks, underscoring the urgent need for resilience, diversification and strategic autonomy. FEFANA and FEFAC will outline how the European feed sector is responding to these challenges through innovation and close collaboration across the supply chain. Key topics include strengthening feed safety systems, improving risk assessment and crisis preparedness, and fostering responsible sourcing strategies. Particular attention will be given to the role of feed additives, technological innovation and digitalisation in improving feed efficiency, animal health and environmental outcomes, while reinforcing food and feed safety standards. The presentation will also examine the implications of EU policy initiatives and evolving trade and sustainability regulations, on feed security and competitiveness. While ambitious sustainability goals offer opportunities for innovation and transformation, they must be aligned with realistic implementation pathways that preserve supply stability, economic viability and international competitiveness. FEFANA and FEFAC advocate for coherent, science-based and globally aligned regulatory frameworks that support both safety and sustainability without undermining the resilience of the feed sector. Furthermore, the presentation will highlight the strategic importance of international trade and partnerships in securing diversified and reliable feed ingredient supplies. It will emphasize the need for open, rules-based trade, regulatory cooperation, and alignment of safety standards to maintain access to global markets and mitigate supply risks. At the same time, opportunities to enhance EU protein self-sufficiency, circular economy approaches, and alternative feed resources will be explored as complementary strategies to strengthen long-term resilience. By bringing together the perspectives of feed additive producers and compound feed manufacturers, this joint presentation will deliver a comprehensive and forward-looking vision for ensuring EU feed security and safety. It will provide policymakers, stakeholders and industry leaders with concrete recommendations to build a resilient, innovative and sustainable feed system capable of supporting Europe's food security ambitions in an increasingly complex and uncertain global environment.

Exploring the Missing Middle: From Polarization to Systemic Responsibility in Europe's Protein Transition

M. Moretti[1]
[1] *University of Pisa, Agriculture, Food and Environment, Del Borghetto, 80, 56124 Pisa, Italy*

Europe faces a striking paradox: it is a net exporter of animal proteins, while its internal consumption levels largely exceed nutritional recommendations. In this context, the protein transition is often framed in stark and simplified terms. One hypothetical response would be to advocate for a drastic and immediate reduction in livestock production and consumption—full stop—as if complexity could be resolved through a single corrective measure. This scenario is not presented as a realistic or desirable policy option, but as a heuristic extreme that exposes the limits of reductionist thinking. At the opposite end, a business-as-usual trajectory relies on incremental efficiency gains to mitigate impacts without fundamentally altering the system. Both narratives—radical contraction and incremental optimization—contain elements of truth. Yet both risk offering deceptively simple answers to a structurally complex socio-ecological challenge. This keynote argues that the debate—and much of the associated research—is trapped in a polarization that obscures a crucial analytical and political space: the "missing middle" between these extremes. On the production side, sustainability is often equated with efficiency—producing more with fewer inputs and lower emissions. On the consumption side, responsibility is largely placed on individual dietary change. What disappears in this divide is a systemic understanding of livestock systems as territorially embedded, multifunctional socio-ecological systems operating within diverse environmental, economic, and institutional contexts. Exploring the missing middle requires reframing livestock not only as a source of food commodities, but also as a provider of ecosystem services, social value, and territorial cohesion. Livestock systems contribute to landscape management, biodiversity, nutrient cycling, employment, and cultural heritage. In many inner and marginal rural areas of Europe, livestock farming represents the backbone of local economies and a key factor in preventing land abandonment and demographic decline. A uniform reductionist approach—if implemented without differentiation—would risk generating uneven territorial consequences while failing to address structural imbalances along the value chain. Adopting a systemic perspective is not only an analytical shift—it has implications for European policy dynamics. It challenges sectoral silos separating agricultural productivity, environmental protection, public health, rural development, and trade policy. It questions instruments that reward efficiency without accounting for territorial externalities and multifunctionality, and it reveals the limits of governance approaches that allocate responsibility primarily to farmers or consumers. A systemic approach instead calls for shared responsibility across the value chain and governance levels. It implies greater coherence between the Common Agricultural Policy, the Green Deal, the Farm to Fork Strategy, climate and biodiversity regulations, cohesion policy, and trade frameworks. It requires valuation mechanisms capable of recognizing ecosystem and social services alongside commodity outputs, and governance arrangements enabling coordinated trade-offs. Drawing on insights from the European projects PATHWAYS and Re-Livestock, this keynote reflects on how integrated assessment and multi-actor engagement can help overcome research polarization and inform more coherent, territorially sensitive, and socially legitimate policy pathways for Europe's protein transition.

The social and economic challenges to farmers – how can generational renewal be achieved?

K. Wosnitza[1]
[1] Arbeitsgemeinschaft bäuerliche Landwirtschaft AbL eV, Norderfeld 12a, 25864 Löwenstedt, Germany

The generational transition in agriculture represents a central challenge for the future of rural areas. In addition to income volatility, rising land and lease prices, and high capital requirements, clear differences between types of farms are evident. Larger farms are often confronted with significant financial burdens and investment risks when transferring ownership, while smaller, family-run farms have only limited opportunities to invest in modern technologies, which restricts their competitiveness. At the same time, their workload is particularly high due to the large share of family labor, resulting in long working hours and limited flexibility. In addition, political uncertainty—particularly with regard to animal welfare and environmental regulations—complicates long-term investment decisions. At the same time, markets must provide viable economic perspectives; a lack of profitability in certain production sectors is already leading to exit processes. Another decisive factor is access to land, which represents a major barrier, especially for new entrants. By incorporating the perspective of a family farmer and drawing directly on the speaker's practical experience, the contribution shows that generational renewal requires differentiated solutions that take economic, social, and environmental dimensions into account. A key aspect is that agricultural farms are not only confronted with increasing requirements, but also need the perspective of being able to implement their own values. For many young people—especially newcomers to farming as well as partners from outside the agricultural sector—issues such as socio-economic sustainability, animal welfare, and biodiversity are becoming increasingly important. Financial support instruments should therefore be understood less as traditional subsidies and more as compensation for public goods that are not adequately remunerated by the market. Against this background, the question arises as to the future development pathways of agricultural farms: between 14,000-liter cows and cow-calf rearing on pasture, between climate-friendly barns and biodiversity conservation, between manager and farmer, family and business. Do viable hybrid forms emerge—or does this increase the risk of overload? In light of discussions about workload and mental health, the question also arises whether, and under what conditions, young people are willing to pursue this path and how advisory systems must be designed to support them effectively.

EU Policy change related to the vision for agriculture and food, including simplification of EU rules and bureaucracy and comprehensive EU livestock strategy

B. Misonne[1]
[1] European Commission, DG AGRI, Rue de la Loi, 120, 1000 Brussels, Belgium

The Commission's Vision for Agriculture and Food recognises livestock as an essential component of EU agriculture and the food value chain (https://agriculture.ec.europa.eu/overview-vision-agriculture-food/vision-agriculture-and-food_en). The sector makes a major contribution to the EU economy, sustains rural communities, and supports landscape management and environmental preservation. The EU livestock sector is currently at a crossroads and faces a complex set of challenges which vary depending on different factors (size, sector, etc.) and across Member States: declining herd numbers and farm closures, persistently low profitability and weak economic viability, growing concerns about farmers' well-being, the sector's environmental and climate footprint, intensifying trade and market competition, animal health and welfare risks, and uneven territorial impact. At the same time, these challenges are driving transformation and opening up new opportunities for strengthening the sector's competitiveness and long-term sustainability. Innovation in breeding, feed efficiency, animal health and welfare, and digital technologies are all improving productivity and reducing environmental impacts. Growing consumer demand for high-quality, sustainably produced and regionally differentiated livestock products creates added-value market opportunities. Resource efficiency and environmental and climate performance are being further improved thanks to: (i) the development of circular bioeconomy models, including better nutrient management; (ii) manure valorisation; (iii) integration with crop systems; and (iv) more being made of the link between livestock production and the maintenance of grasslands. A long-term vision is needed to ensure that the EU livestock sector is crisis resilient, globally competitive, sustainable in all dimensions and reflects Europe's territorial diversity. Against this backdrop, the Commission has included a livestock strategy with elements on animal welfare as a key initiative in its work programme for 2026 (https://commission.europa.eu/strategy-and-policy/strategy-documents/commission-work-programme/commission-work-programme-2026_en). It is intended to be delivered together with a protein plan to make the EU protein system more resilient and sustainable.

European resilient livestock farming in a continuously changing world - Panel discussion

Comparison of milk mid-infrared spectra and fatty acid-based models for predicting methane emissions

A. Köck[1], K. Linke[1], C. Schmid[2], F. J. Auer[2], M. Mayerhofer[1], J. Sölkner[3], T. Guggenberger[4], G. Terler[4], A. Steinwidder[4], T. Ettle[5], V. Huber[5], E. Gerster[6], C. Egger-Danner[1]

[1] ZuchtData EDV-Dienstleistungen GmbH, Dresdner Str. 89/18, 1200 Vienna, Austria, [2] LKV Austria, Dresdner Str. 89/18, 1200 Vienna, Austria, [3] University of Natural Resources and Life Sciences, Vienna (BOKU), Department of Agricultural Sciences, Institute of Livestock Sciences, Gregor-Mendel-Str. 33, 1180 Vienna, Austria, [4] HBLFA Raumberg-Gumpenstein, Raumberg 38, 8952 Irdning-Donnersbachtal, Austria, [5] Bayerische Landesanstalt für Landwirtschaft, Institut für Tierhaltung, Tierernährung und Futterwirtschaft, Prof.-Dürrwaechter-Platz 2, 85586 Grub-Poing, Germany, [6] Landwirtschaftliches Zentrum Baden-Württemberg, Atzenberger Weg 99, 88326 Aulendorf, Germany

Enteric methane (CH4) emissions were predicted from milk-derived information using data collected on 16 commercial dairy farms in Austria. Methane was recorded with the GreenFeed system, and corresponding milk samples were analyzed using mid-infrared (MIR) spectroscopy. Farms operated under comparable feeding regimes based on grass and maize silage, with varying concentrate supplementation and no grazing. The final dataset included 807 records from 604 cows. Two partial least squares regression approaches were evaluated. The first model used the milk MIR spectral information, whereas the second relied on milk composition traits, including 14 individual fatty acids (FA) along with fat%, protein% and lactose%. In addition, milk yield, parity and stage of lactation were included as predictors. Under 5-fold cross-validation, predictions based solely on MIR spectra achieved moderate accuracy ($r = 0.52$; $R^2 = 0.27$) and performed better than models relying only on FA profiles ($r = 0.42$; $R^2 = 0.18$). Expanding the FA model to include major milk components resulted in a small improvement ($r = 0.44$; $R^2 = 0.20$). When animal-related variables (milk yield, parity, lactation stage) were included, predictive performance increased markedly and reached comparable levels for both approaches (MIR: $r = 0.61$, $R^2 = 0.38$; FA: $r = 0.61$, $R^2 = 0.37$). Validation across farms using a leave-one-farm-out cross validation yielded slightly reduced prediction accuracies and highlighted between-farm variability. The highest performance in this scenario was obtained when all predictors were combined (MIR-based model: $r = 0.56$, $R^2 = 0.33$; FA-based model: $r = 0.58$, $R^2 = 0.35$). In summary, milk MIR spectra and FA composition captured only a part of the variability in CH4 emissions, suggesting that they primarily reflect the underlying metabolic status. Improving prediction accuracy will require additional predictors and advanced modeling approaches to better capture the complex biological, nutritional and environmental drivers of CH4 emissions. Additional analyses are planned, using combined data from commercial and research farms.

Phenotypic and genetic prediction of methane emissions from milk mid-infrared spectra in Norwegian Red dairy cattle

G. Difford[1], B. Heringstad[1,2], K. Bakke[2], A. Gjuvsland[2], G. Gorjanc[3], J. Jenko[2]
[1] Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Oluf Thesen vei 16, 1430 Ås, Norway, [2] Geno SA, Storhamargata 44, 2317 Hamar, Norway, [3] The University of Edinburgh, The Roslin Institute, Easter Bush Campus Midlothian, EH25 9RG Edinburgh, United Kingdom

Milk mid-infrared (MIR) spectroscopy is routinely collected in dairy recording and has been proposed as a low-cost indicator for enteric methane (CH_4) emissions. However, the robustness of MIR-based CH_4 prediction across herds remains uncertain, and phenotypic prediction accuracy alone may not reflect its value for genetic improvement because MIR spectra themselves are heritable traits. The objective of this study was therefore to evaluate both the phenotypic robustness and genetic relevance of MIR-based prediction of methane emissions in Norwegian Red dairy cattle. Methane emissions were recorded using GreenFeed systems in 14 commercial Norwegian dairy herds from 2020 to 2024. Milk MIR spectra from routine test-day recordings were matched with daily CH_4 phenotypes within ±5 days of each test day, resulting in 10,218 matched observations from 1,506 cows. Methane production was predicted from 899 MIR wavenumbers using partial least squares regression. Prediction performance was evaluated using five-fold cross-validation with cow-level blocking and leave-one-herd-out validation to assess transferability across herds. Genetic parameters for CH_4 production and MIR wavenumbers were estimated using pedigree-based animal models. Prediction accuracy was moderate when evaluated with cow-level cross-validation ($R^2 = 0.31$), but decreased substantially when validated across herds ($R^2 \approx 0.05$), indicating limited transferability of MIR-based phenotypic prediction equations under commercial conditions. Heritability estimates for MIR wavenumbers ranged from 0.00 to 0.30, demonstrating substantial additive genetic variation within the MIR spectrum. Genetic correlations between MIR wavenumbers and CH_4 production ranged from −0.41 to 0.50, suggesting that specific spectral regions capture genetic variation associated with methane emissions. Although MIR spectra showed limited ability to predict methane emissions phenotypically across herds, they contained heritable variation and exhibited moderate genetic correlations with CH_4 production. These results suggest that MIR spectra may be more useful as genetically informative indicator traits than as direct phenotypic predictors of methane emissions. Incorporating MIR-derived information into genetic evaluations could therefore contribute to breeding strategies aimed at reducing enteric methane emissions in dairy cattle. This work was supported by the Research Council of Norway (projects 309451 and 346741).

Biological validation of MIR phenotyping for intake, nitrogen efficiency and methane production along the lactation curve in dairy cows

M. Frizzarin[1], E. Manzocchi[2], A. M. Reiche[2], P. Schlegel[2,3], G. Lazzari[2], M. Tretola[3], F. Schori[2], F. Dohme-Meier[2], C. Kasper[1]

[1] Agroscope, Animal GenoPhenomics, Tioleyre 4, 1725 Posieux, Switzerland, [2] Agroscope, Ruminant Nutrition and Emissions, Tioleyre 4, 1725 Posieux, Switzerland, [3] Agroscope, Swine Research Group, Tioleyre 4, 1725 Posieux, Switzerland

Dry matter intake (DMI), nitrogen use efficiency for milk production (NUE), and enteric methane (CH4) production are key traits to improve sustainability in dairy production but remain difficult to measure routinely on farms. Milk mid-infrared (MIR) spectroscopy offers a low-cost phenotyping opportunity; however, its biological validity across lactation and parity still needs to be evaluated. Data were collected at the Agroscope experimental farm in Posieux between 2015 and 2024, including milk MIR spectra, feed intake, diet composition and automated head-chamber methane measurements. NUE was calculated by dividing milk nitrogen yield by nitrogen intake. To reduce the effects of daily variation, DMI and NUE were averaged across ±2 days and CH4 across ±5 d of milk sampling. We tested prediction models including linear regression, partial least squares regression (PLSR), and neural networks (NN), and evaluated them under 4-fold cross-validation, each including different sets of features combined with milk MIR data. The best model for each trait was applied to 9,975 historical milk MIR spectra to obtain estimated trait values for DMI, NUE and CH4. Prediction accuracy was moderate (DMI: R_2=0.64; NUE: R_2=0.56; CH4: R_2=0.52), and NN consistently outperformed PLSR models ($P < 0.05$). Including MIR information improved prediction of NUE and CH4 compared with animal information alone ($P < 0.05$). To test the biological validity of the longitudinal patterns of predicted DMI, NUE and CH4 along the lactation curve and across parities, the effects of lactation stage and parity were analysed using mixed-effects models. Indeed, the predicted traits reproduced biologically expected patterns: DMI increased to mid-lactation and declined thereafter, CH_4 rose rapidly after calving and stabilised, while NUE decreased across lactation. Multiparous cows showed higher intake and methane production throughout lactation, whereas their NUE exceeded primiparous cows only in early lactation. Correlations between residuals for predicted NUE and DMI as well as NUE and CH4 were near zero, but moderate (0.44) between DMI and CH4. These results demonstrate that MIR spectroscopy captures meaningful biological signals and can provide scalable longitudinal indicators of feed efficiency and environmental impact. Milk spectra therefore represent a promising scalable phenotyping tool for individual monitoring and genetic improvement of sustainability traits.

Optimizing methane emission prediction using cattle faecal near-infrared spectroscopy across confinement and grazing systems

S. Jeon[1], D. Andueza[1], N. Baleret[1], C. Martin[1]
[1] INRAE, UMRH, Rte de Theix, 63122 Saint-Genès-Champanelle, France

As concerns regarding enteric methane emissions (eCH4) intensify, numerous studies have focused on mitigation strategies in cattle production systems. The development of effective mitigation approaches requires accurate measurement of eCH4. Faecal near-infrared spectroscopy (fNIRS)-based prediction models have gained increasing attention as a non-invasive technique that can be applied to cattle without restricting their behaviour. However, limited information is available on the optimal duration of eCH4 data collection required to optimize the performance of fNIRS-based prediction models when the GreenFeed system is applied to collecting eCH4 data. Therefore, this study aimed to determine an appropriate eCH4 data collection period under contrasting production environments (i.e., indoor and grazing systems), based on the repeatability (R) of eCH4 measurements obtained using GreenFeed and the predictive performance of the fNIRS-based model. A total of 36 suckling cows conducted under indoor (P1) and grazing (P2) conditions for 105 days each. Methane emissions were measured using two GreenFeed® units simultaneously. Repeatability of eCH4 was calculated as the ratio of the animal variances to the sum of animal variances and residual error using data collected up to 100 days prior to faecal sampling into 1-, 2-, 4-, 5-, 10-, 20-, 25-, and 50-day intervals. One spot faecal sample per animal (100 g fresh weight) was collected either during natural defecation or manually from the rectum on the end of each period. Samples were subsequently dried (72h, 60°C) and ground (1-mm sieve) prior faecal reflectance spectral acquisition between 400 to 2500 nm (0.5 nm intervals) from a FOSS DS2500 instrument. Partial least squares (PLS) regression models were developed using eCH4 emission data averaged over periods ranging from 1 to 50 days prior to faecal sampling. Cross-validation errors were then compared across models. A total of 13,324 eCH4 data were recorded in P1 (419 ± 105.0 g/day), and 5,613 data were recorded in P2 (261 ± 86.2 g/day). Based on R analysis, P1 achieved stable repeatability after more than 10 days of eCH4 data collection (R = 0.73). In contrast, P2 showed a progressive increase in R with longer data collection periods, reaching a maximum R of 0.83 after 50 days. In comparison, P1 reached this level of R (R = 0.83) after 25 days. When the PLS prediction models were evaluated, the root means square error of cross-validation (RMSECV) stabilized after 2 days in P1 (13.5%). In contrast, RMSECV in P2 decreased steadily with increasing data collection length, reaching the lowest value when 50 days of data were used (RMSECV = 10.9%); P1 reached this comparable level of prediction error (RMSECV = 11.0%) after 9 days. Taken together, the R and PLS results indicate that approximately 10 days of data collection are sufficient under indoor condition, whereas more than 50 days are required under grazing condition. In conclusion, under our experimental design, indoor systems required substantially fewer days to achieve stable R values and prediction accuracy than grazing systems. As this study was designed as a proof of concept and involved only 36 animals, further validation using a larger population across more diverse production systems of cattle is warranted.

Faecal NIRS and its ability to predict digestive methane emissions in cattle supplemented with 3-NOP and Asparagopsis taxiformis additives.

Methane (CH4) has a high global warming potential in the atmosphere. In ruminants, CH4 is mainly produced by a specific microbial population (archaea methanogens) during the digestive process in the rumen. Current methods for quantifying individual digestive CH4 emissions are difficult to implement under commercial farming conditions. Near-infrared spectra (NIRS) can be obtained from bovine faecal samples, which are an unabsorbed product of the digestion process and a universal matrix. Since CH_4 and faeces are produced during digestion, these spectra could potentially be used to detect the use of anti-methanogenic additives (AMA) and predict digestive CH_4 emissions. This work aimed to: i) evaluate the potential of faecal NIRS to detect effects of AMA supplementation in cattle diet; ii) test existing predictive models of CH4 emissions from faecal NIRS of cattle supplemented or not with AMA. This work was based on three previous experiments (Exp.) on Holstein dairy cows (n = 43; within Exp. 1 and 2) supplemented with 3-nitrooxypropanol (3-NOP; 60 mg/kg DM), and Angus beef young bulls (n = 20; Exp. 3) supplemented with Asparagopsis taxiformis macerated oil (Bromoil; 25 mg/kg DM). Individual data on CH4 were acquired using respiration chambers (Exp. 1) or GreenFeed (GF) units (Exp. 2 and 3). One spot faecal sample from each animal (100 g fresh weight) was collected either during natural defecation or manually from the rectum during the same week as CH4 measurement. Faecal samples were dried (60 °C, 72 h) and ground (1 mm) prior to NIRS analyses (between 400 to 2500 nm; Foss DS2500 instrument). For each experiment, the faecal NIR spectra of the treatments were pairwise compared (control vs. 3-NOP in Exp. 1 and 2, or control vs. Bromoil in Exp. 3). Observed CH4 emissions (g/day) were lower on average by 32% and 23% in animals fed 3-NOP, and by 67% in animals fed the Bromoil. An independently obtained partial least squares CH4 prediction model was used to predict CH4 emissions from Exp. 1. This model was built from a database of n = 342 spectral values of cattle faeces (150 dairy, 192 beef) and associated CH4 emission data recorded using GF. The pairwise comparisons demonstrated that faecal NIRS successfully identified differences in all animals fed diets supplemented with AMA. However, the predicted CH4 values from the existing model did not align with the observed CH4 measurements (in Exp. 1). The root mean square error of prediction (RMSEP) was 174.7 g/day for the 3-NOP treatment and 75.7 g/day for the control treatment. These values were mainly explained by the bias (160.9 vs -3.9 g/day for 3-NOP and control, respectively). Specific prediction models were then developed for the 3-NOP supplemented cows in Exp. 1 and 2, reducing the root mean square errors of cross-validation to 30.7 and 21.7 g/day, respectively. For Exp. 3, model calibration is ongoing. This preliminary work highlights the potential of faecal NIRS to predict CH4 emissions from cows supplemented with AMA. Mid-infrared prediction and genetic analyses of serum metabolites for evaluation of metabolic health in dairy cows

S. Gruber[1], G. Terler[2], A. Steinwidder[2], T. Guggenberger[2], A. Köck[3], H. Schwarzenbacher[3], C. Egger-Danner[3], B. Fuerst-Waltl[1], J. Sölkner[1]

[1] BOKU University, Department of Agricultural Sciences, Gregor-Mendel-Strasse 33, 1180 Vienna, Austria, [2] Agricultural Research and Education Centre Raumberg-Gumpenstein, Raumberg 38, 8952 Irdning-Donnersbachtal, Austria, [3] ZuchtData EDV-Dienstleistungen GmbH, Dresdner Strasse 89, 1200 Vienna, Austria

Serum metabolites are relevant indicators to both assess and prevent metabolic and nutritional disorders of dairy cows during early lactation. For instance, β-hydroxybutyrate (BHB) or non-esterified fatty acids (NEFA) are used to diagnose ketosis, glucose to assess the energy status, or aspartate aminotransferase (AST) to evaluate liver function and metabolic stress. Serum metabolites are, hence, useful traits for herd management and genetic evaluation systems aiming to improve metabolic health of dairy cows. However, routine measurement is challenging in commercial farms due to cost and labour requirements. A potential alternative is the prediction from milk mid-infrared (MIR) spectra. The aim of this study was to develop prediction equations for a range of serum metabolites using MIR spectroscopy and evaluate corresponding genetic parameters. The dataset comprised 3,293 records of different serum metabolite concentrations collected on an Austrian research farm between 2014 and 2020. Partial least squares regression analysis was applied to calibrate prediction equations, utilizing a selection of 212 MIR spectra. Prediction accuracy was evaluated based on different validation scenarios, including a leave-one-cow-out and a leave-one-year-out validation approach. Subsequently, developed prediction equations were applied on a spectral dataset collected within the routine milk recording system of Austria, resulting in 51,847 MIR-spectra-predicted serum metabolite records of 23,909 Fleckvieh dairy cows with available genotype and health diagnosis data. For estimation of heritabilities and genetic correlations univariate and bivariate repeatability animal linear mixed models were applied. In the leave-one-cow-out validation, the prediction equations for BHB, urea, and NEFA obtained the highest prediction accuracy, with R^2 values of 0.79, 0.60, and 0.54, respectively. Glucose, cholesterol, bilirubin, AST, and triglycerides showed lower, but still good, predictive performance, with R^2 values of 0.42, 0.35, 0.31, 0.22, and 0.20, respectively. Performing the leave-one-year-out validation approach, showed marginally lower prediction accuracies overall. The heritabilities of the MIR-predicted serum metabolites were moderate and ranged between 0.08 and 0.18. Genetic correlations between MIR-predicted metabolites and health diagnoses varied depending on the metabolite considered, ranging from weak to strong. The results indicate that prediction equations from milk MIR spectra present a high-throughput phenotyping approach for deriving serum metabolite concentrations with moderate to high accuracy. The MIR-predicted metabolites exhibit moderate heritabilities and therefore have the potential to serve as novel traits for genetic evaluation systems aimed at breeding healthier dairy cows.

Improving milk mid-infrared prediction of dairy cow chronic stress biomarkers using machine learning and deep learning

H. Simon[1], C. Grelet[1], S. Franceschini[2], F. Dehareng[1]
[1] Centre wallon de Recherches agronomiques, Chau. de Namur 24, 5030 Gembloux, Belgium, [2] Gembloux Agro-Bio Tech Université de Liège, Pass. des Déportés 2, 5030 Gembloux, 5030 Gembloux, Belgium

Animal welfare is a major societal concern, with 91% of European citizens considering it important. Chronic stress in dairy cows affects health, reproduction, and productivity, yet no routine monitoring method exists. Mid-infrared (MIR) spectroscopy, already used during milk recording, offers a cost-free opportunity to develop such a tool. Grelet et al. (2025) predicted two chronic stress biomarkers — hair cortisol (pg/mg) and blood fructosamine (µmol/L) — from milk MIR spectra in 1,442 cows from multiple European herds, using partial least square (PLS) regression, pls-discriminant analysis (PLS-DA) and support vector machine (SVM), with limited performance (coefficient of determination; $R^2 \leq 0.20$). Building on these results, we hypothesise that the biological pathway linking chronic stress to milk composition involves non-linear relationships that linear chemometric methods cannot adequately capture. This study evaluates whether machine learning and deep learning approaches can enhance MIR-based prediction of hair cortisol and blood fructosamine on the same dataset (N = 1,442; 212 wavenumbers after first-derivative preprocessing). The original PLS, PLS-DA and SVM models were first reproduced in Python. Random Forest, Gradient Boosting and ElasticNet were then applied for quantitative prediction; Random Forest, Gradient Boosting and L1/L2-regularised logistic regression with class-imbalance strategies were used for qualitative low/high classification (83/17% ratio for cortisol). In parallel, neural network architectures were explored: multi-layer perceptrons and one-dimensional convolutional neural networks designed to capture correlations between neighbouring wavenumbers. Phenotypic covariates (days in milk, parity, milk yield, breed, hair colour) were tested as additional predictors. All approaches were compared under the same herd-based threefold cross-validation as the original study, ensuring evaluation on unseen herds. Preliminary results show contrasting patterns between the two biomarkers. For fructosamine, Random Forest improves quantitative prediction over PLS (R^2, 0.06 → 0.15; RMSE, 33.9 → 32.5 µmol/L), supporting the presence of an exploitable non-linear MIR signal. For hair cortisol, no non-linear regressor outperforms PLS ($R^2 \leq 0.05$ vs 0.08), but a class-balanced logistic model raises the recall on the high-stress class from 18% to 61%, at the cost of overall accuracy (82% → 70%; balanced accuracy 0.56 → 0.66). Deep architectures do not yet outperform tree-based methods on this sample size. These results are still being refined through further hyperparameter tuning and improved deep-learning training protocols, and will be discussed in relation to the initial non-linearity hypothesis, biological interpretability of predictive spectral regions, and feasibility for routine implementation within existing milk recording infrastructure. In conclusion, non-linear machine learning meaningfully improves MIR-based prediction of blood fructosamine and provides a more sensitive qualitative readout for hair cortisol, although quantitative cortisol prediction remains challenging across all tested methods. This refines the original non-linearity hypothesis and supports MIR spectroscopy as a realistic, low-cost basis for routine welfare monitoring.

Mid-infrared spectroscopy for large-scale monitoring of urine traits in dairy cows

S. Magro[1], G. Niero[1], A. Guerra[2], M. De Marchi[1]
[1] University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment, Viale dell'Università 16, 35020 Legnaro (PD), Italy, [2] Associazione Regionale Allevatori del Veneto, Viale Leonardo Da Vinci 52, 36100 Vicenza, Italy

Cow urine is an informative biological matrix that can be collected using non-invasive methods when sampled as spot urine. Urinary composition is used to monitor animal health, metabolic status, and renal function. Beyond disease detection, urinary traits serve as indicators for optimizing nutritional efficiency and nitrogen use in livestock, while also acting as biomarkers for heat stress and physiological adaptation in dairy cows. Urine analyses performed through standard reference methods tend to be time-consuming, expensive, and typically limited to single traits. In this context, infrared spectroscopy may offer a cost effective and rapid tool for predicting urine composition. This study aimed to assess the feasibility of using urine mid-infrared (MIR) spectra to predict urine traits. For this purpose, spot urine samples were collected from 1,271 Holstein cows in different lactation stages and parities reared in 17 farms in the northern Italy. Urine samples were analysed using the reference methods to determine pH, specific gravity, and concentrations of total nitrogen, urea, protein, creatinine, allantoin, and uric acid. Urine samples were scanned using a MilkoScan™ 7 RM (Foss Electric A/S, Hillerød, Denmark) for MIR spectra collection. Urine spectra were matched with measured urine traits and a partial least squares analysis was performed. The model was fine-tuned using 10-fold cross-validation; spectral data points were centred and scaled. The number of latent variables was set automatically but limited at a maximum of 15 to avoid overfitting. The data set was randomly split into a calibration set (including 75% of the samples) and a validation set (including 25% of the samples), ensuring similar means and standard deviations across both the sets. The highest predictive accuracy in external validation was achieved for urea ($R^2 = 0.99$) and specific gravity ($R^2 = 0.95$), while urinary nitrogen was predicted with slightly lower accuracy ($R^2 = 0.91$). Moderate performances were observed for pH ($R^2 = 0.67$), creatinine ($R^2 = 0.65$), and allantoin ($R^2 = 0.57$), whereas uric acid, protein, and protein-to-creatinine ratio were poorly predicted. Results of the present study demonstrate that urine MIR spectroscopy accurately predicts urea concentration and specific gravity, while providing useful screenings for total nitrogen and comparing group for pH, creatinine, and allantoin. The MIR instrument used in this study is routinely applied for milk analysis, including chemical composition assessment and spectral acquisition. Although urine differs in chemical composition from milk, it is also a liquid biological matrix and can be analysed using MIR spectroscopy, provided that appropriate calibration models are developed. Since this equipment is already fully integrated into the dairy supply chain, the technology could likely be adapted to urine analysis with relative ease within the existing infrastructure. Considering that spot urine samples can be easily collected by farmers or technicians, and that the predictive models developed here provide a rapid, non-invasive, and cost-effective approach, these results highlight the potential for a scalable solution to monitor urinary traits in dairy cows. This study received support from the project Cool-Cow 2023 of the Breeders Association of Veneto Region (ARAV, Vicenza, Italy).

Prediction of Dry Matter Intake Based on Milk Mid-Infrared Spectra in Holstein Cattle

C. Machefert[1], S. J. Burn[2], D. Tulpan[1], A. Fleming[3], F. Schenkel[1], C. Baes[1], F. Miglior[1,3]
[1] Centre for Genetic Improvement of Livestock, University of Guelph, Department of Animal Biosciences, 50 Stone Road E, N1G 2W1 Guelph, Canada, [2] Institute of Livestock Sciences, BOKU University, Department of Agricultural Sciences, Gregor-Mendel-Straße 33, 1180 Vienna, Austria, [3] Lactanet Canada, , N1K 1E5 Guelph, Canada

Dry matter intake (DMI) is the key component for evaluating feed efficiency of dairy cows, yet on-farm measurement is costly and requires specialized equipment. Milk mid-infrared spectra (MIRS), routinely collected for milk testing, have been used to predict major milk components and, more recently, traits such as methane production and DMI. The objectives of this study were to develop and apply prediction equations for DMI in Canadian Holstein cows based on MIRS or milk production traits. The development dataset included 21,688 records from 1,526 first-lactation Holstein cows in three herds, with DMI, milk MIRS, milk yield, and milk composition recorded from 2018 to 2025. Daily DMI (kg/d) was averaged over seven days and analyzed for two lactation periods: 5-60 (DMI60) and 61-305 (DMI305) days in milk. Partial least squares regression (PLSR) models were built using either milk processed MIRS (512 wavenumbers) or milk production traits (milk, fat and protein yields) as predictors. Models were trained and validated using 10-fold cross-validation on 80% of the data and externally validated on 20% of the data, with the split repeated 10 times. The resulting prediction equations were then applied nationally to test-day milk records from 2018 to 2025 (5,555,183 records from 1,166,510 first-lactation Holstein cows in 6,813 herds not including the 3 herds used for model construction). In the development dataset, observed and predicted DMI had identical means (17.7 kg/d for DMI60 and 21.9 kg/d for DMI305), but predicted values showed reduced dispersion (SD 2.2 to 2.8 kg/d) relative to measured DMI (SD 4.0 to 4.2 kg/d). Using MIRS as predictors yielded external-validation correlations (r) of 0.68 ± 0.02 for DMI60 and 0.60 ± 0.01 for DMI305. Models based on milk production traits showed lower predictive performance for both traits (r = 0.53 ± 0.03 and 0.57 ± 0.02, respectively). MIRS-based predictions had an external-validation mean absolute error of 2.20 ± 0.08 kg/d for DMI60 and 2.56 ± 0.08 kg/d for DMI305, whereas milk production-based models had higher errors (2.63 ± 0.07 and 2.57 ± 0.11 kg/d, respectively). In addition, DMI predicted from MIRS and from milk production traits were moderately correlated (r = 0.51 for DMI60 and 0.63 for DMI305). At the national scale, MIRS-based predicted DMI differed by about ±1-2 kg/d from the development dataset means (18.7 ± 3.3 kg/d for DMI60; 20.3 ± 2.9 kg/d for DMI305), whereas milk production-based predictions differed less from the mean. Weak correlations (<0.20) between DMI predicted by MIRS or milk production traits at the national level indicated that these proxies were not interchangeable across all different Canadian conditions. In summary, routinely-collected MIRS supported reasonably accurate DMI prediction, particularly in early lactation, and outperformed models based solely on the major milk production traits. This approach provided DMI proxies for millions of test-day records. Further work will compare sire evaluations for predicted DMI with official breeding values based on measured DMI to assess the relevance of these proxies for genetic applications. The large-scale availability of predicted DMI also created new opportunities to investigate environmental influences on feed intake, including heat stress effects.

Decoding lipolysis through individual free fatty FT-MIR model: Enhancing predictive accuracy through real-sample enrichment and advanced algorithms

O. Christophe[1], D. Vesselko[3], J. Leblois[2], F. Dehareng[1], H. Soyeurt[4]
[1] Walloon agricultural research center, Chaussée de namur 24, 5030 Gembloux, Belgium, [2] Awé group, Champs Elysées 4, 5590 Ciney, Belgium, [3] Comité du lait, Route de Herve, 104, 4651 Battice, Belgium, [4] TERRA Teaching and Research Center, Gembloux Agro-Bio Tech, Pass. des Déportés 2, 5030 Gembloux, Belgium

Lipolysis is a longstanding and topic of interest within the dairy industry. Having been extensively researched throughout the twentieth century, lipolysis is often prematurely dismissed as a settled or outdated field of study. In recent years, the advent of robotic milking systems and their related increase of milking frequencies have led to a rise in lipolysis levels, sparking renewed interest in monitoring milk quality. For individual cows, this monitoring could help to select cows who could resist to lipolysis and/or highlight bad farming practices. Predicting lipolysis more effectively relies on the analysis of free fatty acid (FFA) concentrations. Recent research has demonstrated the feasibility of quantifying individual free fatty acids in milk; specifically, the use of Fourier Transform mid-infrared (FT-MIR) spectroscopy on milk has shown promising results in predicting these traits. But this research has several limitations such as the use of unofficial reference analysis and the use of artificial lipolysis samples to gain in variability. To overcome these limitations, individual FFA models developed previously have been used to select, through the Walloon milk recording, 165 samples with a predicted high lipolysis level. Moreover, 41 samples were collected at the local farm of the CRA-W. All samples have been analyzed using the official reference analysis. FFA FT-MIR models built using Partial Least squares (PLS) regression and only the new dataset give the same performance than the literature. To improve the prediction performances as non-linear relationships can exist, advanced machine learning algorithms were tested using the full dataset (N=1004). PLS regression, Kernel Ridge Regression (KRR), Gaussian process regression (GPR) and Support vector machine Regression (SVR) give better performance than other literature models with R^2CV of 0.72, 0.5 and 0.45 for Short Chain FFA, Mid Chain FFA and Long chain FFA respectively. Adding real lipolysis samples lead to a more robust models without changing the performances. This refinement of lipolysis has resulted in improved oversight of agricultural practices and enhanced valorization of milk for the purpose of its transformation.

Using Fourier Transform Infrared (FTIR) Spectra to Investigate GXE Interactions in Danish Holstein Cattle

A. Ö. Şen[2], E. Karaman[1], A. J. Buitenhuis[1]
[1] Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Alle 3, Aarhus C, 8000 Aarhus, Denmark, [2] Ankara University, Animal Science, Ziraat Mah., Şehit Ömer Halisdemir Bulvarı, Altındağ, 06110 Ankara, Turkey

Genotype-environment interaction (G×E) plays a significant role in milk production systems because animals can respond differently to changing climatic conditions. In dairy cattle, it is often observed that current practices overlook this aspect, assuming that the same genotype will be effective across all environments. However, G×E interactions can often be a significant source of variability in productivity and reproductive performance. Understanding G×E interactions is important, especially for changing dairy cattle breeding practices. In recent years, Fourier-transform infrared (FTIR) spectra have begun to provide a new perspective not only for routine analysis of milk composition but also for the analysis of complex phenotypes with low predictability, such as disease incidence, by integrating genomic data with high-throughput phenomic information. This can serve as an indirect indicator to characterize the environmental variation that animals are exposed to. The aim of this study is to evaluate the integration of FTIR spectral data into genomic prediction models and to examine its impact on prediction accuracy across herds, considering potential genotype-environment interactions. Mastitis was used as a model trait to evaluate this approach. The dataset includes test day records (39 000) for milk yield (MY), clinical mastitis cases, and somatic cell count of 10 000 Holstein animals as well as infrared spectral data in the period of October 2023 to December 2024. Spectral data were obtained using MilkoScan FT2 (FOSS Analytical A/S), which captures infrared absorbance in the range of 5008 to 925 cm□¹, encompassing a total of 1060 individual wavelengths. Genotypes (50K SNP chip) and pedigree data were available for all animals. In this study, environmental information was extracted from phenotypic and spectral data. This study employed a kernel-based genomic prediction approach integrating milk FTIR spectral data. Preliminary findings for SCC showed a heritability of 0.08 (SE 0.02) when including a GRM only in the model. The variance explained by the IRM for SCC was 0.63, indicating that the infra-red spectra can explain some of the variance of SCC. Including both the GRM and IRM in the model showed that the GRM took most of the variance while the IRM variance went to zero. Further analyses are ongoing to evaluate model performance and investigate the possibility to use milk infrared spectra data in relation to the prediction of genotype-environment interaction.

Comparing spectral acquisition methods using a handheld NIR spectrometer for estimating legume content from legume–grass mixtures in Northern Sweden

G. Mantovani[1,2], P. Fant[1], M. Vadronova[1,3], D. Parsons[4], F. Righi[2], J. Oliveira[4]
[1] Swedish University of Agricultural Sciences, Department of Applied Animal Science and Welfare, Skogsmarksgränd, 901 83 Umeå, Sweden, [2] University of Parma, Department of Veterinary Sciences, Strada del Taglio, 43 126 Parma, Italy, [3] Czech University of Life Sciences, Department of Microbiology, Nutrition and Dietetics, Kamýcká, 165 00 Prague, Czech Republic, [4] Swedish University of Agricultural Sciences, Department of Crop Production Ecology, Skogsmarksgränd, 901 83 Umeå, Sweden

A proper legume content in pastures is essential for meeting livestock nutritional requirements and promoting sustainable pasture. The legume proportion in legume-grass mixtures can be rapidly assessed using near-infrared (NIR) spectroscopy. However, NIR predictive performance is highly sensitive to the spectral acquisition method. Previous studies have investigated the use of handheld NIR spectrometers, focusing on various scanning techniques for forage materials in dried samples. On the other hand, literature on using hand-held NIR spectrometer for estimating botanical composition from fresh pasture samples is limited, with few studies directly comparing different spectral acquisition techniques. The aim of this study was to compare two spectral acquisition methods – stationary (ST) and sliding (SL) – using a handheld NIR spectrometer for estimating legume content in fresh legume-grass mixtures in Northern Sweden. A total of 112 forage samples was collected from 12 pasture fields located in Umeå, Västerbotten County (Sweden). Fields were sown with a seed mixture of a 40% timothy (Phleum pratense L.), 40% meadow fescue (Festuca pratensis), 10% Kentucky bluegrass (Poa pratensis) and 10% white clover (Trifolium repens). Sampling was performed on three occasions from six random points on each field, using a 50 x 50 cm quadrat. The plant material within each quadrat was cut at 3.0 cm height, and the samples were manually sorted to exclude weeds and dead material. Spectral data were collected with a NeoSpectra spectrometer in the 1350-2500 nm range, using both ST and SL scanning methods. For the ST spectra collection method, the spectrometer was placed at four randomly selected points on the sample container, while for the SL technique, the spectrometer was moved over the sample surface while maintaining close contact with the forage. After scanning, each sample was manually sorted into grass and legume, and spectra from synthetic samples with 100% clover were collected (n=26). Samples were then oven-dried at 105°C for 48 hour and weighed to determine the percentage for each botanical category. The averaged spectra for each sample (138 in total), from both scanning techniques, were used to develop predictive models for legume proportion determination using partial least squares (PLS) regression. Model predictive ability was evaluated using the coefficient of determination (R^2), root mean square error (RMSE), and residual prediction deviation (RPD). The SL technique showed decreasing absorbance with increasing clover proportion, whereas ST spectra were more similar across grass proportions, suggesting improved discrimination with SL. This was confirmed by the PLS results: the SL achieved higher predictive accuracy (R^2=0.84, RMSE=11.07, and RPD=2.83) than the ST method (R^2=0.79, RMSE=17.02, and RPD=2.19). In conclusion, although both acquisition methods provided satisfactory predictions of legume proportion, the sliding technique showed a superior discriminative ability and better predictive performance in estimating legume proportion in fresh pasture samples.

BROMEDIR: Development and evaluation of a miniaturized FT-MIR instrument for in-farm milk analysis

C. Grelet[1], J. Fernández Pierna[1], Q. Arnould[1], D. Delhotte[1], M. Erfan[2], S. Labib[3], A. Kishka[3], E. Magdy[3], F. Essam[3], B. Mortada[3], Y. Sabry[3], P. Cousin[4], C. Bromedir[5], V. Baeten[1], F. Dehareng[1]

[1] Walloon Agricultural Research Center, 24 chaussée de Namur, 1435 Gembloux, Belgium, [2] Si-Ware Systems SAS, 16 rue Portalis, 75008 Paris, France, [3] Si-Ware Systems, 3 Khalid Ibn Al-Waleed St., 11361 Heliopolis, Cairo, Egypt, [4] Senseen, Traverse des Brucs, 06560 Valbonne, France, [5] Cyric, 10, Spyrou Kyprianou, 2643 Nicosia, Cyprus

Mid Infrared (MIR) analysis of milk is a powerful technology to predict a wide range of phenotypes related to fine milk composition, cow health, nutrition and environmental footprint. MIR analysis of individual cow milk samples is used by many milk recording organizations around the world for cow management. However, milk recording is classically organized every 4 to 6 weeks in farms, while to enhance the capacity of MIR analysis to be used for precision livestock farming (e.g. for early detection of diseases), the frequency of analysis should be increased. A potential solution to achieve such high frequency measurements is to bring the MIR spectrometer directly to the farm to enable daily analyses. The BROMEDIR project aims to fill this gap by developing a portable miniaturized spectrometer operating in a very wide spectral range (5000-1000 cm^{-1}), dedicated among other applications to milk analysis. Thanks to the recent technological miniaturization advances, a prototype was developed to meet dairy stakeholders' requirements and affordable cost. The objective of this work is to develop and assess the performance of the miniaturized portable MIR spectrometer in milk application. The instrument is evaluated, among other criteria, based on the general spectral pattern, the practical signal to noise ratio, the repeatability and reproducibility over time of both the spectral response and the main milk components. First results reveal a spectral profile comparable to that obtained with benchtop instruments, with identical peak assignments. Although the signal-to-noise ratio in the fingerprint region is lower than that of benchtop systems, the prototype exhibits a higher signal-to-noise ratio in the lipid-associated peak regions. The accuracy of the spectrometer to predict the main milk components is evaluated against benchtop predictions after the analysis of 50 raw milk samples from individual cows. The linearity of the peaks at 2927 and 1550 cm^{-1} with fat and protein contents, respectively, is demonstrated by coefficients of determination exceeding 0.9. Finally, the possibility to transfer existing MIR models is assessed through standardization of the BROMEDIR spectrometer against benchtop instruments. This approach would open great potential by enabling the use of past developments within the FT-MIR milk analysis framework (e.g. milk fatty acid profile and health of cows, among other).

Towards a single-step genomic evaluation of cheese-making traits predicted from MIR spectra in eight French dairy cattle breeds

A. Maupome[1], D. Duclos[2], M. Gelé[2], O. Bulot[3], A. Baur[4], N. Gaudillère[4], V. Wolf[5], D. Boichard[1], S. Fritz[1,4], M. P. Sanchez[1]

[1] Université Paris Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy en Josas, France, [2] IDELE, 149 rue de Bercy, 75012 Paris, France, [3] BGS, 149 rue de Bercy, 75012 Paris, France, [4] Eliance, 149 rue de Bercy, 75012 Paris, France, [5] Conseil d'elevage 25-90, 6 RUE DES EPICEAS, 25640 Roulans, France

The FROM'MIR project (2015–2019) developed equations predicting cheese-making properties (CMP) from mid-infrared (MIR) spectra in the Montbéliarde breed, enabling the first genomic evaluation for these traits. The APIS-GENE–funded FROM4ALL project extends these predictive models and genomic tools to eight additional French dairy breeds (Abondance, Jersey, Brown Swiss, Tarentaise, Simmental, Normande, Vosgienne, and Holstein). Six CMP were predicted from MIR spectra: fresh curd yield (CYfresh), curd yield in dry matter (CYDM), ratio of curd firming time to coagulation time for soft cheese (K10/RTCSC), curd firmness at RCT for soft cheese (aSC), curd firmness at RCT for pressed cooked cheese (aPCC), and curd firmness at 2×RCT for soft cheese (a2SC). The objectives of this study were to estimate genetic parameters for these traits and to implement single-step genomic evaluations. After quality control, the dataset comprised more than 50 million test-day records across the eight breeds. For genetic parameter estimation, 15,548,851 records from 1,950,417 primiparous cows in 27,485 herds were retained, with a minimum of three test-day records per cow. Genetic parameters were estimated using a repeatability animal model implemented in Wombat. Heritability estimates were low to moderate and consistent across breeds, aligning with previous results in Montbéliarde. Estimates ranged from 0.14 to 0.63 for cheese yields and from 0.28 to 0.49 for coagulation traits. Genetic correlations displayed clear and biologically coherent patterns: coagulation traits were strongly positively correlated (0.90–1.00), except for K10/RTCSC. As expected, faster coagulation (lower K10/RTCSC) was associated with firmer curd (aSC, a2SC, aPCC). K10/RTCSC was negatively correlated with all traits (−0.62 to −0.86) indicating that faster coagulation improves curd firmness and fresh/dry matter yields. Correlations between CMP and milk production or udder health traits ranged from low to high. CMP exhibited moderate negative correlations with milk yield but generally strong positive correlations with milk protein and fat contents. Associations with somatic cell count were weak and occasionally inconsistent across breeds. Leveraging pedigree, phenotypic, and genotypic data, we implemented a single-step genomic evaluation using a test-day model considering the first three lactations. Depending on the breed, single-step estimated breeding values (ssEBVs) were calculated using 15,340 to 18,512,229 observations from 2,234 to 2,568,184 cows, including 1,684 to 321,895 cows with genotypes. Genetic trends of CMP traits were assessed by calculating the mean ssEBVs of bulls and cows by year of birth. They generally showed improvement or stabilization across breeds and sexes, consistently with the breeding goals aiming at increasing milk protein and fat contents. Overall, our results demonstrate that all CMP are heritable and provide a prototype of single-step genomic evaluation that can be directly implemented in routine in eight dairy cattle breeds.

From routine reference data to scalable phenotypes: multivariate models combining milk MIR spectra and cow information for metabolic monitoring

A. Mensching[1], T. Gärtner[2], J. Braunleder[1], G. Witzel[3], K. Donat[2,4]
[1] IT Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany, [2] Thuringian Animal Disease Fund, Victor-Goerttler-Str. 4, 07745 Jena, Germany, [3] Qnetics, Artur-Becker-Str. 100, 07745 Jena, Germany, [4] Justus Liebig University Giessen, Veterinary Clinic for Reproductive Medicine and Neonatology, Frankfurter Str. 106, 35392 Giessen, Germany

Milk mid-infrared (MIR) spectrometry is routinely used in milk recording and enables high-throughput phenotyping. However, often prediction models for novel traits are based on limited experimental datasets and lack validation under field conditions. In the MeMoMIR project, two independently collected routine data streams—milk performance data from Qnetics, including cow information, performance traits and MIR spectra, and large-scale metabolic monitoring data from the Thuringian Animal Disease Fund—were linked to establish prediction models under practical conditions. The dataset (2020–2025) comprised 159 herds and ~17,000 cows, of which records from 119 herds and ~4,200 lactating Holstein cows (≤150 DIM) with close temporal alignment between milk and reference sampling were retained. Multivariate prediction models were developed for 23 metabolic traits using partial least squares regression, including cow-level covariates and MIR spectra. The models were extensively tuned via grid search across spectral pre-processing and model configurations. Model performance was evaluated using a strict temporal split (train: 2020–2024; test: 2025) combined with a herd-disjoint validation design to mimic prospective application under field conditions and to ensure robust assessment across heterogeneous herd environments. Predictive ability varied widely across metabolites, with R^2val ranging from 0.00 to 0.70 and a clear contrast between trait groups. The highest performance was achieved for blood cholesterol (R^2val = 0.70), followed by bilirubin (0.41), total protein (0.27) and albumin (0.26), while urea (0.23) and β-hydroxybutyrate (0.23) showed moderate predictive ability. In total, six traits reached R^2val ≥ 0.20, whereas the majority of traits showed limited predictive performance (R^2val < 0.20), indicating marked variability in predictability across metabolites and biological functions. Prediction of urine metabolites was consistently weaker than for blood-based traits, with only creatinine (0.19) and sodium (0.13) reaching R^2val values above 0.10, while several parameters such as urinary calcium (0.00) and chloride (0.00) as well as blood creatine kinase (0.00) showed negligible predictive ability. Notably, some traits (e.g. bilirubin) showed comparable or slightly higher performance in external validation than in cross-validation, indicating robust generalization under the applied validation scheme despite heterogeneous and non-experimental field data. Predictive performance may be constrained by limited biological variability, as routine monitoring predominantly includes clinically unaffected animals and thus underrepresents extreme metabolic states. These results demonstrate that MIR-based prediction under real-world conditions is feasible for selected metabolic traits in blood, while performance remains strongly trait-dependent and limited for many other analytes. The integration of previously independent routine data streams provides a unique and scalable framework for continuous model evaluation and improvement under field conditions, thereby defining both the potential and current boundaries of metabolic phenotyping from routine data. Further model refinement and targeted inclusion of animals with more diverse metabolic states are ongoing.

The efficacy of kenaf leaf meal on the apparent nutrient digestibility and physiological parameters of New Zealand white rabbit bucks

T. C. Kujoana[1], M. Mabelebele[1], W. J. Weeks[2], N. A. Sebola[1]
[1] University of South Africa, Agriculture and Animal Health, 28 Pioneer Ave, Florida Park, Roodepoort,, 1709 Johannesburg, South Africa, [2] North West Agricultural Development Institute, Agricultural Research Services, Chris Hani St, Potchefstroom Rural 2, 2520 Potchefstroom, South Africa

Abstract The current study aimed to evaluate the effects of varying levels of kenaf leaf meal (KLM) on apparent nutrient digestibility, growth performance, and haem-biochemical indices in New Zealand White Rabbit bucks (NZWRB). The authors hypothesised that varying levels of KLM have no significant effect on apparent nutrient digestibility, growth performance and haem-biochemical indices of NZWRB. Mature kenaf leaves were harvested, air-dried, and milled to produce KLM. The KLM was chemically characterised and further used to produce four KLM-based experimental diets by partially replacing soyabean meal (SMB) in rabbit grower diet: KLM0% – rabbit grower diet without KLM as substitute, KLM2.5% – rabbits grower diet with 2.5% KLM as substitute, KLM5.0% – rabbit grower diet with 5.0% as a substitute and KLM7.5% – rabbit grower diet with 7.5% as a substitute. Twenty-eight (28) NZWRB at fourteen weeks of age with an initial weight of 2.3 ± 0.47 kg, were randomly allocated to four experimental diets (KLM0%, KLM2.5%, KLM5.0% and KLM7.5%) in a complete randomised design (CRD) for a period of 70 days. The experimental unit was a pen (0.07 m2 per buck) housing one NZWRB buck, replicated seven (7) times. The collected data on apparent nutrient digestibility, growth performance, and haem-biochemical parameters were statistically analysed using SAS, version 9.2.1 (2010). The means were separated using Duncan's multiple range test, and significance was considered at $p < 0.05$. The results showed that rabbits fed KLM5.0 and KLM7.5% had the highest ($p < 0.05$) crude protein, lysine, aspartic acid, glutamine and copper digestibility, while those fed KLM2.5% had the highest ($p < 0.05$) leucine digestibility. Rabbits fed KLM7.5% had the highest ($p < 0.05$) weight gain at week 6, while those fed KLM2.5, KLM5.0, and KLM7.5% had the highest weight gain at week 10. Haemoglobin was highest in rabbits fed KLM2.5 and KLM5%, while red blood cell count was highest ($p < 0.05$) in rabbits fed KLM5.0%. Rabbits fed KLM2.5 and KLM5.0% highest white blood cell count, while those fed KLM7.5% had the highest ($p < 0.05$) blood phenolics and antioxidants. Blood potassium and aspartate transferase were highest ($p < 0.05$) in rabbits fed KLM2.5 and KLM5.0%, while rabbit bucks fed KLM5.0% had the highest ($p < 0.05$) creatine kinase. Rabbits fed KLM5.0 and KLM7.5% had the highest ($p < 0.05$) blood glucose and iron. The KLM5.0 and KLM7.5% showed improved nutrient digestibility and growth performance, indicating that KLM can be a valuable feed ingredient for rabbits. Therefore, it can be gradually incorporated into the rabbit diet up to 7.5% without negatively impacting the overall growth and health performance. Keywords: Growth performance, kenaf leaf meal, soyabean meal, nutrient digestibility, haem-biochemical indices, health performance.

Performance of rabbit does fed a lactation diet based primarily on agro-food by-products: implications for a circular economy

Z. Volek[1], L. Zita[2], P. Šufliarský[1], L. Pohlová[1]
[1] Institute of Animal Science, Department of Nutritional Physiology and Animal Product Quality, Přátelství 815, 10400 Prague-Uhříněves, Czech Republic, [2] Czech University of Life Sciences Prague, Department of Animal Science, Kamýcká 129, 16500 Prague-Suchdol, Czech Republic

Within the framework of a circular bioeconomy, population growth and increasing resource constraints are expected to shift livestock production, including rabbit meat production, toward circular models that prioritise locally available protein sources and agro-industrial by-products. Rabbit nutrition may serve as a suitable model for this approach. This study compared a conventional lactation diet (CL diet; alfalfa meal, soybean meal, wheat bran, sugar beet pulp, oats, barley, and rapeseed oil) with a lactation diet based primarily on agro-food by-products (L-AFB diet; rapeseed cake, wheat bran, sugar beet pulp, maize bran and flour, buckwheat hulls, and sunflower hulls), with alfalfa meal, soybean meal, oats, barley, rapeseed oil, and supplemental dicalcium phosphate completely excluded. The diets were comparable in crude protein, fibre fractions, limiting amino acids, calcium, and phosphorus. The L-AFB diet contained slightly more ether extract and less starch and digestible protein than the CL diet. Both diets were isoenergetic. A total of 32 rabbit does (16 per treatment; 4th parturition) were fed one of the two diets throughout the 32-day lactation period. Does were housed in modified cages allowing controlled suckling and separate access to feed for does and their litters. Litters were standardised to 10 kits at birth and received their mothers' lactation diets from day 17. Milk composition was analysed in five does per treatment. Dietary treatments did not affect doe live weight at the end of lactation (on average 4795 g), average daily feed intake (on average 434 g), average daily milk production (on average 274 g), or milk, fat, and protein output (on average 77.7, 9.3, and 7.3 g/d/kg metabolic weight, respectively). Litter live weight at 32 days (weaning) was also unaffected by the dietary treatments (on average 6945 g). Between days 22 and 32 of lactation, litters from does fed the L-AFB diet consumed slightly less solid feed (by 2.8 g/d; $P = 0.020$) and had a higher milk-to-solid feed intake ratio (by 0.26; $P = 0.016$). These results support the idea that diets based primarily on agro-food by-products can represent a viable alternative feeding strategy for rabbit does, providing an environmentally friendly approach to rabbit meat production. The study was supported by a project NAZV QL 24010136.

Dietary evaluation of Pleurotus ostreatus spent mushroom substrate as a sustainable feed ingredient for enhancing performance, egg oxidative stability and ovarian homeostasis in laying hens

I. Brouklogiannis[1], G. Koutrotsios[2], I. Poulopoulou[1], G. I. Zervakis[2], K. C. Mountzouris[1]
[1] Agricultural University of Athens, Animal Science, Iera Odos 75, 11855 Athens, Greece, [2] Agricultural University of Athens, Crop Science, Iera Odos 75, 11855 Athens, Greece

The valorization of agro-industrial by-products in poultry nutrition aligns with circular bioeconomy principles and sustainable production strategies. This study evaluated the dietary inclusion of Pleurotus ostreatus spent mushroom substrate (SMS) on laying performance, nutrient digestibility and egg quality. Additionally, key ovarian homeostasis-related genes involved in detoxification (aryl hydrocarbon receptor-AhR), antioxidant (nuclear factor erythroid 2–related factor 2-Nrf2), and inflammatory response (nuclear factor kappa B-NF-κB) were assessed. A total of 196 Hy-Line Brown laying hens (51 weeks of age) were allocated to 4 dietary treatments with 7 replicates of 7 hens each, receiving isocaloric, isonitrogenous and isofibrous diets containing 0 (S0), 25 (S25), 50 (S50), or 100 (S100) g SMS/kg diet for 7 weeks. Productive performance was recorded daily and was reported for the overall period, while total tract apparent nutrient digestibility was determined at week 7. At the end of the trial (week 7), eggs were collected to assess quality and oxidative stability in fresh and stored conditions, and ovarian samples were obtained for qPCR analysis. Data were analyzed using ANOVA with means compared by Tukey's honest significant difference test. Polynomial contrasts tested the linear and quadratic effects of SMS inclusion levels. Increasing SMS inclusion improved laying rate and egg mass ($P \leq 0.05$), with the highest responses observed in S100 compared with the control treatment (S0). Ether extract digestibility was enhanced ($P = 0.002$) in all SMS-supplemented treatments compared with S0. Egg oxidative stability was improved ($P \leq 0.001$), as reflected by reduced yolk malondialdehyde and egg-white protein carbonyl concentrations in fresh and stored eggs, particularly in S100. The nutrigenomic analyses revealed that SMS inclusion downregulated most of the AhR (3/4) and NF-κB (8/13) pathway genes assessed, mainly in S50 and S100 treatments. In addition, SMS-related cytoprotective potential was demonstrated via beneficial changes seen for the majority (5/9) of the Nrf2 pathway genes assessed, with S100 displaying the most significant differences from S0. In conclusion, dietary SMS inclusion at 100 g/kg improved layer productivity, ether extract digestibility and egg oxidative stability. These responses were mechanistically supported by beneficial modulation of ovarian cytoprotective and inflammatory responses. Overall, these findings support the use of SMS as a sustainable functional feed ingredient to enhance poultry productivity, egg quality and physiological resilience.

Impact of Moringa oleifera leaf meal supplementation on the growth, nutrient digestibility, and meat quality of quails fed sorghum-canola-based diets

N. A. Sebola[1], T. C. Kujoana[1], H. K. Mokoboki[2], F. Manyeula[1], M. Mabelebele[1]
[1] University of South Africa, Agriculture and Animal Health, 28 Pioneer Ave, Florida Park, 1709 Roodepoort, South Africa, [2] North-West University, Animal Science, P /Bag x2046, Mmabatho, 2735 Mafikeng, South Africa

Abstract Sorghum and canola meal are low in xanthophyll and carotenes which are responsible for egg pigmentation. It is, therefore, imperative that alternative and sustainable way of incorporating a safer and local phytogenic plant should be implemented to avoid white yolk which could lead to eggs being rejected by the consumer in the market. No research has been conducted world-wide on the feeding quail's sorghum-canola based diets supplemented with Moringa oleifera leaves meal (MOLM) in South Africa. The aim of the study was to investigate the effects of feeding Japanese quail's sorghum-canola based diets supplemented with MOLM as a feed additive on nutrient digestibility, growth performance, egg production, carcass characteristics and meat quality. A total of 140 Japanese quails (42.7 ± 4.81g of live weight) were reared on 5 iso-caloric and iso-nitrogenous diets formulated by using maize + soybean and white sorghum + canola meal supplemented with MOLM. The study was separated into two experiments: 1A – quails raised on diets without MOLM supplementation from week 4-8 and 1B quails raised on diets with MOLM supplementation from week 9-12. Growth performance and nutrient digestibility and egg production were measured for 5 weeks. Thereafter, the quails were humane slaughtered for carcass traits and meat quality. The collected data were statistically analysed using SAS, version 9.2.1. The means were separated using Duncans's multiple range test, and significance was considered at $p < 0.05$. In experiment 1A, protein efficiency ratio (PER) was the highest on quails reared on sorghum- canola based diets (SCD) in week 8. In experiment 1B, with MOML supplementation, crude protein digestibility was the highest in quails reared maize-soyabean based diets supplemented with 25% (MBD25), while overall weight gain and egg production was the highest on quails reared on maize-soybean based diets supplemented with 50% (MBD50) MOLM. Protein consumed was lower ($p < 0.05$) on quail reared on maize-soybean based diets supplemented with 50% MOLM while PER was the highest on sorghum-canola based diets (SCD) supplemented with 50% MOLM. Quails fed CM50 had the shorter ($p < 0.05$) small intestine compared to those fed other treatment diets. Meat b* was significantly lowest from quails fed maize soybean-based diets supplemented with 25% MOLM. Meat pH24 was lowest ($p<0.05$) from quail fed MBD50. Based on nutrient digestibility, weight gain and egg production, it can be concluded that maize soybean-based diet supplemented with 50% MOLM does not result in adverse effects on diet utilisation, growth performance and meat quality of quails. Anti- nutritional factors in sorghum canola-based diets need to be ameliorated before being used as energy sources. Keywords: Quails, nutrient digestibility, growth performance, egg, meat, canola meal, Moringa oleifera leave meal

Environmental Sustainability and Functional Performance of Alternative Feed Ingredients: An Evidence Synthesis

R. Juel[1,2], M. Hegwood[1], A. Khimasia[1]
[1] The Centre for Feed Innovation, 71-75 Shelton Street, WC2H 9JQ London, United Kingdom, [2] Sapienza - Università di Roma, Piazzale Aldo Moro 5, 00185 Rome, Italy

Background Alternative feed ingredients such as macroalgae, algal oils, single-cell proteins, and insects are increasingly proposed as sustainable alternatives to conventional feed ingredients. However, environmental impacts vary widely depending on production systems and feedstocks used, energy sources, and processing pathways. Circular production approaches, such as using by-products, residual streams, and wastes as inputs and valorising co-products, have therefore emerged as strategies to improve the sustainability of feed ingredient production. At the same time, questions remain regarding the nutritional adequacy and performance of feeds derived from these alternative ingredients. While nutritional profiles can vary depending on production processes and may be optimised through formulation, evidence linking environmental and animal nutrition outcomes remains fragmented across disciplines. In addition, methodological differences across life-cycle assessments (LCAs) and feed trials limit comparability between ingredients and their underlying production systems. The aim of this study was to compare emerging alternative feed ingredients used in livestock, aquaculture, and pet food systems in terms of their ability to support both sustainability and animal health outcomes. The objectives of this study were to: (1) evaluate the environmental sustainability of selected alternative feed ingredients across key impact domains; (2) examine how variation in production conditions, including circular production pathways, influences sustainability performance; and (3) assess whether lower-impact ingredients and production pathways are compatible with acceptable animal health and performance outcomes. Methods We conducted a structured synthesis of peer-reviewed LCAs and sustainability studies reporting greenhouse gas emissions, land use, energy use, and water use. Environmental indicators were standardized to comparable functional units and analysed across production system characteristics, including feedstock, energy source, and processing pathway. In parallel, we reviewed peer-reviewed feeding trials assessing outcomes including digestibility, palatability, gastrointestinal tolerance, and growth performance. Results Environmental outcomes varied widely across ingredients and were strongly influenced by production systems. Key drivers of environmental impacts included energy sources, feedstock, processing intensity, and co-product management. Production systems integrating renewable energy or valorising by-products generally showed more favourable environmental profiles. Evidence from nutrition studies suggests that low to moderate inclusion of alternative feed ingredients is generally well tolerated across a number of species and can, in some cases, support improved growth or health outcomes. At higher inclusion levels, results are more variable, with the common limitations relating to growth rates, palatability and gastrointestinal tolerance. Discussion/Conclusion Overall, the findings suggest that alternative feed ingredients can support both sustainability and animal health goals, but outcomes depend strongly on how ingredients are produced and used. More circular and lower-impact production pathways appear promising, particularly when paired with low to moderate inclusion levels that maintain acceptable nutritional performance. This highlights the need to assess alternative ingredients not as uniform categories, but in relation to the specific production systems and feeding strategies under which they are deployed.

Alternative legumes as a sustainable replacement for soybean meal in Iberian pig diets: effects on growth performance and plasma metabolites

A. Román[1], I. Fernández-Fígares Ibáñez[1], M. Lachica López[1], C. García Contreras[1], R. Nieto Liñán[1]
[1] Estación Experimental del Zaidín, Department of Nutrition and Sustainable Animal Production, Profesor Albareda, 1, 18008 Granada, Spain

Legume grains can be an excellent source of protein in animal diets. The scientific community is adopting strategies for the cultivation, production and use of local legumes as potential feed protein sources aiming to improve the sustainability of feed and livestock production chains, affected by production costs, market instability and long-distance transportation of feedstuffs such as cereals and soybeans, that are mainly produced in North and South America. Our aim was to evaluate local protein sources, such as peas, chickpeas and lentils, as a sustainable alternative to soya through the impact on growth performance and plasma metabolites of Iberian pigs, a relevant Spanish native pig breed. A total of thirty-two pure Iberian barrows were randomly allocated into four experimental groups: a control group fed soybean meal and three groups in which 50% of soybean protein was replaced by local legume protein (peas, cull chickpeas and cull lentils). Diets were isoproteic and isocaloric, covering animals' needs and formulated according to the ideal protein concept. Pigs were individually housed under temperature-controlled conditions (22 ± 1ºC) with access to feed and water ad libitum and weighed weekly. Initial weight was 33 ± 1.3 kg and final weight was 74 ± 2.5 kg. 10 weeks after the beginning of the trial, animals were slaughtered after 24 h fasting by electrical stunning and immediate exsanguination. Blood samples were processed to analyze biochemical parameters: albumin, β-hydroxybutyrate, HDL-cholesterol, LDL-cholesterol, total cholesterol, creatine, glucose, lactate, triglycerides and urea. Treatment effects were assessed by analysis of variance with a significance level of 0.05. No significant differences were found among treatments for average weight gain (41.4, 40.8, 40.8 and 42.5 kg, for control, chickpea, pea and lentil groups, respectively; standard error of the mean (SEM): 1.49; $P > 0.05$), average daily gain (820, 810, 810, 842 g/day, for control, chickpea, pea and lentil groups, respectively; SEM: 34.9; $P > 0.10$), average feed intake (2775, 2716, 2783, 2848 g of dry matter/day, for control, chickpea, pea and lentil groups, respectively; SEM: 100.5; $P > 0.10$) and feed efficiency (g/g) (0.296, 0.291, 0.297, 0.295, for control, chickpea, pea and lentil groups, respectively; SEM: 0.006; $P > 0.10$). Likewise, there were no differences in the plasma biochemical metabolites ($P > 0.10$), except for creatinine, which was lower in the control and lentil group, compared to chickpea and pea groups (0.60, 0.62, 0.73, 0.74, respectively; SEM: 0.04; $P < 0.05$), and a numerical trend suggesting that lentils reduced plasma triglycerides ($P = 0.065$). The present results indicate that substitution of 50% of soy protein with locally grown protein did not negatively affect growth performance or plasma biochemical parameters. These finding suggests that incorporating local legumes into pig diets could enhance the sustainability of the pig production chain without compromising animal performance. Funded by the EU project Facilitating Innovations for Resilient Livestock Farming Systems, abbreviation: Re-Livestock (reference number: 101059609).

Alternative legumes as a sustainable replacement for soybean meal in Iberian pig diets: effects on nutrient digestibility, nitrogen balance and inflammatory markers

A. Román[1], I. Fernández-Fígares Ibáñez[1], M. Lachica López[1], C. García Contreras[1], R. Nieto Liñán[1]
[1] Estación Experimental del Zaidín, Department of Nutrition and Sustainable Animal Production, Profesor Albareda, 1, 18008 Granada, Spain

Legume grains can be an excellent source of protein in animal diets. The scientific community is adopting strategies for the cultivation, production and use of local legumes as potential feed protein sources aiming to improve the sustainability of feed and livestock production chains, affected by production costs, market instability and long-distance transportation of feedstuffs such as cereals and soybean, that are mainly produced in North and South America. Our objective was to assess local protein sources –such as peas, chickpeas, and lentils- as sustainable alternatives to soybean by evaluating their effects on nutrient digestibility, nitrogen balance, and intestinal inflammation markers in Iberian pigs, an important native Spanish breed. A total of thirty-two pure Iberian barrows were randomly allocated into four experimental groups: a control group fed diets with soybean meal as the main protein source and three groups in which 50% of soybean protein was replaced by local legume protein (peas, culled chickpeas and culled lentils). Diets were isoproteic and isocaloric, covering animals' needs and formulated according to the ideal protein concept. Pigs were individually housed under temperature-controlled conditions (22 ± 1ºC) with access to feed and water ad libitum. Initial weight was 33 ± 1.3 kg and final weight was 74 ± 2.5 kg. Three weeks after the beginning of the trial, faecal digestibility and nitrogen balance were assessed in 24 animals (6 per treatment). Samples of faeces and urine were obtained quantitatively for 4 consecutive days. Excreta samples were homogenized and freeze-dried to determine dry matter, organic matter, nitrogen and energy ingested and excreted in faeces and nitrogen and energy excreted in urine. At the end of the 10-week trial, pigs were slaughtered and samples of faeces from the rectum collected for biochemical analysis of two markers of intestinal inflammation: calprotectin and myeloperoxidase. Treatment effects were assessed by analysis of variance with a significance level of 0.05. No significant differences were found between the total tract apparent digestibility coefficients for dry matter (mean value: 0.862; standard error of the mean (SEM): 0.009; $P > 0.10$), organic matter (mean value: 0.883; SEM: 0.008; $P > 0.10$), nitrogen (mean value: 0.801; SEM: 0.015; $P > 0.10$) or energy (mean value: 0.861; SEM: 0.009; $P > 0.10$). Furthermore, no differences were observed on the amount of ingested nitrogen nor retained nitrogen ($P > 0.05$). Likewise, the values for retained nitrogen/ingested nitrogen (mean value: 0.451; SEM: 0.042) and retained nitrogen/digested nitrogen (0.562; SEM: 0.049) were not significantly different between groups ($P > 0.10$). Finally, faecal calprotectin concentrations were significantly higher in the control group compared with the local-legume fed groups ($P < 0.10$). However, myeloperoxidase levels remained unaffected ($P > 0.10$). These results suggest that replacement of 50% of soy protein with protein from locally-grown legumes did not impair nutrient digestibility nor nitrogen balance and may improve gut inflammation enhancing the sustainability of pig production. Funded by the EU project Facilitating Innovations for Resilient Livestock Farming Systems, abbreviation: Re-Livestock (reference number: 101059609).

From circularity to practical application: optimizing food industry co-products for pig and poultry feeding

A. Cerisuelo[1]
[1] Instituto Valenciano de Investigaciones Agrarias, Centro de Investigación y tecnología Animal, Polígono Industrial La Esperanza, 100, 12400 Segorbe, Spain

The use of agro-industrial co-products and other food-derived ingredients in feeds for pigs and poultry has been widely recognized as a feeding strategy that contributes to circularity and reduces the environmental impact of feed production. The main reason is that these ingredients originate from other industrial processes and require fewer resources -such as land, water, or fuel- than conventional soybean meal and cereals for their production. Additionally, they are generally not suitable for human consumption and are available in local markets, thereby reducing food-feed competition and reliance on imported raw materials. These issues are particularly significant in the current demographic and geopolitical situation. For all these reasons, the incorporation of by-products derived from crop cultivation, as well as from fruit, vegetables, and other food-processing industries, into animal feeding has become a central topic in both European and global discussions. The research conducted in our laboratory for more than 15 years on agro-industrial co-products such as citrus pulp, olive cake, brewery spent grains, rapeseed and camelina meals, among others, has shown that, beyond being nutrient-rich resources, they can provide several additional advantages related to animal health, meat or egg quality, and gas emissions from slurry. Owing to their composition, which is typically rich in fibre fractions and bioactive constituents such as phenolic compounds, their inclusion in diets can positively modulate and support a favourable gut microbiota composition and functionality, activating metabolic pathways beneficial for pigs' health. In addition, co-products in feeds have the capacity to mitigate ammonia emissions from slurry, although their effects on methane emissions are more variable. However, these alternative ingredients are also widely known to present certain limitations, including issues related to availability, variability, the need for appropriate preprocessing in most cases, and constraints in nutrient availability. This latter aspect is particularly relevant for monogastric animals, as it can negatively affect nutrient digestibility and increase the overall amount of excreta, potentially reducing the environmental benefits typically attributed to the use of by-products. Factors such as the amount and type of fibre, as well as their physicochemical characteristics can contribute to this issue, and the inclusion level in the diet plays a major role in it. Addressing these issues is essential for ensuring the effective and sustainable integration of co-products into livestock diets. Extensive research is currently being conducted in the field of emerging technologies and innovative approaches to optimize their nutritional value. These innovations include treatments such as fermentation or micronutrient biofortification, as well as the use of exogenous enzymes, such as specific fibrolytic enzymes, capable of degrading both soluble and insoluble fibre. Additionally, artificial intelligence tools, including machine learning algorithms, have recently been applied to predict nutrient deficiencies and optimize diet formulation based on animal responses. With sufficient data, these models can identify optimal feedstuff combinations to maximize efficiency, helping determine suitable feeding strategies that incorporate by-products and assess their broader sustainability impacts. Future research should focus on better characterizing agro-industrial and other food industry co-products and its effects, and refining feeding strategies with these ingredients using available technological and digital tools to enable their practical adoption on farms.

Hybrid rye inclusion in fattening pig diets to reduce environmental impacts

L. Cappelaere[1], L. Eastwood[2], M. P. Létourneau-Montminy[1]
[1] Université Laval, Département des sciences animales, Pavillon Paul Comtois, rue de l'agriculture, G1V 0A6 Québec, Canada, [2] KWS Seeds Canada, 400, 909 17 Avenue SW, T2T 0A4 Calgary, Canada

Diversification of rotations is a main lever to improve sustainability of agriculture, through improved soil health, reduced used of pesticides and fertilizers, and improved yields. Fall hybrid rye is a good candidate crop to introduce in conventional rotations, with low input requirements, improved soil coverage and higher yields compared to other winter cereals. However, a main barrier to adoption is lack of market opportunities to sell these crops. Animal feed, and more precisely pig feed, could be a good market as pigs fed hybrid rye have shown good performance results, and replacing corn with rye could reduce the environmental impact of feed and pig production overall. The objectives of this study were to quantify the environmental impacts of introducing hybrid rye in a Corn-Soybean rotation in Quebec (Canada) and to evaluate the environmental impact reductions associated with replacing corn with local rye in pig feed. Life cycle assessments (LCAs) based on primary data were carried out using SimaPro® software, comparing a corn-soybean rotation and a corn-soybean-hybrid rye + legume cover crop. Impacts of hybrid rye produced in Quebec was calculated based on a harvest-to-harvest year. Impacts taking into account benefits of the rotation were calculated by allocating reduction of corn and soybean impacts to rye. Iso-net-energy and iso-digestible-lysine fattening pig diets were formulated with 25% or 50% of corn replaced by rye (S25 and S50 respectively), compared to a control that represented local practices (four feeding phases). A farm-gate LCA of these strategies was performed assuming no effect on performance and using rye LCA values calculated in this study and Tier 3 modelling of manure composition and emissions. Impacts were expressed per kg of bodyweight. The ReCiPe characterization method was used. One kg of rye had lower impacts than 1 kg of corn, except for land occupation. Climate change impact was 19% lower, freshwater ecotoxicity 13% lower and eutrophication 3% lower. Including rotation benefits decreased rye impacts by more than 30% for all impacts except ecotoxicity. When considering harvest-to-harvest rye impact values, most impacts of pig production were reduced: climate change impact was reduced by 3% for S25 and 6% for S50, eutrophication was reduced by 6% and 16% for S25 and S50, respectively, fine particle formation by 5% and 8%, ecotoxicity by 6% and 11%, fossil resource depletion by 7% and 17%, acidification by 4% for S25 and 5% for S50. Land use increased by 3% and 6% for the two replacement levels, respectively. When allocating rotation benefits, impact reductions were higher, especially for eutrophication: 36% of reduction for S25 and 77% for S50. Fossil resource depletion was reduced by 12% and 27% for S25 and S50, respectively, and climate change by 6% and 12%. Land use was reduced for S25 and S50 with these impact values of rye. Other impacts were reduced by between 6% and 8% for S25 and between 10% and 15% with S50. Adding hybrid rye to crop rotations and pig diets in Quebec is an efficient strategy to decrease environmental impacts of the sector, with no major trade-offs between impacts or to animal performance.

Meta-Analytical Prediction of Metabolizable Energy in Solvent-Extracted Canola Meal pigs Using Chemical Composition

H. Salgado[1], M. P. Létourneau-Montminy[1]
[1] Université Laval, animal sciences, 2425, rue de l'Agriculture, G1V0A6 Quebec, Canada

The shifting from fossil-derived sources to plant-based alternatives has increased the production of oilseed and, consequently, the availability of oilseed meals. In Canada, canola meal (CM) is a by-product of canola seed oil extraction and an important protein source for livestock, including swine. Optimizing the nutritional use of CM is critical for enhancing its value for canola production chain and the swine industry. However, variability in its chemical composition can influence its metabolizable energy (ME) contribution to swine diets. Therefore, the objective of this study was to predict the ME of CM for swine based on its nutrient composition using a meta-analysis approach. A dataset comprising 19 studies (56 experimental treatments) that reported ME values of solvent-extracted CM for pigs between 20 and 50 kg body weight, along with chemical composition data (crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), ether extract (EE), and ash), was compiled. This dataset was extracted from an initial collection of publications addressing nutrient and energy digestibility of canola, rapeseed, or double-zero rapeseed meals for growing pigs. Studies lacking ingredient composition data or oilseed meals with EE > 6.5 % of DM were excluded. Chemical composition variables were first evaluated for multicollinearity and then subjected to stepwise selection for inclusion in the meta-regression. The meta-regression was performed using the MIXED procedure in Minitab, with ME as the dependent variable and selected composition variables as fixed predictors, while study was considered a random effect. Model adequacy was verified using the 'studentized' residuals and residual's normality. Outliers were identified as data points with residuals outside the (-3,3) range. The average chemical composition (% of DM) of the meals was: CP = 41.8 % ± 2.6, NDF = 34.2 % ± 7.31, ADF = 21.5 % ± 5.5, EE = 2.9 % ± 1.4, and ME = 2975 ± 317 kcal/kg of DM. The first model identified NDF, EE and ash as the main predictors of ME. However, ash was excluded due to collinearity with NDF ($r = 0.279$; $P < 0.05$). The final model revealed a negative effect of NDF (-25.31 kcal / % point of NDF; $P < 0.001$) and a positive effect of EE (60.4 kcal / % point of EE; $P < 0.05$) on ME. The R^2 of the final model including the random effect of study was 87.7 %. These results confirm the negative effect of NDF on ME, which is consistent with previous findings in the literature. The model highlights NDF as a key determinant of the energy value of canola meal and provides a practical predictive tool for estimating ME from routine chemical analyses.

Dietary former food products modulate fecal microbiota and are associated with improved carcass composition in heavy pigs

M. Tretola[1], K. Poklukar[2], M. Skrlep[2], G. Bee[1], M. Candek-Potokar[2]
[1] Agroscope, Swine Research Group, Tioleyre, 4, 1725 Posieux, Switzerland, [2] Agricultural Institute of Slovenia, Hacquetova, 17, SI-1000 Ljubljana, Slovenia

Former food products (FFPs) from the food industry represent a sustainable alternative to cereals in pig nutrition. While their nutritional value has been documented, their impact on gut microbial ecology and its potential relationship with carcass traits remains unclear. This study evaluated the effects of increasing dietary inclusion of FFPs (0%, 20%, 40%) on fecal microbiota composition in heavy pigs and explored associations with performance and carcass characteristics. Thirty-six pigs were fed iso-caloric and iso-proteic diets containing 0% (Control), 20% (FFP20), or 40% (FFP40) FFPs in the diets of grower (20-60 kg BW), finisher I (60-100 kg BW) and finisher II (100-140 kg BW) pigs. Growth performance and carcass composition (dual-energy X-ray absorptiometry) were recorded. Fecal samples (n = 36) were analyzed by whole-metagenome sequencing, and the differential gene expression (DEG) analysis of jejunum mucosa was performed with RNA-sequencing. Feed efficiency improved linearly with increasing FFP inclusion (up to +9% in the finisher II period; $P < 0.001$), while carcass fat decreased (−6%; $P \leq 0.009$) and protein content increased (+3%; $P < 0.001$) compared with Control pigs. Alpha diversity indexes (Observed ASVs, Shannon, Evenness-Simpson) were not affected by diet ($P > 0.10$), indicating preserved microbial richness and evenness. However, beta diversity (Bray–Curtis) showed a tendency toward dietary clustering (Adonis $P = 0.079$), with FFP20 exhibiting the most distinct microbial profile. Linear discriminant analysis effect size (LDA > 3) identified 33 discriminant taxa. FFP20 showed the highest number of microbial markers, mainly belonging to the class Erysipelotrichia (including Turicibacteraceae and Turicibacter bilis). FFP40 was characterized by enrichment of Romboutsia (including Romboutsia timonensis) and members of Chlamydiaceae, whereas Control pigs were enriched in Bifidobacteriaceae (genus Pseudoscardovia) and Megasphaera. Core microbiota analysis (≥0.1% relative abundance; ≥80% prevalence) identified 21 shared taxa between Control and FFP20, while FFP40 exhibited a reduced core (16 taxa), suggesting dose-dependent restructuring of stable microbial populations. Also, correlation analysis revealed a strong positive association between lean meat percentage and Peptostreptococcaceae and Romboutsia timonensis, whereas belly fat positively correlated with Bifidobacteriaceae. RNA-sequencing of jejunal mucosa tissue revealed a small number of significant DEGs (adj. $P < 0.05$, $|\log_2 \text{ fold change}| > 1$). Therefore, gene set enrichment analysis was performed using ranked $\log_2$ fold change values. Comparison of the FFP40 and Control showed enrichment of gene sets associated with the cell cycle, lipid, alcohol, and sterol biosynthetic processes (adj. $P < 0.05$). Additionally, comparison of the FFP20 diet with the Control revealed enrichment of gene sets involved in lipid biosynthetic processes, regulation of the immune system and RNA processing (adj. $P < 0.05$). Direct comparison between the FFP40 and FFP20 groups further identified enrichment of cell cycle and carboxylic acid catabolic processes (adj. $P < 0.05$). In conclusion, dietary FFP inclusion modulated gut microbial community structure without affecting overall diversity and was associated with improved feed efficiency and reduced carcass fat deposition. Accordingly, the enrichment of the gene sets involved in lipid processes was identified in jejunal mucosa with inclusion of FFPs. Moderate inclusion (20%) induced the most pronounced microbial differentiation, while higher inclusion (40%) reduced core microbiota stability.

Digestibility of mycoprotein derived from Paecilomyces variotii in growing pigs

E. Ivarsson[1]
[1] Swedish University of Agricultural Sciences, Department of Applied Animal Science and Welfare, PO. 7024, 75007 Uppsala, Sweden

Mycoprotein derived from the biomass of filamentous fungi through controlled fermentation has emerged as a promising alternative feed ingredient. Filamentous fungi are well known for their ability to secrete a broad spectrum of enzymes, enabling them to degrade and assimilate a wide variety of complex substrates. Mycoprotein grown on low-value sidestreams has low land use and the potential to increase European protein production and contributing to a circular food system. In pig production, feed is the major contributor to the carbon footprint, and the use of feed-efficient pigs together with feed ingredients with a low carbon footprint, such as by-products, is often highlighted as an important strategy to reduce the environmental impact of pig production. In this study, dried milled mycoprotein from Paecilomyces variotii grown on sulfate liquor from pulp production was used to determine its total tract apparent digestibility (TTAD) of organic matter and energy, and the standardized ileal digestibility (SID) of crude protein and amino acids in pigs. The analyzed chemical composition of the P. variotii mycomeal showed a high content of crude protein (52.3% on a dry matter basis) and amino acids (35 g/kg DM lysine and 7 g/kg DM methionine), as well as a high content of crude fibre (27.5% on a DM basis). In the digestibility study, a total of 14 individually housed pigs were used and assigned to two experimental feeds: a protein-free basal feed, and a feed in which 30% of the basal feed was substituted with mycomeal from P. variotii (PV). The pigs were crosses between Yorkshire × Hampshire and weighed 34.3 ± 1.76 kg at the start of the experiment. They were fed the experimental feeds for 11 days, including seven days of adaptation, followed by three days of fecal collection. On day 11, the pigs were euthanized, and ileal digesta were collected. The digesta and feces were freeze-dried prior to analysis. Feed and digesta were analyzed for dry matter, crude protein (CP), titanium dioxide, and amino acids. In addition, feed and feces were analyzed for ash and gross energy. Digesta samples from pigs fed the protein-free basal feed were used to calculate basal endogenous losses, and the results showed values that corresponded well to previously published values (CVB, 2019). The TTAD of organic matter in PV was 65.4 ± 1.52%, and of gross energy, 63.7 ± 3.14%. The SID of CP, lysine, and methionine was 73.0 ± 2.24%, 75.6 ± 2.46%, and 72.8 ± 2.66%, respectively. These results indicate that P. variotii grown on sidestreams from the forest industry is a valuable source of protein with acceptable SID values in pigs. However, the high crude fibre content limits its TTAD of energy and organic matter, and processing methods that reduce cell wall content could improve energy utilization in pigs.

The impact of replacement imported protein sources with alternative domestic protein feeds in the feeding of fattener pigs on of their fattening, slaughter and economic value

K. Kropiwiec-Domańska[1], M. Babicz[1], M. Szyndler-Nędza[2]
[1] University of Life Sciences in Lublin, Department of Animal Breeding and Agricultural Consulting, Akademicka 13, 20-950 Lublin, Poland, [2] National Research Institute of Animal Production, Department of Pig Breeding, Krakowska 1, 32-083 Balice, Poland

The most expensive ingredient in animal feed is crude protein. Currently, the main source of protein in feed for pigs kept in the European Union countries is post-extraction soybean meal derived from genetically modified plants, imported mainly from the USA, Brazil and Argentina. About 2.5 million tons are imported to Poland every year, with the price of the component rising steadily, which negatively affects the profitability of pig production. Many European Union countries are carrying out a number of measures to reduce GMO feed, especially soy, in the feeding of farm animals. Research is underway to replace soybean-derived protein with protein from seeds of domestic legumes such as peas, lupins or faba beans. The aim of the research is to evaluate the replacement of post-extraction soybean meal with high-protein plants grown in Poland in the diet of fattener pigs in terms of their fattening and slaughter value as well as production profitability. Peas, faba beans, sunflower meal and hemp and linseed cake were the main source of protein in the experimental group. The experiment was carried out on 60 fatteners of the Puławska breed and lasted 119 days, and the average age at slaughter for both groups was 184.90 days. The body weight on the day of slaughter ranged from 105 to 128 kg (control group) and 105 to 124 kg (experimental group). The study included an assessment of: fattening value, slaughter value (including detailed dissection of the 5 most valuable cuts) and the economic and commercial value of the carcass. Although the experimental group was characterised by lower daily gains, higher feed intake, and thus a less favourable feed conversion ratio, the cost of feeding these fattening pigs was PLN 3.21 significantly lowerr in the first 21 days of the experiment and PLN 41.69 lower over the subsequent 98 days of the experiment compared to the control group. Thus, the difference between the total costs of feeding (119 days – the entire experiment) was PLN 44.9 . It was also found that the carcasses of the fattened pigs in the experimental group had statistically significantly lower backfat thickness and higher loin 'eye' height and carcass leanness, which in turn resulted in higher weight of valuable cuts. There was no effect of feeding modifications on the economic value (calculated according to the EUROP classification) and commercial value (calculated according to the unit price of individual cuts) of carcasses and half-carcasses and the commercial value of the five most valuable cuts. However, statistically significant differences were shown in the profit from fattened pig production. The production of fattened pigs from the experimental group was characterised by a higher profit by PLN 56.79 than the production from the control group. Based on the analysis of the results, a positive effect of substituting protein from soybean meal with a mixture of domestic protein components, i.e. peas, faba beans, sunflower meal and hemp and linseed cake was demonstrated primarily on the profit from fattened pig production.

Insect protein as a sustainable replacement for soybean meal in diets for growing pigs: effects on growth performance, plasma metabolites and gut inflammation

A. Román[1], I. Fernández-Fígares[1], M. Lachica[1], C. García-Contreras[1], R. Nieto[1]
[1] , Estación Experimental del Zaidín, CSIC, 1Department of Nutrition and Sustainable Animal Production, Profesor Albareda, 1, 18008 Granada, Spain

Research on insect protein in pig diets has expanded rapidly since the 2010s, although insects have long been part of natural animal diets and were occasionally used in traditional feeding systems. Our aim was to evaluate alternative protein sources, specifically proteins derived from two insect species (Tenebrio molitor and Hermetia illucens), as potential sustainable substitutes for soybean by assessing their effects on growth performance, plasma metabolites and intestinal inflammation. A total of thirty (Duroc × Pietrain) × (Landrace × Large-White) pigs were randomly assigned to three experimental groups: a control group fed soybean meal and two groups in which 100% of soybean protein as the major protein source was replaced with insect protein either from Tenebrio molitor or Hermetia illucens. Diets were isoproteic and isocaloric, meeting the animals' nutritional requirements and formulated according to the ideal protein concept. Pigs were individually housed under temperature-controlled conditions (22 ± 1 °C) with ad libitum access to feed and water and were weighed weekly. Initial and final body weights were 17 ± 0.8 kg and 62 ± 2.4 kg, respectively. Animals were slaughtered 10 weeks after the beginning of the trial, after 24 h fasting, by electrical stunning and immediate exsanguination. Samples of faeces from the rectum were collected for calprotectin analysis. Additionally, blood samples were processed to determine biochemical parameters (albumin, β-hydroxybutyrate, HDL-cholesterol, LDL-cholesterol, total cholesterol, creatine, glucose, lactate, triglycerides and urea). Treatment effects were assessed by analysis of variance with a significance level of 0.05. No significant differences were found for feed intake among groups (1556, 1611 and 1485 g of dry matter/day, for the control, Hermetia and Tenebrio groups, respectively; SEM = 64.4; $P > 0.05$) indicating no differences in palatability of experimental diets. No significant differences between control and insect-fed groups were found regarding average daily gain, although insect-fed groups differed (848, 926 and 749 g/day, for the control, Hermetia and Tenebrio groups, respectively; SEM = 34.9; $P < 0.01$). There were significant differences for feed use efficiency. The highest value was for the Hermetia group, followed by the control and the Tenebrio groups (0.545, 0.575, 0.504; respectively; SEM = 0.005; $P < 0.001$). Regarding plasma biochemical metabolites, no significant differences were observed ($P > 0.05$), except for albumin, which was lower in the Hermetia group, compared with the control and Tenebrio groups (31.1, 36.3 and 38.3 g/L, respectively; SEM = 0.97; $P < 0.001$). Likewise, there were no differences in the levels of faecal calprotectin (1.99, 1.50 and 1.23 ng/g, for the control, Hermetia and Tenebrio groups; SEM = 0.47; $P > 0.05$). The results indicate that complete replacement of soy protein did not negatively affect growth performance, plasma biochemical parameters and markers of intestinal inflammation enhancing the sustainability of pig production without compromising animal performance. Circular protein ingredients from fungal fermentation and blue mussel cultivation: ileal digestibility in broiler chickens

T. Vasileiou[1], E. Ivarsson[1], H. Wall[1]
[1] Swedish University of Agricultural Sciences, Applied Animal Science and Welfare, Ulls väg 26, 750 07 Uppsala, Sweden

Feed production is a major contributor to the environmental impact of animal-based food systems through greenhouse gas emissions, land use, and nutrient losses. In the Baltic Sea region, eutrophication caused by excess nutrient inputs remains a critical environmental challenge. Circular feed ingredients that recycle nutrients from industrial sidestreams and marine ecosystems may contribute to more sustainable animal production. Modern broiler production has evolved through genetic selection to produce high-yielding animals with excellent feed efficiency. These birds require high levels of digestible amino acids which today to a high extent originate from traditional protein sources like soybean meal. Globally, feed production accounts for 50-60% of broiler production's environmental impact, with soybean meal (15-25% diet inclusion) contributing significantly due to production and transportation. Novel circular highly digestible protein sources could partially replace soy thus improving the environmental performance of broiler production. The objective of this study was to evaluate the nutritional value and apparent ileal digestibility of novel circular protein ingredients in broiler chickens. A digestibility trial was conducted with 192 Ross 308 broiler chickens allocated to four dietary treatments. A conventional wheat–soybean meal diet served as control, while experimental diets replaced 20–25% of the control diet with blue mussel (Mytilus spp.) meal, Neurospora intermedia mycoprotein, or Paecilomyces variotii mycoprotein. The mycoproteins were produced through fermentation-based processes using food and industrial by-products, whereas mussel meal was sourced from cultivated blue mussels in the Baltic Sea. All ingredients represent locally produced, circular feed resources with low land-use requirements. According to analysis all test ingredients exceeded 30% crude protein (CP) on a dry matter (DM) basis. Mussel meal had the highest CP content of approximately 65%, and lysine and methionine contents of 49.3 and 15.4 g/kg DM, respectively. P. variotii had approximately 50% CP and lysine and methionine contents of 31.9 and 7.2 g/kg DM. Corresponding figures for N. intermedia was 30% CP and 15.9 and 4.8 g/kg DM content of lysine and methionine, respectively. Apparent ileal digestibility of organic matter (OM), CP, and amino acids was determined. All experimental diets showed CP and amino acid digestibility values comparable to the control diet, with some exceptions. Among individual amino acids, leucine and aspartic acid displayed significant differences ($P<0.05$), with digestibility coefficients for P. variotii being higher than those for N. intermedia. A significant difference ($P<0.01$) was observed in the OM, with control diet having the highest digestibility coefficient and P. variotii the lowest. In conclusion, fermentation-derived mycoproteins, particularly P. variotii, and mussel meal demonstrated promising CP and amino acid levels as well as favourable digestibility characteristics in broiler diets. These findings support their potential role as circular, low-impact feed ingredients contributing to more sustainable and resilient poultry feed supply chains.

From Winery By-Product to Functional Feed Additive: Polyphenol-Enriched Natural Deep Eutectic Solvents on Antioxidant Defense and Gut Morphology in Meat-Type Quails

G. Pugliese[1], C. Losacco[1], V. Roselli[2], P. Iommelli[3], L. Piemontese[2], V. Tufarelli[1]

Casamassima km 3, 70010 Valenzano, Bari, Italy, [2] University of Bari Aldo Moro, Department of Pharmacy-Pharmaceutical Sciences, Campus Universitario "Ernesto Quagliariello" Via E. Orabona, 4, 70125 Bari, Italy, [3] University of Rome "Tor Vergata", Department of Experimental Medicine, Via Montpellier 1, 00133 Rome, Italy

The increasing environmental impact of food and agro-industrial waste represents a major global concern. Among extensively cultivated fruit crops, grape (Vitis vinifera L.) produces large amounts of pomace as the primary solid byproduct of winemaking. This residue is a valuable source of bioactive compounds, such as polyphenols, with recognized health-promoting properties. To recover these high-value molecules, a sustainable green extraction approach based on Natural Deep Eutectic Solvents (NaDES) was applied starting from grape pomace (cv Sangiovese) collected in Apulia Region of Southern Italy, in accordance with the principles of green chemistry and circular economy. A NaDES-based edible and ready-to-use choline chloride/ascorbic acid (ChCl/AA) (2:1; mol/mol + 40% water) polyphenolic extract, previously characterized for its chemical composition and biological activity, was used as feed supplement. Thus, this study aimed to evaluate the effects of a natural feed supplement on the productive performance, serum components, oxidative status and gut histomorphology of growing quails. A total of 120 unsexed 7-day-old growing Japanese quails were randomly assigned to three experimental groups (n = 40 per group), with each group further divided into four replicates (10 per replicate), up to 42-days of age. The control group received a basal diet without additive, while the experimental groups were supplemented with ChCl/AA NaDES (DES) or polyphenol-enriched NaDES (E-DES) at a level of 0.3% diet (3 g/kg diet), respectively. The results indicated that dietary treatments did not significantly affect growth performance, meat nutritional composition, or the majority of serum biochemical parameters in quails. Notably, supplementation with polyphenol-enriched NaDES enhanced the redox status of growing quails, as evidenced by a significant improvement in serum lipid profile parameters, increased total antioxidant capacity (TAC), superoxide dismutase (SOD), and glutathione peroxidase (GPx) activities, and reduced malondialdehyde (MDA) concentrations compared with the other groups. Furthermore, quails receiving the E-DES diet exhibited significantly improved antioxidant markers in breast muscle tissue, including higher SOD, catalase (CAT), and GPx activities, along with lower MDA levels. Intestinal histomorphological analysis, a key indicator of gut health, revealed that E-DES supplementation significantly increased villus height and width, suggesting enhanced absorptive capacity. In conclusion, these findings support E-DES as an innovative and sustainable feed additive that enhances antioxidant status and intestinal morphology without impairing productive performance. Furthermore, green solvent extractions offer a strategic approach to valorizing agro-industrial by-products, converting waste streams into high-value natural bioactive supplements in line with circular economy principles and sustainable poultry production.

In vitro large intestinal fermentation of Iberian and Landrace pigs fed lentil, chickpea and soybean diets

A. Román[1], I. Mateos[2], N. Merino[2], C. Saro[2], A. Díaz[2], R. Nieto[1], M. Lachica[1,1], C. García-Contreras[1], M. Lachica[1,1], I. Fernández-Fígares[1], M. J. Ranilla[2]

Locally grown lentils and chickpeas can replace soybean in pig diets, but information on their in vitro fermentation compared with soybean is limited. In addition, the diet of the donor pig may influence the fermentation capacity of the inoculum used in in vitro assays. This study evaluated the effect of donor pig diet on intestinal fermentation and the fermentative characteristics of lentils and chickpeas compared with soybean. Twenty-four (Duroc × Pietrain) × (Landrace × Large White) pigs (14 ± 0.3 kg) were allocated to three dietary groups: a control diet with soybean meal and two diets in which 50% of soybean protein was replaced by local legumes (culled chickpeas or lentils). Diets were isoproteic and isocaloric and met animal requirements. Pigs were individually housed at 22 ± 1 °C with ad libitum access to feed and water. After 10 weeks, pigs were slaughtered (66 ± 0.9 kg) and rectal faeces were collected and frozen (−20 °C) until incubation. On the incubation day, samples were thawed at 5 °C and pooled (four pools of two pigs per diet: soybean, lentil, chickpea). Bottles containing substrates (soybean, lentil, chickpea) were incubated at 39 °C for 24 h in duplicate using inoculum prepared from rectal content of each diet group.Data were analysed using a mixed model including substrate (soybean, lentil, chickpea), donor pig diet (soybean, lentil, chickpea) and their interaction as fixed effects, and donor pig (inoculum) as a random effect. Gas production, short-chain fatty acids (SCFA) and ammonia were measured. Incubations and analyses followed Pardo et al. (Animals 2023 13:1102).Donor pig diet did not affect 24 h gas production (852 ± 42 µmol/g; $P > 0.10$). Inoculum from pigs fed lentil diets showed greater dry matter disappearance than soybean, with chickpea intermediate (57, 54, 53% ± 1.0 for lentil, chickpea, soybean; $P < 0.05$). Ammonia-N concentration was higher with lentil than soybean diets (254, 298, 253 mg N/L ± 9.2 for soybean, lentil, chickpea; $P < 0.01$). Total SCFA production was greater with lentil than soybean diets, with chickpea intermediate (3760, 4719, 4289 µmol/g ± 186; $P < 0.01$). The same pattern occurred for acetate (2921, 3522, 3291 µmol/g ± 143; $P < 0.001$). Butyrate was highest with lentil, followed by chickpea and soybean (753, 647, 539 µmol/g ± 36; $P < 0.01$). Propionate did not differ among inocula (175 µmol/g ± 36; $P > 0.10$).Regarding substrate effect, lentil and chickpea fermented more than soybean (868, 1105, 584 µmol/g ± 42 for soybean, lentil, chickpea; $P < 0.001$). Chickpea showed greater dry matter disappearance than soybean, whereas lentil was lower (56, 49, 60% ± 1.0 for soybean, lentil, chickpea; $P < 0.001$). Ammonia-N concentration did not differ among substrates (267 mg N/L ± 9.2; $P > 0.10$). Chickpea produced the most total SCFA, followed by soybean and lentil (4170, 3614, 4984 µmol/g ± 186; $P < 0.001$). Acetate was lowest with lentil, with no differences between soybean and chickpea (2694, 3368, 3671 µmol/g ± 143; $P < 0.001$). Butyrate was highest with chickpea, followed by lentil and soybean (409, 621, 909 µmol/g ± 105; $P < 0.001$). Propionate did not differ among substrates (175 µmol/g ± 36; $P > 0.10$). In conclusion, donor pig diet did not affect gas production, but lentil diets increased SCFA, acetate, butyrate and ammonia compared with soybean diets. Chickpea showed the greatest fermentability, with higher SCFA production and dry matter disappearance.

Sugar beets to support the ensiling of feed for pigs and poultry

C. Visscher[1], A. Godglück[1], C. Arnold[1], C. H. Heuer[2], U. Bedenk[2], A. Von Felde[2], R. Hölscher[3]
[1] University of Veterinary Medicine Hannover, Institute for Animal Nutrition, Bischofsholer Damm 15, 30173 Hannover, Germany, [2] KWS SAAT SE & Co. KGaA, Grimsehlstrasse 31, 37555 Einbeck, Germany, [3] Hölscher + Leuschner GmbH & Co. KG, Siemensstrasse 15, 48488 Emsbüren, Germany

In the future, the safe and cost-effective storage of feed for pigs and poultry may become increasingly relevant. The vulnerability of supply chains means it is sensible to store larger quantities of feed directly on farms, ensuring that at least the current stock of animals can be fed until the end of the fattening period. Traditional storage capacities are rarely available in sufficient quantities nowadays and building them from scratch is very expensive. This exploratory study aims to produce mixed silage using washed and chopped sugar beets, as well as various types of grain, such as corn in the form of high moisture corn grain, wheat and rye, which can be easily, cheaply and safely stored in a bunker silo. For the silage trials, a total of approximately 1,000 tonnes of mixed silage, consisting of corn (C), wheat (W) and rye (R) each mixed with sugar beets (SBxC, SBxW or SBxR), was ensiled. The wheat and rye mixtures contained 30% sugar beets and 70% grain on a fresh matter basis. The high moisture corn grain mix contained approximately 15% sugar beets. A standard corn cob mill was used to grind the raw materials. The material was ensiled in a bunker silo. Once ensiling was complete, a representative sample of each silage was taken for analysis in the feed laboratory to determine its energy and nutrient content, as well as its ensiling quality. Following ensiling, the mixtures (SBxC, SBxW and SBxR) exhibited low pH values (3.71, 3.84 and 3.97), low ethanol content (g/kg DM: 1.96, 1.69 and 1.18), low viscosity (mPa·s: 1.35, 1.46 and 1.49), and low yeast (cfu/g: 3.5×10^3/–/0.5×10^3) and mould content ($<10^3$/–/$<10^3$). There was little difference in the levels of acetic acid (g/kg DM: 8.44/8.55/7.82), propionic acid (g/kg DM: 0.16/0.13/0.17) and n-butyric acid (g/kg DM: 0.13/0.37/0.37), nor in the levels of enzyme-soluble substances (g/kg DM: 952/939/936) or calorific value (MJ/kg DM: 18.7/18.6/18.6). Mixed silage made from sugar beets is an inexpensive feed for pigs. With the necessary technical adjustments, it could also be used for fattening poultry. The advantages lie in the high number of lactic acid bacteria, which can promote animal health when consumed. At the same time, this preservation method enables the cost-effective creation of a stable feed supply for monogastric animals using existing harvesting, processing and silage technology.

Common vetch seeds as home-grown protein feed for growing-finishing pigs

S. Witten[1], J. Wiskandt[1], M. T. Machner[1], R. Bussemas[1], K. Aulrich[1]
[1] Johann Heinrich von Thünen Institute, Institute of Organic Farming, Trenthorst 32, 23847 Westerau, Germany

Agricultural systems rely on amino acid supplying feedstuffs for monogastric animals. Home-grown protein feeds, like grain legumes, can contribute to circular systems and improve the resilience of agricultural systems with pig husbandry. Common vetch (Vicia sativa L.) has low demands on its habitat (Nguyen et al. 2020), so it can also grow on acidic soils and in dry regions. Its seeds contain high amounts of crude protein (up to 321 g kg^{-1} according to Chen et al. 2022) with higher proportions of methionine compared to other legumes (Seabra et al. 2001). However, feeding recommendations are scarce and the contained pyrimidine glycosides and cyanoalanine toxins might have a negative effect on palatability and health (Enneking 1994). The objectives of the study were to examine the use of diets for growing-finishing pigs with up to 20 % of grain legumes and to study the effects of raw vetch seeds of the variety Slovena (not specifically low in toxins; Höhne et al. 2025) on the performance of growing-finishing pigs. The first trial started in November 2025. A total of 80 pigs of a commercial breed were held on the organic experimental station of the Thünen Institute and fed a three-phase diet (growing phase 1: GP1 <50 kg body mass (BM), growing phase 2: GP2 50-75 kg BM, finishing phase: FP >75 kg BM) containing 29 (GP1+2) and 30 % (FP) grain legumes. In the control group (C), field peas and field beans were used as grain legumes and in GP1 49.5 % cereals and 18 % oilcakes, in GP2 57.2 % cereals and 11 % oil cakes, and in FP 64.2 % cereals and 3 % oil cakes were fed. In the vetch group (V), grain legumes were exchanged with vetch, which accounted for 10, 15, and 20 % of the diet in GP1, GP2, and FP, respectively. The other components were adjusted to gain equal energy and lysine concentrations between C and V (1 % less oil cakes in V). The feed was pelleted and supplied ad libitum. The health status (medical treatments) was continually monitored. Pigs and feed removals were weighed weekly. Pigs were slaughtered when weighing >119 kg. Paired t-tests were conducted to compare daily body mass gains (BMG) and feed conversion (FC) between both feeding groups. The pigs had mean BMG of 837 ± 52 g in GP1 and 1077 ± 72 g in GP2 and no significant differences between the feeding groups were observed. FC also did not differ significantly between the groups and was 2.2 in GP1 and 2.8 in GP2. Preliminary evaluations of 75 (37 C, 38 V) of the 80 pigs showed a mean BMG in FP of 1141 ± 62 g without significant differences between feeding groups. No feeding-related medical treatments were conducted. Previous studies have described that over 20 % raw common vetch seeds can be used in piglets (Seabra et al. 2001) and a low-toxin variety can be suitable in diets for growing pigs (Collins et al. 2005). The use of Slovena vetch seeds fed over the whole growing-finishing period of pigs in increasing amounts of 10 to 20 % of the diet did not impede growth or health in our first trial. To ensure that raw vetch seeds can be used safely in pig husbandry, examinations of carcass characteristics, meat quality, and blood parameters as well as consecutive trials are planned. Growth performance, nutrient digestibility, and nitrogen and phosphorus balance and excretion in fattening rabbits fed a diet primarily based on agro-food by-products

L. Zita[1], Z. Volek[2], P. Šufliarský[2], V. Plachý[3], P. Kočár[4]
[1] Czech University of Life Sciences Prague, Department of Animal Science, Kamýcká 129, 16500 Prague - Suchdol, Czech Republic, [2] Institute of Animal Science, Department of Nutritional Physiology and Animal Product Quality, Přátelství 815, 10400 Prague - Uhříněves, Czech Republic, [3] Czech University of Life Sciences Prague, Department of Microbiology, Nutrition and Dietetics, Kamýcká 129, 16500 Prague - Suchdol, Czech Republic, [4] Kočár's Rabbit Farm, Ratibořice 11, 67551 Jaroměřice nad Rokytnou, Czech Republic

Population growth and resource limitations will drive the transition of livestock farming, including rabbit meat production, from linear to circular value-added systems. In this context, replacing imported feeds with local protein sources and agro-food by-products can enhance the sustainability of livestock feeding. In this respect, the rabbit may be an ideal species for substituting food-grade feed materials with the aforementioned local resources in its diet due to its ability to efficiently digest high-fibre feeds. In fact, agro-food by-products are rich in dietary fibre. This study compared a conventional fattening diet (CF diet; alfalfa meal, soybean meal, wheat bran, sugar beet pulp, oats, and barley) with a fattening diet based primarily on local protein source and agro-food by-products (F-AFB diet; rapeseed cake, wheat bran, sugar beet pulp, corn distillers' grains with solubles, maize bran and flour, buckwheat hulls, and sunflower hulls), in which alfalfa meal, soybean meal, oats, and barley were completely excluded. Both diets had similar levels of crude protein (CP), neutral detergent fibre (NDF), acid-detergent fibre (ADF), limiting amino acids, and digestible protein. The F-AFB diet contained slightly higher acid-detergent lignin and ether extract, and slightly lower starch content. A total of 180 Hyplus rabbits (32 days of age) were allocated into two groups of 90 rabbits each and were fed either the CL diet or the F-AFB diet for growth performance evaluation. The fattening period lasted 42 days, after which the rabbits were 74 days old. In addition, total tract apparent digestibility (CTTAD) of the diets and nitrogen and phosphorus output were determined in 10 rabbits per treatment. No significant differences were observed in the final live weight of the rabbits (on average 2512 g), average daily feed intake (on average 135 g), or feed conversion ratio (on average 3.16). Neither mortality nor morbidity was observed during the entire fattening period, which represents an important finding of the study. Rabbits fed the F-AFB diet had significantly lower CTTAD of CP and starch, whereas CTTAD of NDF and phosphorus was significantly higher compared with the CF diet. Total nitrogen excretion and nitrogen retained did not differ between diets; however, the nitrogen retention coefficient was slightly lower in rabbits fed the F-AFB diet than in those fed the CF diet (0.40 vs. 0.45; $P = 0.042$). In contrast, phosphorus retained and the phosphorus retention coefficient were lower in rabbits fed the CF diet than in those fed the F-AFB diet (0.31 vs. 0.42 and 0.28 vs. 0.33, respectively; $P = 0.004$). Based on the obtained results, the F-AFB diet may represent a promising alternative to conventional feeding strategies. These findings support the concept of utilising local protein sources and agro-food by-products in rabbit nutrition and may contribute to the progressive integration of rabbit meat production into circular value-added feeding systems. This research was funded by the Ministry of Agriculture of the Czech Republic under grant QL24010136.

Faecal volatile fatty acids production in growing pigs fed local legumes partially replacing soybean meal as main dietary protein source

A. Román[1], I. Mateos[2], C. Saro[2], A. Díaz[2], N. Merino[2], C. García-Contreras[1], M. Lachica[1], I. Fernández-Fígares[1], M. J. Ranilla[2]

[1] CSIC-EEZ, Nutrition and Sustainable Animal Production, Profesor Albareda 1, 18008 Granada, Spain, [2] Universidad de Leon, Producción Animal, Campus de Vegazana, 24071 León, Spain

Identifying alternative protein sources is a priority in pig production to reduce reliance on imported soybean meal. Local legumes such as peas, chickpeas and lentils are promising candidates due to their low environmental footprint, favorable nutritional profile and fermentable fiber content. The fiber fraction strongly influences hindgut microbial fermentation, producing volatile fatty acids (VFA) that may affect gut health and energy utilization. The aim of this study was to evaluate local protein sources (peas, chickpeas and lentils) as sustainable alternatives to soybean by assessing their effects on faecal fermentation and volatile fatty acid (VFA) production in a commercial pig breed. Thirty-two (Duroc × Pietrain) × (Landrace × Large White) pigs were randomly assigned to four groups: a control diet with soybean meal and three diets in which 50% of soybean protein was replaced by local legumes (peas, culled chickpeas or culled lentils). Diets were isoproteic and isocaloric, meeting animal requirements and formulated according to the ideal protein concept. Pigs were slaughtered after 10 weeks following a 24 h fast by electrical stunning and immediate exsanguination. Rectal faecal samples were collected and stored at −20 °C until VFA analysis. Briefly, 10 g of frozen faeces were acidified with 2 mL/g of 0.5 N HCl, vortexed and left for 10 min. A 2 mL aliquot was then centrifuged (16 000 × g, 15 min, 4 °C). Subsequently, 800 µL of supernatant were mixed with 500 µL metaphosphoric–crotonic acid and incubated overnight at 4 °C. Samples were centrifuged again under the same conditions, and the supernatant transferred to gas chromatography vials and stored at −20 °C until analysis. Acetate, propionate, isobutyrate, butyrate, isovalerate and valerate were quantified by gas chromatography using crotonic acid as an internal standard. Treatment effects were evaluated by one-way ANOVA ($P < 0.05$), with the pig as the experimental unit. No significant differences were observed in total VFA production (153, 139, 177, 153 mmol/L for control, chickpea, pea and lentil diets; SEM = 14.3; $P > 0.05$) or in the molar proportions of acetate (mean 0.672; SEM = 0.019), isobutyrate (0.020; SEM = 0.001), isovalerate (0.024; SEM = 0.002) and valerate (0.018; SEM = 0.002) ($P > 0.05$). However, butyrate proportion differed among treatments, being higher in pigs fed peas than in control and chickpea groups, with lentils showing intermediate values (0.102, 0.072, 0.072, 0.090, respectively; SEM = 0.084; $P < 0.05$). Although individual VFA differed, total faecal VFA remained similar among treatments. Higher butyrate proportions in pea and lentil diets may indicate beneficial effects on gut health when partially replacing soybean in growing pigs. Funded by the EU project Facilitating Innovations for Resilient Livestock Farming Systems, abbreviation: Re-Livestock (reference number: 101059609).

Effects of high-level inclusion of chopped and pelleted alfalfa on starter intake and growth performance in dairy calves.

R. Colleluori[1], E. Davis[2], K. Hare[2], P. Górka[3], A. Formigoni[1], G. Penner[2]
[1] University of Bologna, Via Tolara di Sopra, 50, 40064 Bologna, Italy, [2] University of Saskatchewan, Campus Drive 51, S7N 5A8 Saskatoon, Canada, [3] University of Agriculture in Krakow, Al. Mickiewicza 21, 31-120 Krakow, Poland

According to recent European and Canadian guidelines, calves are recommended to receive high milk allowances, often requiring a later weaning age. At the same time, commonly used high-starch starter diets are associated with an increased risk of ruminal acidosis and parakeratosis. Delayed weaning may therefore represent an opportunity to increase the inclusion of high-quality forage in calf diets. This study aimed to evaluate the effects of partial substitution of a conventional starter with alfalfa on feeding behaviour and growth performance in dairy calves. Eighty-eight Holstein × Jersey crossbred calves were enrolled at day 3 of age. Calves were blocked by body weight and breed composition, and assigned to one of the three dietary treatments: high starch starter (HS), starter including 30% chopped alfalfa (CA), or starter including 30% pelleted alfalfa (PA). Compared with HS, CA and PA diets differed in starch (35% vs. 25% DM) and soluble fiber content (5% vs 10% DM) while remaining isoenergetic and isonitrogenous. All calves were provided 20% of their body weight (BW) as whole milk from day 7 to 28, and were weaned at day 70 using a gradual step-down weaning approach. Calves were individually housed until day 77 and starter and milk dry matter intake (DMI) were recorded every two days throughout the study. Body weight was measured weekly and body measurements (heart girth, withers height and hip width) were collected on days 3 and 70. Age at first starter intake (AFI; ≥50 g DM/day) and gain-to-feed ratio (G:F; ADG/milk and starter DMI) were calculated. Data were analyzed using a mixed model with treatment as fixed effect, BW on day 3 as a covariate when relevant, and repeated measurements were modeled including age as fixed effect and calf as random effect. Milk intake did not differ among treatments. From day 49 to 70, starter DMI diverged among treatments with HS calves consuming 1.05 kg/d compared with 0.77 kg/d for PA ($P = 0.01$), while CA (0.93 kg/d) did not differ from either group. A similar pattern occurred for cumulative starter intake, such that calves consumed 42.5, 37.1, and 32.7 kg for HS, CA, and PA, respectively ($P < 0.01$). Differences in starter intake were confined to late pre-weaning phase, as no treatment effects were observed after weaning. At day 77, PA calves were lighter than HS (84.4 vs. 89.6 kg; $P = 0.04$), while CA (86.6 kg) did not differ from either treatment. Moreover, PA tended to have an older AFI than HS (29 vs. 24 days; $P = 0.07$) while a tendency for greater wither height variation was observed for CA compared with HS and PA (16.66 vs. 15.59 and 14.81 cm; $P = 0.08$). Milk intake, ADG, thoracic circumference, hip width, pre- and post-weaning G:F did not differ among treatments. Overall, differences consistently emerged between HS and PA; whereas, CA showed intermediate responses but did not differ from HS. These results suggests that pelleted alfalfa inclusion at a high level impaired starter DMI, growth, and feed efficiency. In contrast, the same alfalfa presented as chopped forage did not compromise performance, highlighting the importance of forage physical structure in pre-weaning diets. Further evaluation of long-term performance, nutrient digestibility, and gastrointestinal development will provide additional insight into the physiological processes driving these responses.

Nutrient intake and growth performance of Holstein calves supplemented with rumen-partially metabolizable methionine analog

P. H. Cavalcante Ribeiro[1], R. J. De Oliveira[1], M. E. Pizzo Silva Ferreira[1], M. Resende Mecchi[1], D. Domingues Millen[1]
[1] UNESP, Animal Science, Via de Acesso Prof. Paulo Donato Castellane s/n, 14.884-900 Jaboticabal/São Paulo, Brazil

Methionine (Met) is the first limiting amino acid in young ruminants. Besides, low ruminal activity limits microbial protein synthesis, making the diet the primary source of Met. A rumen-partially metabolizable Met analog (HMBi) has been reported to improve body weight [BW] in calves, possibly due to a ruminal effect. However, few studies have been conducted, limiting clear recommendations for HMBi doses for calves. This study aimed to evaluate nutrient intake and growth performance of Holstein calves supplemented with HMBi during the pre- and post-weaning periods. Thirty-six male Holstein calves (7 ± 3 days of age; 40.26 ± 4.49 kg of BW and 9.2 ± 0.5 brix for serum total protein) were used in a randomized block design with three birth seasons as blocks, and supplemented with 0 (control), 8, or 16 g day^{-1} of HMBi. Within each block, one calf was slaughtered at 7 days of age, and another was fed a liquid diet exclusively throughout the preweaning period (a total of 42 animals). Calves were fed 8 L day^{-1} of milk replacer (12.5% solids), concentrate (ground corn, soybean meal, minerals, and vitamins [88.7% dry matter [DM]; 26.1% crude protein [CP]; 13.5% neutral detergent fiber [NDF]; 35.4% starch), and Tifton hay (81.2% DM; 10.1% CP; 75.6% NDF). Calves were weaned at 56 days of age using a gradual weaning protocol. After weaning, calves were fed a concentrate diet (84.8% DM; 21.2% CP; 13.3% NDF; 40.1% starch) and Tifton hay until they reached 126 kg BW. Concentrate, hay, and refusals were weighed daily to determine nutrient intake. Animals were weighed at the beginning of the study (7 days of age) and at every 7-day interval thereafter until slaughter (18 animals slaughtered at 56 days of age and 18 animals slaughtered at 126 kg BW). Data were analyzed as orthogonal contrasts to evaluate linear and quadratic effects ($P \leq 0.05$), using SAS 9.4. Initial age and measurements of calves fed milk replacer exclusively were tested as covariates ($P \leq 0.05$). The HMBi supplementation did not affect DM intake (DMI) of milk replacer (866.1 g day^{-1}) or hay (12.5 g day^{-1}), but linearly reduced ($P \leq 0.03$) concentrate DMI (120.9, 82.1, and 58.8 g day^{-1}), NDF intake (NDFI; 40.2, 35.0, and 32.08 g day^{-1}), and starch intake (61.2, 46.8, and 37.7 g day^{-1}) for 0, 8, and 16 g HMBi day^{-1}, respectively, at pre-weaning. The CP intake (CPI; 217.3 g day^{-1}), BW at weaning (61.1 kg), average daily gain (ADG; 0.354 kg day^{-1}), and gain:feed ratio (0.36) were not affected by HMBi doses during the pre-weaning period. At post-weaning, HMBi linearly increased (P=0.02) hay DMI (0.121, 0.151 and 0.163 kg day^{-1}) and reduced (P=0.03) concentrate DMI (2.46, 2.39 and 2.12 kg day^{-1}) for 0, 8, and 16 g HMBi day^{-1}, respectively, but did not affect total DMI (2.47 kg day^{-1}), NDFI (0.442 kg day^{-1}), starch intake (1.05 kg day^{-1}), CPI (0.55 kg day^{-1}), final BW (129.6 kg), ADG (0.98 kg day^{-1}), and gain:feed ratio (0.40). During pre- and post-weaning, the reduction in concentrate DMI with increasing HMBi doses may reflect greater metabolic satiety due to enhanced Met availability, a phenomenon supported by similar BW development in calves. Additionally, HMBi itself may limit intake by altering diet palatability, as observed in studies using amino acid sources in both solid and liquid diets. The greater the DMI, the more it can contribute to improved gastrointestinal development and health. The HMBi supplementation at levels up to 16 g day^{-1} reduced concentrate, starch, and fiber intake at pre- and post-weaning, without affecting body weight gain.

Ruminal fermentation and papillae development of calves supplemented with rumen-partially metabolizable methionine analog

P. H. Cavalcante Ribeiro[1], R. J. De Oliveira[1], J. C. Paterno[1], M. L. Pereira[1], A. Faria De Toledo[1], D. Domingues Millen[1]
[1] UNESP, Animal Science, Via de Acesso Prof. Paulo Donato Castellane s/n, 14.884-900 Jaboticabal/São Paulo, Brazil

A high ruminal fermentation rate and the production of short-chain fatty acids (SCFA) can benefit rumen papillae development and increase digestive capacity in calves. Besides, the rumen-partially metabolizable methionine analog (HMBi) has been known to alter ruminal fermentation patterns in adult ruminants. This study aimed to evaluate ruminal fermentation and papillae development in Holstein calves supplemented with increasing doses of HMBi. Thirty-six male Holstein calves (7 ± 3 days of age; 40.26 ± 4.49 kg body weight [BW]) were used in a randomized block design with three birth seasons as blocks and supplemented with 0 (control), 8, or 16 g day^{-1} HMBi. Within each block, one calf was slaughtered at 7 days of age, and another was fed a liquid diet exclusively throughout the preweaning period (a total of 42 animals). Calves were fed 8 L day^{-1} of milk replacer (12.5% solids), concentrate (ground corn, soybean meal, minerals, and vitamins [26.1% crude protein [CP]; 13.5% neutral detergent fiber [NDF]; 35.4% starch), and Tifton hay (10.1% CP; 75.6% NDF). Calves were weaned at 56 days of age using a gradual weaning protocol. After weaning, calves were fed a concentrate diet (21.2% CP; 13.3% NDF; 40.1% starch) and Tifton hay until they reached 126 kg BW. Eighteen calves were slaughtered immediately after weaning, and the remaining 18 were slaughtered upon reaching 126 kg BW. At harvest, rumen contents were collected to determine the SCFA profile, pH, and NH3-N. Fragments (1 cm²) from the cranial and ventral sacs of the rumen were collected for morphometrics of ruminal papillae. Data were analyzed as orthogonal contrasts to evaluate linear and quadratic relationships ($P \leq 0.05$), using SAS 9.4. Initial age and measurements of calves slaughtered at the beginning of the study and those fed milk replacer exclusively were tested as covariates ($P \leq 0.05$). The HMBi doses did not affect total SCFA (83.13 mM), acetate (48.76 mM), propionate (38.57 mM), isobutyrate (1.02 mM), isovalerate proportion (1.26 mM), NH3-N (17.06 mg dL^{-1}), pH (5.99), number of papillae (NMP; 211), papillae area (MPA; 0.16 mm²), absorptive surface area (ASA; 3.46 mm²/mm²), papillae height (4.40 mm²) and width (2.24 mm²) and keratinized layer thickness (KLT; 14.70 µm) at weaning. Butyrate (7.76, 10.47, and 5.93 mM) and valerate proportion (2.31, 2.74, and 1.99 mM) showed a quadratic response for 0, 8, and 16 day-1 HMBi, at weaning. At post-weaning, propionate proportion reduced (45.44, 43.75 and 39.93 mM) and isobutyrate proportion (1.68, 2.31 and 2.70 mM), and ASA (14.03, 16.88 and 20.02 mm²/mm²) increased linearly, while butyrate proportion (5.86, 5.12 and 6.50 mM) and papillae height (5.43, 6.48 and 5.30 mm2) showed quadratic behavior for 0, 8 and 16 g day^{-1} HMBi. Rumen total SCFA (115.95 mM), acetate (43.07 mM), isovalerate (2.29 mM), and valerate proportion (3.56 mM), NH3-N (23.61 mg dL^{-1}), pH (5.95), NMP (97), MPA (1.80 mm²), papillae width (2.89 mm²), and KLT (29.87 µm) were not affected by HMBi doses at post-weaning. The greater butyrate concentration with 8 g day^{-1} HMBi at pre-weaning suggests enhanced carbohydrate fermentation and a greater potential for ruminal papillae development, as observed in ruminal ASA in the post-weaning period for doses of 8 and 16 g day^{-1} of HMBi, resulting in greater epithelial absorption. The feeding of HMBi at 8 g day^{-1} during the pre-weaning period and 16 g day^{-1} during the post-weaning period may maximize ruminal epithelium development of calves. Overall, feeding HMBi altered the ruminal SCFA profile during the pre- and post-weaning periods.

Hybrid rye as a forage source for Holstein cows around parturition

L. Garcia[1], B. Brattain[2], Z. Mcdaniel[2], F. Cardoso[1]
[1] University of Illinois, Animal Sciences, 1207 W. Gregory Dr., 61801 Urbana, United States, [2] KWS Cerelas USA, Champaign, IL, 61822 Champaign, United States

Information on the use of hybrid rye as an alternative forage source to wheat straw in dry cow diets remains limited. Our first objective was to determine the effects of ensiling time (0, 30, 60, 90, and 150 d) on fiber composition of hybrid rye (KWS Progas, KWS Cereals USA, Champaign, IL) harvested at two maturities. Treatments were replicated once and assigned to one of two 4 ha plots of hybrid rye as follows: hybrid rye harvested at boot stage (BOO) and hybrid rye harvest at milky stage (MIL). Baled hybrid rye was transported by flat rack wagons (E-Z Trail Inc., Arthur, IL) from field to scale where each wagon weight was recorded. A total of 6 samples were removed directly from the bales using a forage sampler (Nasco Education, Fort Atkinson, WI) at their respective ensiling time then frozen for later analysis. For both objectives the statistical analyses were conducted using the MIXED procedure of SAS. At harvest, the average DM content for BOO and MIL was 16.9±0.01, and 29.0±0.06 %, respectively. Hybrid rye yield for BOO and MIL was 8.46 and 13.6 tons/acre, respectively. Rye silage in MIL had higher (P=0.002) concentrations of ADF (39.0%) than rye silage in BOO (34.0%). Rye silage in MIL had higher (P=0.03), concentrations of NDF (58.3%) than rye silage in BOO (54.8%). There was a treatment × time point interaction (P=0.03) in which rye silage in BOO had a lower concentration of starch at d 0, 30, and 60 (0.50, 0.75, and 0.15%, respectively) than rye silage in MIL (2.90, 2.70, and 1.85%, respectively). Rye silage in MIL had higher (P=0.04) concentrations of total acids (6.25%) than rye silage in BOO (4.19%). In conclusion, days ensiled negatively affected the nutritive profile and fermentation quality of hybrid rye harvested at milky stage but not for hybrid rye harvested at boot stage. Our second objective was to evaluate the effects of feeding hybrid rye baleage (KWS Cereals USA, Champaign, IL) from -32 ± 6 days relative to calving to 28 days in milk on performance of Holstein cows. Sixty-one multiparous pregnant Holstein cows, blocked by parity, previous 305-d mature-equivalent milk production, expected calving date, and BCS during the far-off dry period were assigned to 1 of 2 dietary treatments: total-mixed ration with wheat straw [(WS); 32.6% of dietary DM] or hybrid rye at the milky stage as the prepartum forage [(RM); 55.4% of dietary DM) in a randomized complete block design. After calving, half of the cows from each prepartum treatment group were assigned to a diet with alfalfa haylage (WSAH; RMAH; 25.2% of dietary DM) or a diet with hybrid rye at the boot stage (WSRB; RMRB; 13.2% of dietary DM) as the postpartum forage. Dry matter intake (DMI) and milk yield were obtained daily; body weight (BW) and BCS were measured weekly. During the prepartum period, there were no treatment effects observed for cows in WS and RM for DMI (12.3 and 12.5±0.24 kg/d, respectively; P=0.59), DMI as a percentage of BW (1.53 and 1.51±0.06%, respectively; P=0.84), BW (829.3 and 824.5±3.14 kg, respectively; P=0.25), BCS (3.54 and 3.54±0.04, respectively; P=0.93), or energy balance (2.54 and 2.50±0.61 Mcal/d, respectively; P=0.96). There was no effect of PRE (P=0.18) or POST (P=0.76) for milk yield. Cows in AH tended to have greater DMI (15.3±0.66 kg/d; P = 0.08) than cows in RB (14.1 ±0.66 kg/d) at week 1. Overall, hybrid rye harvested at the milky stage can replace wheat straw in controlled-energy dry cow diets without negatively affecting prepartum performance, and hybrid rye harvested at the boot stage can be included as a postpartum forage source without affecting early-lactation performance.

Carry-over effects of early postpartum protein supplementation on lactational performance, body weight, and nitrogen efficiency in dairy cows

S. E. Räisänen[1], T. Michou[1], M. R. Weisbjerg[1], M. Larsen[1]
[1] Aarhus University, Department of Animal and Veterinary Science, Blichers Allée 20, 8830 Tjele, Denmark

The objective of this on-going full lactation study was to investigate production and nitrogen-efficiency-related carry-over effects of supplemental protein provided to early postpartum dairy cows. A total of 41 Danish Holstein cows, of which 18 calving into their 2nd lactation and 23 calving into their 3rd or 4th lactation, were assigned to one of two treatments: 1) Control (lactating cow TMR consisting of % of dry matter (DM): 16.3% crude protein; 30.5% NDF, and 21.1% starch; n = 21), or 2) Boost [Control TMR + 4 kg/d of protein concentrate (42.3% crude protein, 7.9% NDF, 12.2% starch) during 1 to 7 days-in-milk (DIM), thereafter a gradual decrease by 200 g/d until DIM 28; n = 20]. After 28 DIM, all cows were fed the Control diet only. Data from calving up to 150 DIM were included in the current datasets. The protein concentrate was provided as a separate feed using the Roughage Intake Control System (RIC; Insentec BV) and the daily allowance for the Boost cows was adjusted according to DIM. All cows had ad libitum access to the basal TMR in RIC bins. Intakes of the protein concentrate and basal diet, as well as daily milk yield (MY) and body weight (BW) were recorded, and milk samples collected weekly from 2 milkings. The data were divided into two datasets with daily data for MY and DM intake (DMI) from DIM 1 to 28 and averaged weekly data from week 4 to 21. For energy-corrected milk yield (ECM), milk composition, and BW, data were average by week (week 1 to 21 of lactation). Data were analyzed using the lme function in R and the model included the fixed effects of treatment, DIM or lactation week, their interaction, and parity and the random effect of cow. The average concentrate intake for the Boost cows was 3.43 (±1.06) kg/d on DIM 1 to 7, and decreased on average 0.178 kg/d up to DIM 28. Overall, there were no difference between the treatments in total DMI during the first 28 DIM and up to week 14 of lactation, but Boost cows had around 1.6 kg/d greater ($P < 0.05$) DMI on week 15 to 18. Milk yield was on average 3.8 kg/d greater ($P < 0.05$) for the Boost cows across the first 28 d of lactation and remained 3.6 kg/d greater ($P < 0.05$; $P \leq 0.09$) after discontinuation of the protein supplementation on lactation weeks 4 to 11, 17, 18 and 21. Similarly, the Boost cows had or tended to have on average 3.7 kg/d greater ECM yield ($P < 0.05$; $P \leq 0.08$) across the 21 weeks of lactation. Milk true protein yield was around 10% greater on weeks 1 to 4 of lactation ($P < 0.05$), milk fat yield on average 11% greater on lactation weeks 4, 7, 11, 15, 19, and 21, and milk lactose yield on average 10% greater ($P < 0.05$) across the 21 lactation weeks for Boost cows. Milk urea concentration was 21 to 44% greater ($P < 0.05$) for Boost cows on lactation week 1 to 4, but was similar between the treatments thereafter. Nitrogen-Use-Efficiency was 8, 5, and 4 %-units lower ($P < 0.05$) for Boost cows on lactation week 1, 2, and 3, respectively, but did not differ between treatments across lactation weeks 4 to 21 being on average 35.9% (SEM = 0.95). Lastly, BW change did not differ between treatments. This study confirmed the potential of early postpartum protein supplementation to improve the lactational performance of dairy cows with positive carry-over effects up to at least 21 weeks of lactation. Further analysis will investigate the effects of the protein boost on nitrogen balance, and muscle and fat tissue mobilization. Future research should investigate the mechanisms behind the observed positive production response with carry-over effect, and potential role of individual AA in early lactation energy metabolism.

Impact of two levels of metabolizable protein and rumen-protected lysine and methionine for primiparous Holstein cows during the transition period and early lactation

E. S. O'Meara-Gossett[1], D. Martinez Del Olmo[2], J. Mateos Aguado[2], P. Mannina[2], E. Raffrenato[2], F. Cardoso[1]
[1] University of Illinois, Animal Sciences, 1207 W. Gregory Dr., 61801 Urbana, United States, [2] Kemin Industries, Inc, 1900 Scott Ave, 50317 Des Moines, United States

Efficient livestock production relies on accurate nutritional management and optimal replacement animal development. Heifers represent the future productive herd, and their growth, reproductive performance, and lifetime productivity are strongly influenced by early nutritional strategies. Proper evaluation of heifer development allows producers to ensure that animals reach appropriate body weight and physiological maturity at breeding, which is essential for improving fertility, longevity, and overall herd efficiency. Metabolizable protein (MP) is a critical component in ruminant nutrition as it represents the true protein available for absorption in the small intestine after ruminal digestion. Accurate determination of MP supply and requirements is essential to support growth, tissue development, and reproductive performance in heifers. Both insufficient and excessive protein supply can lead to reduced performance, inefficient nutrient utilization, and increased environmental nitrogen losses. Therefore, this study aimed to determine primiparous Holstein cows' performance when a standard MP (1,100 g MP/d) diet, without rumen-protected lysine (RPL) and rumen-protected methionine [RPM; Control; SMP]; a SMP diet with RPL [Kemin Industries Inc., Des Moines, IA; (0.54% RPL of DMI)] and RPM [Kemin Industries Inc., Des Moines, IA; (0.21% RPM of DMI); SMPAA], or high MP diet [(1,300 g of MP/d); HMP] were fed from -28 d to calving. Fifty-five primiparous Holstein cows were blocked by age at calving (months), dam PTA, sire PTA, expected calving date, and body condition score (BCS) during the far-off period and assigned to one of the three dietary treatments. Dry matter intake was recorded daily, and body weight (BW) and BCS were measured weekly. Prepartum energy balance (EBAL) was calculated weekly according to the NASEM (2021) equations. Colostrum was collected at the first milking after calving, weighed, and evaluated for IgG concentration using a colostrometer (Biogenics, Florence, OR) based on density correlation and Brix measurement using a digital refractometer (MISCO PA202x-400, Solon, OH). Colostrum samples were also chemically analyzed for fat content (ether extraction) and true protein (Kjeldahl method). Statistical analyses were performed using the MIXED procedure of SAS. Two treatment contrasts, SMP vs. SMPAA and SMPAA vs. HMP, were compared. Tukey's adjustment was used for the comparison of means. There were no differences between treatments or treatment by week interaction for DMI, BW, BCS, and EBAL ($P > 0.19$). No treatment differences were found for colostrum fat concentration, protein concentration, weight, IgG, or total solids $P > 0.18$. There was a tendency for cows in SMPAA to have a higher brix reading than cows in HMP (27.1 and 23.9, respectively; $P = 0.06$). Increasing metabolizable protein or supplementing RPM and RPL during the close-up period did not influence prepartum performance or colostrum quality. Evaluation of the subsequent lactation phase is needed to determine whether these treatments elicit carryover effects.

Effects of a multi-strain inoculant on alfalfa grass silage quality, digestibility, lactation performance and methane intensity in Holstein cows

G. Omoruyi[1,2], R. Scuderi[3], J. Green[1], A. Barkley[3], C. Ballard[1], C. Villot[4], S. Morisson[1], C. Byrne[4]
[1] William H. Miner Agricultural Research Institute, Chazy, 12921 NY, United States, [2] University of Vermont, Department of Animal and Veterinary Sciences, Vermont, 05405 VT, United States, [3] Lallemand Specialties Inc, Milwaukee, 53218 WI, United States, [4] Lallemand SAS, Rue des Briquetiers, 31700 Blagnac, France

Maximizing forage quality in dairy cattle diets offers several benefits for animal productivity and efficiency, but depends on optimal forage management. The objective of this study was to evaluate a multi-strain inoculant on alfalfa grass silage (AGS) quality, fiber digestibility, lactation performance, and methane intensity. Alfalfa grass was harvested at first cut and ensiled in small-scale bunkers (19.8m x 6.1m x 2.0m) for 124 days. Fresh material was either untreated (CON) or treated with a multi-strain inoculant containing Pediococcus pentosaceous, Lentilactobacillus buchneri, and L. hilgardii at 2.74×10^5 cfu/g. Silage was sampled at weeks 0, 2, 4, and 6 relative to the feeding trial at two sampling heights (50 and 150 cm from the bottom of the bunker face). Samples were analyzed for fermentation profiles, enumeration of lactic acid bacteria, yeasts and molds. Fifty Holstein cows (111±23 d in milk; 2.9±0.9 lactations) were enrolled in a randomized, complete block design study with 1-wk covariate and 6-wk treatment periods. Diets contained 62% DM forage (41% AGS, 21% corn silage) and averaged 15.2% CP, 31.8% NDF, and 26.3% starch. Treatments consisted of untreated AGS (CON) and inoculated AGS (INOC). Cows were group-housed, fed individually 1x/d, milked 3x/d, milk sampled 6x/wk, and CH4 was measured with GreenFeed. Silage and cow data were analyzed using linear models including treatment, week, sampling height, and their interactions as fixed effects. Inoculated AGS had greater lactate and lower acetate concentrations than CON AGS at wk 2 ($P<0.05$) while total VFA concentration was not different between treatments and sampling height. Yeast counts in INOC AGS sampled at 150 cm decreased over time with lower counts at wk 6 ($P<0.05$) compared to CON. Aerobic stability at wk 2, 4, and 6 was improved ($P\leq0.05$) for INOC vs CON AGS at varying sampling heights. Independently of sampling height, ADF was lower in INOC AGS at wk 2 and 6, and aNDFom was lower in INOC AGS from at wk 0, 4, and 6 compared to CON ($P\leq0.05$). In-vitro fiber-digestibility (% NDF) was overall unchanged within treatments. Cows fed INOC AGS had greater DMI resulting in increased energy corrected milk, fat yield ($P=0.05$) and tended to increase true protein yield ($P=0.06$). CH4 production was unaffected by treatment, however, CH4 yield (g/kg DMI) and intensity (g/kg ECM) tended to be reduced ($P<0.07$) in the INOC diet. In this study cows consuming INOC AGS produced more milk as a result of improved silage aerobic stability and fiber composition while methane intensity tended to be reduced.

The effect of alternating concentrate crude protein supplementation on the milk production of spring-calving grazing dairy cows in Ireland

K. M. Mccarthy[1], K. M. Pierce[2], Z. C. Mckay[2], F. J. Mulligan[1]
[1] University College Dublin, School of Veterinary Medicine, Belfield, Dublin 4, Ireland, [2] University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, Ireland

Formulating lower crude protein (CP) concentrate feeds and increasing the dietary fermentable carbohydrate concentration is an effective means of reducing nitrogen (N) excretion from grazing dairy cows. The EU and Ireland have committed to climate neutrality by 2050, requiring a greater use of locally sourced feed ingredients with a lower carbon footprint, such as barley, oats and faba beans. In temperate grazing dairy systems, low CP concentrate supplementation in spring and autumn could potentially restrict milk production as grazing conditions are variable and grass silage is included in the diet. Native protein sources, such as faba beans, which are lower in RUP and AA, may exacerbate this. During these periods, including higher quality protein in the diet, such as SBM, may better support milk production. The objective of this experiment was to investigate 1) the effect of alternating concentrate CP supplementation strategies (CS) and 2) the effect of increasing dietary CP during periods of reduced grazed grass availability, on the milk production of spring-calving grazing dairy cows. Forty multiparous, spring-calving Holstein Friesian dairy cows were randomly assigned to one of two CS strategies for 39 weeks; 1) a 14 % CP concentrate (C14) formulated using barley, oats and faba beans or 2) an 18 % CP concentrate (C14S; C14 + 10 % SBM) in spring and autumn, and C14 during the main grazing season. Cows were 14 DIM when assigned to treatments. Cows were fed C14 or C14S from February for 6 weeks (P1) before being offered C14 during the main grazing season (27 weeks; P2), and returning to C14 or C14S from October until dry-off began (6 weeks; P3). Cows were offered a basal diet of perennial ryegrass (Lolium perenne) and rotationally grazed as one herd during the experiment. Grass silage was fed at an open feed face when required (125 g/kg DM CP, 462 g/kg DM NDF, predicted UFL = 0.87). Pre-grazing grass and grass silage samples were collected weekly. Mean pre-grazing pasture mass was 1398 kg DM/ha (± 394kg DM/ha). Milk yield was recorded daily and milk composition recorded weekly. Data were assessed for normality and analysed using the mixed procedure in SAS. Cumulative milk yield and milk solids yield were unaffected by CS strategy. Daily milk yield during the experiment was 26.9 kg/d and 26.2 kg/d for C14 and C14S respectively. Daily milk solids (MS; fat kg + protein kg) tended to be lower for C14S (- 0.08 kg/d; P = 0.082). In period 1, cows offered C14S had a significantly lower daily milk yield (- 1.2 kg/d; P = 0.031), energy-corrected milk yield (- 1.8 kg/d; P = 0.007) and MS yield (- 0.13; P = 0.006) than those offered C14. Milk production was similar between CS in period 2 and period 3. Alternating CS strategy via increased concentrate CP in the spring and autumn, coinciding with increasing proportions of grass silage in the diet, did not enhance milk production. Instead, cows offered C14S produced significantly less milk in spring, potentially due to an over-supply of RUP relative to requirements. Forage quality in this experiment was high, and this may have resulted in a greater dietary N supply than expected, impacting the results reported. This experiment shows that in high-quality temperate grazing systems, lower CP supplements (14 %) using native ingredients can support milk production as effectively as higher CP concentrates, potentially improving the N efficiency and reducing the carbon footprint of temperate dairy systems.

Effect of partial mixed ration allocation and pellet allocation in the automated milking system on performance of lactating Holstein cows

S. C. Donde[1], T. J. Devries[2], G. B. Penner[1]
[1] University of Saskatchewan, Animal and Poultry Science, 51 Campus Drive, S7N5A8 Saskatoon, Canada, [2] University of Guelph, Department of Animal Biosciences, 553 Gordon St #501, N1G 2W1 Guelph, Canada

Studies evaluating feeding management of cows in automated milking systems (AMS) largely focus on AMS pellet feeding strategies, despite the partial mixed ration (PMR) providing the greatest quantity of nutrients and influencing cow movement throughout the barn. This study evaluated whether feed allowance of the PMR interacts with amount of pellet provided in the AMS on dry matter intake (DMI), feeding and milking behaviour, reticular pH, and milk and milk component yields for Holstein cows. Eight Holstein cows in early lactation (68 ± 24 days in milk) were used in a replicated 4×4 Latin square design with a 2×2 factorial treatment arrangement. Treatments included PMR management where cows were provided PMR for ad libitum (AL; refusals equating to 10% as fed of the weight of the PMR offered) or slick bunk PMR management (SB; <3% refusals) in combination with a low (LA) or high (HA; 2 vs. 4 kg/d DM, respectively) pellet allocation in the AMS. Periods included 14-d for dietary adaptation and 7 d for data and sample collection. Cows were housed in a free-stall barn with individual feed bunks, allowing for measurement of feeding behaviour and intake in a feed-first guided-flow traffic AMS design layout. The AMS feed trough was modified to enable measurement of AMS pellet intake. Data were analyzed including the fixed effects of square, period, PMR management, pellet allocation in the AMS, and the interaction between bunk management and pellet allocation. Cow nested within square was the random effect. Providing the PMR AL tended (P = 0.08) to increase PMR intake (2.4 kg/d) over SB, while the pellet allocation did not affect PMR intake. Although HA cows refused 0.50 kg/d more pellet in the AMS than LA cows (P<0.01), HA cows had greater AMS pellet intake than LA cows (3.7 vs. 1.5 DM kg/d, respectively; P<0.01). Consequently, feeding PMR AL tended to increase total DMI over those fed PMR for SB management (31.3 vs. 29.0 kg/d, respectively; P = 0.08), and cows fed HA tended to have greater DMI than cows fed LA (31.3 vs. 29.0 kg/d, respectively; P = 0.09). Although no effect of treatment was detected for mean reticular pH, cows fed PMR for SB with the HA had the lowest minimum reticular pH (PMR ×AMS; P=0.02) relative to all other treatments. Likewise, cows fed PMR for SB with HA had the greatest duration and area of reticular pH <5.8 (PMR ×AMS; P<0.01) relative to the other treatments. While no effect of PMR management on milk yield was detected, yield tended to be greater for cows fed the HA when compared to the LA (61.9 vs. 58.7 kg/d; P=0.07). No treatment effect was detected for milk fat yield or concentration, but the de novo fatty acid (P=0.05) concentration tended to be greater for cows provided AL than SB PMR management (25.0 vs. 24.1% of fatty acids). Moreover, cows provided AL PMR had a greater concentration of mixed fatty acids than cows fed PMR for SB management (38.5 vs. 37.8% of fatty acids; P=0.04). These results indicate that for high yielding Holstein cows in early lactation, limiting PMR availability may increase risk for low ruminal pH when fed higher pellet allocations in the AMS. Moreover, feeding AL PMR may increase DMI and de novo and mixed fatty acids, while feeding more pellet in the AMS may also increase DMI and milk yield without affecting fat yield.

Effects of barley grain processing methods and dietary starch level on lactating dairy cows dry matter intake, ruminal fermentation, milk and milk component yields

T. Gondo[1], G. Penner[1], T. Mutsvangwa[1], G. Ribeiro[1]
[1] University of Saskatchewan, Animal and Poultry Science, 51 Campus Dr, S7N 5A8 Saskatoon, Canada

Barley grain is a common cereal grain used in Western Canada, Australia, and parts of Europe. As barley starch is rapidly degradable in the rumen, recommendations for barley grain processing focus on avoiding excessive production of fine particles. However, the impact of processing method may be more important when diets contain high starch than low starch concentrations. This study investigated whether processing method (ground (GB) vs. dry-rolled barley (DB)) and the dietary starch concentration (25% (LS) vs. 32% DM (HS)) affected dry matter intake (DMI), ruminal fermentation, milk yield, and milk composition for lactating Holstein cows. Eight cows (713 ± 80 kg BW, 162 ± 56 days in milk) were used in a 4×4 Latin rectangle design with a 2×2 factorial arrangement of treatments. Periods lasted 25-d and included 18 days for dietary adaptation and 7 days for data and sample collection. Data were analyzed using the mixed model of SAS including processing method, dietary starch, and their 2-way interaction as well as period included as fixed effects. Cow nested within square was included as a random effect. Dry matter intake was not affected by the processing method and starch level. Cows fed HS sorted against fine particles ($P < 0.01$) and sorted for long particles (19 mm sieve, $P < 0.01$) relative to those fed LS but there was no effect of barley grain processing method on feed sorting. Mean ruminal pH was greater for cows fed GB than those fed DB (6.23 vs. 5.98; $P = 0.03$). The duration that ruminal pH was <5.8 was greater for HS than LS (488 vs. 235 min/d; $P = 0.03$), and greater for DB than GB (510 vs. 213 min/d; $P = 0.02$). The concentration of total short-chain fatty acids and the molar proportions of individual fatty acids were not affected by treatment. Milk yield was not affected averaging 36.3 kg/d. Likewise, the concentration of protein and lactose were not affected by treatment. Milk fat concentration was reduced by nearly 0.5 kg/d (4.05 vs. 4.54%; $P = 0.03$) with HS than LS, but milk fat yield did not differ averaging 1.51 kg/d. Despite the reduction in milk fat concentration for HS than LS, there were no differences for the proportion of fatty acids arising from de novo, mixed, or preformed fatty acids. In conclusion, other than mean pH, the processing method had little effect on responses of cattle; while feeding HS increased feed sorting, reduced mean ruminal pH, and the concentration of fat in milk.

Dietary carbohydrate fractions as modulators of dry matter intake in high-producing Holstein dairy cows: a meta-analytic approach

U. Serbester[1], P. Y. Bozkaya[1], A. G. Aydoner[1]
[1] Cukurova University, Animal Science, Balcali, 01330 Adana, Turkey

Dietary composition is a primary modulator of voluntary dry matter intake (DMI) in lactating dairy cows, yet the relative contributions of individual carbohydrate fractions remain incompletely characterised across production levels in large meta-analytic datasets. We hypothesised that neutral detergent fibre (NDF) and non-fibre carbohydrates (NFC) are the dominant dietary predictors of DMI, and that their associations with intake would differ across energy-corrected milk (ECM) yield classes. A database of 429 treatment means was assembled from 132 peer-reviewed studies published between 1984 and 2025, comprising 6,827 Holstein cows housed exclusively in freestall systems and fed total mixed (TMR) or partial mixed (PMR) rations. Only studies with completely randomised (CRD) or randomised block (RBD) designs were included; Latin square and crossover experiments were excluded. Treatment means were classified into three ECM classes: Class 1 (<30 kg/d; n = 113), Class 2 (30–40 kg/d; n = 174), and Class 3 (>40 kg/d; n = 142). Pearson correlations and multiple regression analyses were performed to quantify associations between dietary variables (crude protein [CP], NDF, acid detergent fibre [ADF], starch, NFC, and net energy for lactation [NEL]) and observed DMI, with ECM yield class and body weight (BW) as covariates. Data availability varied markedly across fractions: NDF was reported in 407 of 429 treatment means, starch in 232, and NFC in only 143; class-level NFC analyses were based on n = 50, 55, and 38 observations for Classes 1, 2, and 3, respectively, and should be interpreted with caution. Across the full dataset, NFC showed the strongest positive association with DMI (r = +0.39; n = 143), followed by starch (r = +0.26; n = 232), while NDF was the most consistently negative correlate (r = −0.27; n = 407). ADF (r = −0.14), CP (r = +0.10), and NEL (r = −0.03) showed weaker associations. Among animal-level predictors, ECM was the strongest (r = +0.58), followed by BW (r = +0.45), while BCS showed no association (r = +0.004). When stratified by ECM class, the NDF–DMI relationship was inconsistent (Class 1: r = −0.14; Class 2: r = +0.01; Class 3: r = −0.28), indicating that the overall negative relationship is mainly driven by cows at the extremes of the production range. The NFC–DMI association was positive in all classes and numerically strongest in Class 3 (r = +0.57), although the small sample sizes preclude firm conclusions at the class level. Multiple regression with ECM class and BW as covariates confirmed that NFC was a significant independent predictor of DMI (β = +0.20 kg DMI/% NFC; P < 0.001; n = 143), while NDF did not reach significance after adjustment (β = −0.05; P = 0.097; n = 407). These findings indicate that increasing dietary NFC supports higher voluntary DMI across production levels. The lack of an independent NDF effect after covariate adjustment suggests that its apparent negative correlation with DMI is largely mediated by production level and body weight. These results provide a quantitative basis for precision ration formulation aimed at enhancing feed efficiency and resource use in circular dairy systems.

Impact of feeder type on voluntary intake and milk production in lactating dairy cows

Y. Huang[1], S. Hu[1], L. Delaby[1]
[1] INRAE, Institut Agro, UMR Pegase, 35590 Saint-Gilles, France

The use of automated weighing feeders enables the continuous measurement of individual feed intake by recording the amount consumed at each visit, without restricting animals to a fixed individual feeder. While facilitating feed management and intake measurements, these systems may also alter feeding conditions and voluntary feed intake. This study compared voluntary intake and production performance of lactating dairy cows fed using shared automated weighing feeders or fixed individual feeders. Forty mid-lactation dairy cows were allocated to 4 balanced groups according to stage of lactation, parity, and intake and performance measured during a reference period. Cows were subjected to 2 feeding systems (weighing vs fixed individual feeders) while receiving the same diet composed of 65% corn silage and 35% concentrate, following a double cross-over design with four 2-week periods. The use of automated weighing feeders resulted in a higher dry matter intake (DMI; 27.0 vs. 25.3 kg/d; $P < 0.001$), whereas drinking water consumption at the trough was slightly lower (84.0 vs. 86.7 L/d; $P < 0.05$) compared with fixed individual feeders. Consequently, milk yield (33.0 vs. 32.0 kg/d; $P < 0.001$), milk fat content (41.5 vs. 40.8 g/kg; $P < 0.05$), milk protein content (33.6 vs. 33.2 g/kg; $P < 0.001$), and energy-corrected milk yield (34.2 vs. 32.6 kg/d; $P < 0.001$) were also higher. The higher intake observed with automated weighing feeders may be partly explained by greater freedom of access to the feed. In line with this hypothesis, the inter-daily variability of dry matter intake was higher with automated weighing feeders (2.32 vs. 1.54 kg; $P < 0.001$). In conclusion, automated weighing feeders increased voluntary feed intake and milk production in lactating dairy cows. These first results highlight the need to reconsider the evaluation of ad libitum DMI and the associated intake prediction models.

Quantifying energy expenditure in lactating dairy goats using the doubly labelled water method under pasture and indoor housing conditions

A. Haus[1], C. Blaschka[1], J. R. Speakman[3,4], A. Patt[2], J. Hummel[1], A. Riek[2]
[1] University of Göttingen, Department of Animal Sciences, Kellnerweg 6, 37077 Göttingen, Germany, [2] Friedrich-Loeffler-Institut, Institute of Animal Welfare and Animal Husbandry, Dörnbergstr. 25/27, 29223 Celle, Germany, [3] University of Aberdeen, Institute of Biological and Environmental Sciences, King's College, AB24 3FX Aberdeen, United Kingdom, [4] State Key Laboratory of Molecular Developmental Biology, Institute of Genetics and Developmental Biology, 1 West Beichen Road, 100101 Beijing, China

Pasture-based systems (PBS) are widely regarded as beneficial for the welfare of ruminants, including goats. However, PBS may also elevate the risk of a negative energy balance in lactating dairy goats due to increased locomotion and higher maintenance energy requirements. The present study aimed to compare the daily energy expenditure (DEE) of dairy goats at peak lactation under a PBS with that of indoor-housed (IND) goats. In addition, the study evaluated whether measured DEE corresponds with established recommendations for the energy supply of lactating dairy goats. Eleven primiparous dairy goats (body mass: 43 ± 3.9 kg) were assigned to the two housing systems IND (n = 6) and PBS (n = 5). At the start of the experiment, goats were in early lactation (days in milk: 17 ± 10 days). Milk yield was recorded daily, and milk samples were collected twice per week. Daily energy expenditure was quantified using the doubly labelled water (DLW) method following established protocols over the course of seven days. The DLW method estimates daily energy expenditure in free-living animals by quantifying CO_2 production from the differential elimination rates of hydrogen and oxygen isotopes after administration of isotopically labelled water. This approach provides an integrated measure of whole-body energy expenditure under standard husbandry conditions. Milk samples were analyzed for gross energy content by bomb calorimetry. Because the DLW method captures energy expenditure for milk synthesis but does not account for the energy exported in milk, individual milk energy output was calculated and added to DEE to obtain the total energy balance. Group comparisons were performed using linear models with contrasts to account for unbalanced data. When assessing differences in total energy balance or calculated energy requirements between housing systems, body mass was included as a covariate. Statistical significance of housing system effects was evaluated using Type II ANOVA. Mean daily milk yield did not differ between housing systems averaging 2.2 ± 0.4 kg in IND and 2.3 ± 0.1 kg in PBS. Body mass was also comparable between both groups (IND: 43 ± 4.0 kg; PBS: 43 ± 3.8 kg). Total energy balance, i.e. DEE plus milk energy output was significantly higher in PBS (17.2 ± 1.3 MJ day^{-1}) compared with IND goats (15.9 ± 1.7 MJ day^{-1}, $p < 0.05$). Likewise, calculated energy requirements were higher in PBS (17.3 ± 0.9 MJ ME day^{-1}) than in IND goats (15.4 ± 1.7 MJ ME day^{-1}, $p < 0.05$). The ratio of measured total energy balance to calculated energy requirements did not differ between housing systems (IND: 104 ± 8%, PBS: 99 ± 9%), indicating that measured energy expenditure was only 4% higher than predicted in IND goats and only 1% lower in PBS goats, suggesting close agreement between actual and expected energy use across systems. Although milk yield and body mass did not differ between housing systems, total energy balance was higher in PBS goats due to higher milk energy contents. Furthermore, the comparable ratio of total energy balance to calculated energy requirements between both groups suggests that current energy recommendations already account for some of the system-specific costs of PBS.

Partitioning of vitamin E in lactating dairy cows at two levels of vitamin supplementation

M. Simoni[1], S. Pintossi[1], F. Righi[1]
[1] University of Parma, Department of Veterinary Science, Strada del Taglio, 10, 43126 Parma, Italy

Vitamin E (VE) is a key lipid-soluble antioxidant involved in protecting biological membranes from oxidative damage and supporting immune functions. Supra-nutritional levels improved immune responses in some instances. We hypothesized that VE overfeeding could play an important role especially when heat stress occurs. The objective of this study was to evaluate the partitioning of VE to milk following the administration of two levels of VE in two seasons. Fourty-six multiparous Holstein cows (BW 750±78.8 kg) of a commercial dairy herd located in the Parmigiano Reggiano cheese-production area (N° of cows 883±48; milk yield 36±1.5 kg/d) were selected 7 days after calving, including 22 and 24 cows that calved during the winter (October to November) and summer (May to July) seasons, respectively. Cows assigned to two pens, balanced for parity and date of calving, received 2 hay-based total mixed ration (-TMR- aNDF 36 %DM, starch 27 %DM, CP 14.4 %DM, EE 2.6 %DM) supplemented with high (HVE; 8000 mg/d) or low (LVE; 1600 mg/d) doses of VE. Animals were observed from 7 to 150 days in milk (DIM). The girth circumference was measured individually at the beginning of the trial to estimate the BW and metabolic BW. Feed intake was measured weekly on a pen base by difference between the amount of feed delivered and orts. Meanwhile, the TMR of each group was sampled and chemically analyzed. Plasma samples were collected from the coccygeal vein at 7, 20, 60 and 150 DIM, and analyzed for the metabolic profile and VE content. Milk yield was recorded, and milk samples were collected individually 3 times per season during the milk samplings performed by the breeder association. Milk quality was determined by MilkoscanTM while VE content was determined using an iCheck fluorometer–spectrophotometer (iCheck Vitamin E; BioAnalyt GmbH, Teltow, Germany). Data were statistically analyzed by generalized linear models using SPSS software (IBM SPSS Statistics for Windows, Version 29.0; IBM Corp., Armonk, NY). An increase in the DMI was observed in the summer season in the HVE vs LVE group (29.2 vs 28.0; p=0.027), although metabolic profile, milk yield and quality were similar between groups. The highest daily VE secretion in milk was observed in the HVE group during the winter season (222 and 146, 133 and 105 mg/d, for HVE and LVE in winter season, HVE and LVE in summer season, respectively), while no differences were found in the LVE group between seasons. The plasmatic content of VE was higher in the HVE group (p<0.001), and especially in the winter season reaching 382 mg/d. A higher proportion of VE partitioned to the milk on the VE assumed was observed for the LVE group (p<0.001) especially in the winter season (7.71 vs 5.44 for winter vs summer; p<0.001), indicating a possible better absorption efficiency. The retention of VE was always higher in the HVE group (p<0.001), with the highest observed in the summer season (9109 vs 8981 mg/d; p=0.003). Similar results were found considering the proportion of VE retained on the assumed (93.7 vs 84.78 for HVE vs LVE in winter season, p<0.001; and 95.6 vs 89.06 for HVE vs LVE in the summer season, p<0.001).

Effect of whey or skim milk as the main protein source in milk replacer on growth performance in dairy calves

P. Górka[1,2], W. Budziński[3]
[1] University of Agriculture in Krakow, Department of Animal Nutrition and Fisheries, al. Mickiewicza 24/28, 30-059 Krakow, Poland, [2] National Research Institute of Animal Production, Department of Animal Nutrition and Feed Science, ul. Jurajska 44, Aleksandrowice, 32-084 Morawica, Poland, [3] Polmass S.A., ul. Grunwaldzka 287, 85-438 Bydgoszcz, Poland

Both whey and skim milk are considered valuable sources of protein in calf milk replacer (MR). However, whether MR containing protein derived from whey or skim milk should be preferred in the nutrition of dairy calves is still debatable. Thus, this study aimed to determine the impact of whey-based and skim milk-based MR on the growth performance of dairy calves. Ninety male and female Holstein calves were randomly allocated at day 10 of age to one of three groups (n = 30/group) and fed: 1) whey-based MR that contained no skim milk (G0); 2) MR that contained 25% skim milk (G25); and 3) MR that contained 50% skim milk (G50). In G0 and G25, whey protein concentrate was used as the main ingredient. Groups were balanced for the number of bull and heifer calves as well as calves born from primi- and multiparous cows. Prior to allocation to the study, calves were fed first colostrum (4 L) and subsequently a mixture of surplus colostrum and raw milk. Growth performance and health parameters of calves were monitored from 10 until 60 days of age. Experimental MRs were formulated to contain a similar concentration of crude protein (22% as is), crude fat (20%), Lys (2.3%), Met (0.75%), Thr (1.7%) and Trp (0.44%). From the first day of the study, the calves were fed 7.5 L daily of MR in three feedings (2.5 L/feeding), which was prepared to ensure 160 g of MR powder in 1 L of milk (in total 1200 g/day/calf). Starter mixture was offered ad libitum from the first day of the study. Feces were scored daily using a 4-point scale and all medical treatments were recorded. Passive immunity was determined between day 2 and 3 of age. Data were analyzed using the MIXED procedure in SAS. The statistical model included the effects of experimental group, calf sex, maternal status (primiparous or multiparous), and the interaction between them as classifying variables. Because the interactions were non-significant, they were removed from the model. When justified, initial body weight was included in the model as a covariate. Passive immunity and initial body weight (BW) did not differ between groups ($P \geq 0.24$). Cumulative MR and starter intake did not differ between groups ($P \geq 0.28$). Final BW was higher for G25 compared to G50 (83 vs. 79.8 kg; $P \leq 0.05$) but did not differ between G0 and G50 (81.9 kg) or between G0 and G25 ($P > 0.05$). Similarly, average daily gain and feed efficiency (gain-to-feed) were higher for G25 compared to G50 ($P \leq 0.05$) but did not differ between G0 and G25 or between G0 and G50 ($P > 0.05$). Fecal score and number of medical treatments did not differ between groups ($P \geq 0.09$). In the current study, the rearing outcomes of calves fed MR containing only whey protein did not differ from those fed MR containing skimmed milk powder. When skim milk powder inclusion in MR increased from 25% to 50%, this resulted in a lower final body weight by 8.5%. Using a milk replacer containing whey and a moderate proportion of skimmed milk powder (25%) resulted in the best growth performance of calves and the highest feed efficiency.

Improving milk yield while reducing diet carbon footprint in European lactating dairy cows.

T. Aubineau[1], L. Drouet[1], T. Legot[1], F. Bedel[1]
[1] AVRIL, Mixscience, Avenue de Ker Lann, 35170 BRUZ, France

Soybean meal (SBM) is a major protein source in dairy cow diets worldwide, due to its high protein content and competitive price. Though, SBM raises environmental issues in European farming because of its high carbon footprint. Replacing SBM by European protein sources implies amino-acid balancing to maintain zootechnical performance. The objective of this trial was to assess the effects of SBM removal combined with essential oils, methionine and lysine supplementation in the diet of lactating dairy cows on milk yield (MY) and energy corrected milk (ECM) persistence. The trial was conducted in the experimental dairy farm of Agroevolution (France), composed of 105 lactating cows producing on average 38 Kg of milk per day (milk protein content = 34.5 g/kg, milk fat content = 44.5 g/kg), and fed a partial mixed ration based on corn silage, grass silage and concentrates. A total of 69 cows after peak lactation were selected and allocated to three groups of 23 lactating cows each, blocked by parity (15 multiparous and 8 primiparous cows per group), days in milk, and milk yield the week before the trial. Following a two-weeks adaptation period with all cows receiving a CONTROL diet, the cows entered a seven-weeks experimental period. The CONTROL group was fed the CONTROL diet, including 2.5 Kg of SBM. MET and MET-LYS groups were fed diets without SBM, replaced by rapeseed meal, rapeseed expeller and corn DDGS, and supplemented with essential oils to stimulate microbial protein synthesis (VALOPRO ACTION ®, 20 g/cow/day). All three diets were formulated to get the same net energy and crude protein content (1.6 Mcal/kg DM and 163 g/kg DM), but differed in methionine and lysine content due to rumen bypass methionine and lysine supplementation (digestible methionine intake of 63, 76 and 76 g/cow/day and digestible lysine intake of 191, 190 and 203 g/cow/day, in respectively CONTROL, MET and MET-LYS diets; NDS Professional ®). Individual feed intake and milk yield were recorded daily, while milk protein and fat contents were analyzed weekly. MY (resp. ECM) persistence was assessed by comparing the slopes of MY (resp. ECM) over time using a multivariate mixed model including parity, day (resp. week), group, group:day (resp. week), parity:day (resp. week), and a random effect, depending on cow, on intercept and slope (R software, nlme package). At the start of the experimental period, cows averaged 204 ± 105, 199 ± 83, and 182 ± 77 days in milk (DIM) in the CONTROL, MET and MET-LYS groups, respectively. MY at intercept did not differ among groups (39.8 ± 1.7, 37.5 ± 1.4 and 38.9 ± 1.6 kg, respectively in CONTROL, MET and MET-LYS groups, P=0.560), and was higher in multiparous than in primiparous cows (+4.8 kg/d, P=0.001). MY persistence was improved in both MET and MET-LYS groups, compared to the CONTROL group (+ 0.03 and + 0.06 kg/day, respectively, P<0.001), and was higher in primiparous cows than in multiparous cows (+0.03 kg/day, P<0.001). ECM at intercept did not differ among groups (39.9 ± 1.5, 38.5 ± 1.3 and 41.5 ± 1.4 kg in CONTROL, MET and MET-LYS groups, respectively, P=0.249), and was higher in multiparous than in primiparous cows (+4.7 kg, P<0.001). ECM persistence did not differ between groups (P=0.888) nor parity (P=0.238). Carbon footprints of MET and MET-LYS diets were 2.3 and 2.2 kg/cow/day lower when compared to CONTROL diet (-17 and -16%, respectively; Agribalyse® database). This study highlights the positive effects of methionine, lysine and essential oils supplementation on MY persistence when replacing soybean meal by local protein sources in lactating dairy cows' diet in a European context. These results support the hypothesis that replacing SBM in dairy cow diet may be sustainable in European dairy farms.

Environmental strategies and milk production in European dairy basins : focus on the climate smart french initiative

J. Andurand[1], E. Castellan[1], J. Guillemin[1]
[1] IDELE, Environment, Site de Monvoisin, 35652 Le Rheu, France

Is the dairy dynamic in major production areas influenced by environmental regulations ? A review of the main production zones reveals a diversity of contexts and also variability depending on the issues at stake: from non-binding voluntary incentive schemes in France to production constraints in the Netherlands, or economic constraints via a tax in Denmark for example.In a first approach we will present the characteristics and environmental results of major dairy production countries in and outside Europe regarding the main environmental indicators : greenhouse gas emissions, water quality, air quality and biodiversity. The dairy basins studied will be USA (9 millions of head), New Zealand (4.6 millions of head), France (3,2 millions of head), Ireland (1,5 millions of head), Netherlands (1,5 millions of head), Denmark (0,5 millions of head) with for example GHG gross emissions from 0,77 to 1,3 kg eCO2/ liter of milk. The results and regulation analysis will be presented in this first part, in particular from following projects Dairy-4-Future, Interreg Atlantic Area (2018-2022); ClieN-Farms H2020 (2022-2026) Climate-neutral systems; PATHWAYS H2020 (2021-2027) Pathways for transitions to sustainability in livestock farming and food systems; Carbon farming Life Europe (2021-2027) Low-carbon approaches and carbon credits. In a second part we will analyse how environmental regulations and targets of major agro industries are affecting production and ambitions of the major dairy basins. Policys framework will be detailed from Nitrate and Habitats Directives to the global methane pledge and how they transcript for farming sector in the various dairy countries. Strategies of large dairy groups will be presented with objectives and resources deployed to encourage changes in practices. During the third part, a testimony of French dairy sector initiatives will be presented: research and tools/methods developed, advisory system, practices selected and implementation on dairy farms, incentives, barriers and farmers feedback, lessons learned and results for the dairy sector. The carbon footprint of milk in France has significantly decreased over recent decades. Between 1990 and 2010, emissions per litre of milk dropped by about 20–24%, reflecting major efficiency gains in dairy farming . More recently, progress has slowed, with about a 6-7 % reduction between 2016 and 2021 . Overall, the sector has already achieved substantial reductions but now faces diminishing returns. Several solutions have driven this improvement, with more 35,000 of farm assessment with CAP2ER LCA tool. Farmers have optimized herd management, increasing productivity per cow and thus reducing emissions per litre. Feed changes, such as replacing imported soy with local crops, have also lowered emissions. Better manure management and spreading techniques have reduced methane and nitrous oxide emissions. In addition, carbon storage in grasslands and improved energy efficiency in processing and transport have contributed. These combined actions explain the steady but now slower decline in the carbon footprint of milk in France.

Structural consolidation and sustainability priorities in the Polish dairy sector (2004–2026): lessons from a fast-transforming EU dairy region

A. Cieślak[1], J. Łagoda[1], J. Sznajder[1], J. Szczesny[1], S. Olorunlowu[1], M. Szumacher-Strabel[1]
[1] Poznan University of Life Sciences, Department of Animal Nutrition, Wołynska 33, 60-637 Poznan, Poland

Poland is one of the largest milk producers in the European Union, with production increasingly concentrated in three major dairy regions—Podlasie, Mazovia, and Greater Poland—which together account for more than 50% of the national dairy cow population. Over the last two decades, the Polish dairy sector has undergone profound structural transformation and intensification. The number of dairy herds declined from approximately 751,000 in 2004 to fewer than 236,000 in 2022, with a further decrease between 2022 and 2023 (from 180,800 to 173,300 farms keeping cows). At the same time, average herd size increased from 3.9 cows in 2005 to more than 13 in 2020. Total milk production rose by about 60% despite an estimated 21% reduction in cow numbers, reflecting major gains in productivity, technological uptake, and management intensity. By June 2024, stocking density had reached 14.6 dairy cows per 100 ha of agricultural land, underlining the growing importance of nutrient cycling and manure management at both farm and regional levels. Nevertheless, assessing the structure of Polish dairy farming remains challenging: 2020 data indicate that medium-sized farms with 20–99 dairy cows accounted for about 21% of holdings, whereas large farms with more than 100 cows represented only about 1%. This case study shows how a consolidating dairy region can simultaneously increase output and retain scope for further development. The Polish dairy sector still has considerable growth potential, driven by ongoing productivity gains, investment in herd management and forage systems, and strong regional specialisation. Farms are also increasingly adopting automated milking systems and on-farm monitoring technologies, including milking robots, sensor-based health and production control, and precision data platforms. These innovations enhance management capacity, enable more targeted resource use, and may help lower environmental pressure through modern production technologies. However, future development will be shaped by two interrelated pressures: growing competition from external markets, including the possible effects of expanded trade with Mercosur countries, and the need to reduce methane emission intensity and nitrogen losses to water and air in response to increasingly stringent EU climate and environmental requirements. Against this background, we identify priority areas and transferable solutions aligned with the Sustainable Development Goals. These include precision feeding and forage-quality optimisation to reduce enteric methane emissions per kilogram of milk; whole-farm nutrient accounting supported by decision-support tools; innovations in manure handling, such as separation, covered storage, anaerobic digestion, and other context-specific mitigation options; and robust digital monitoring and reporting systems to enable credible low-carbon product claims and participation in emerging incentive schemes, including carbon-related mechanisms. Strengthening advisory services and cooperative models will be essential to accelerate uptake while preserving economic viability across farms of different sizes. In Poland, such advisory support is provided mainly by private-sector consultants associated with feed companies and by advisors linked to organisations representing cattle breeders and milk producers, rather than exclusively through state-organised extension services. Taken together, these developments provide a practical pathway for combining competitiveness, environmental performance, and resilience in a rapidly transforming dairy region.

Developments in the dairy sector in the Baltic States region: from recent trends to medium-term outlook

S. Zeverte-Rivza[1], A. Rizojeva-Silava[1]
[1] Latvia University of Life Sciences and Technologies, Faculty of Economics and Social Development, Svetes street 18, LV3001 Jelgava, Latvia

The dairy sector in the Baltic States plays a strategically important role in regional food systems, rural employment, and export performance, while operating within the broader framework of the European dairy market. The sector is increasingly shaped by structural consolidation, technological modernization, environmental requirements, and geopolitical uncertainty. To position the Baltic region within the wider European context, the study first applies factor analysis and cluster analysis using Eurostat data grouped into three categories: dairy production capacity, market dynamics, and economic–demographic indicators. The results confirm substantial structural differences across Europe. Central and Western European countries exhibit higher efficiency and export orientation, whereas Eastern and Southern European regions, including parts of the Baltic area, face structural constraints and relatively lower competitiveness. These findings highlight the need for region-specific development strategies. Building on this regional perspective, the study conducts an in-depth medium-term assessment of dairy sector development prospects to 2032 using an integrated modelling framework that combines the AGMEMOD partial equilibrium model with the TOPSIS multi-criteria decision-making method. The AGMEMOD model was recalibrated using updated national data for 2015–2023, significantly improving its empirical accuracy: the projected milk yield for 2024 (8,124 kg per cow) closely approximates the actual statistical value (8,239 kg). In AGMEMOD two scenarios were developed: (A) Targeted and intensive farm modernization, and (A2) Limited farm modernization under conditions of policy uncertainty. Scenario A is defined by the integration of productivity-enhancing factors, taking into account the impact of such factors as the genetic progress, modern technologies i.e. precision feeding, robotic milking etc. These factors are not included directly, but as an estimation of their impact on the productivity of cows. Scenario A results in a 4.9% higher average milk yield compared to the baseline, while maintaining stable overall production without herd expansion, reflecting productivity-driven growth. In contrast, Scenario A2 shows slower productivity gains and increased vulnerability to cost and regulatory pressures. The TOPSIS evaluation identifies Scenario A as the most favourable alternative (proximity coefficient = 0.980), demonstrating that gradual and structured technological integration – particularly through precision herd management and digital monitoring systems – enhances sectoral resilience and competitiveness. Overall, the findings suggest that sustained technological modernization, supported by adaptive and flexible policy instruments, is critical for maintaining productivity and market performance in the Baltic dairy sector. And the integrated AGMEMOD-TOPSIS framework offers a robust methodological tool for evidence-based policy evaluation and strategic planning, contributing to the broader scientific discourse on regional dairy development pathways within the European and global context.

Recent Developments in Dairy Farming in Slovenia and Croatia

M. Klopčič[1], M. Špehar[2]
[1] UL, Biotechnical Faculty, Department of Animal Science, Groblje 3, 1230 Domžale, Slovenia, [2] Croatian Agency for Agriculture and Food, Svetošimunska Cesta 25, 10000 Zagreb, Croatia

Slovenia and Croatia entered the EU in, respectively, 2004 and 2013. The developments in Slovenia are very much based on the principle in the former Yugoslavian Republic that private farmers were allowed to have a max of 10 ha agricultural land. Also, a high share of agricultural land is owned by people who moved to the city, which results in a carpet of many parcels. For that reason, till to-day, most dairy cows (about 70 %) are still held inside for efficiency reasons, although grazing is encouraged. The family farm is the standard with most common 20 to 70 cows. All of family supports the farm. Statistical data show that the correlation between family income and size of farm is weak. Especially the management of farm determines the income. Milk production level of the 80% recorded cows in Slovenia is 7,674 kg/year with 4.06 % fat and 3.41 % protein. Of the total cow herd, 39% is Holstein-Friesian, 33% Simmental, 7.6% Brown Swiss and 20.4% are crossings. In Croatia, the proportion of medium sized herds (from 10 to 30 cows) is dominant (39.40%), while relatively large farms with more than 100 cows represent around 13% of all dairy farms. The Simmental breed is prevalent in milk production and is reared mostly on family farms. Holstein-Friesian cows represent the second most important cattle population and are kept mainly on enterprises specialized in milk production. In Simmental breed, milk production of recorded herds is 7,157 kg/year with 4.10 % fat and 3.50 % protein. Holstein-Friesian breed has 8,838 kg/year with 4.20 % fat and 3.50 % protein. Milk prices tend to be a bit higher in Croatia than in Slovenia, where the milk is mainly sold and transported to Italian companies. For comparison, the prices are in between the Netherlands (high) and Lithuania (low). Focus in Slovenia is on special products and direct sales, employing family labour. About 10 % of the dairy farms engage in those on-farm activities. Because of large Nature 2000 areas and less favourable areas, the environment, especially nitrogen application, has been for longer time a focus field. Also, because in the valleys with fertile soils, dairy farming has become quite intensive. Mechanization and automatization is popular. In Croatia, emphasis is more on efficiency and farm size, imitating Western European countries. In both Croatia and Slovenia, societal discussions about the animal's sectors are rather intense, mainly from the viewpoint of animal welfare (tie-stalls, outside conditions, calf rearing). Case farms in both Croatia and Slovenia will be presented showing strategies and future aspirations of the respective farmers/ families.

The Ukrainian Meat and Dairy Sector and Agricultural Science under Wartime Conditions: Current Challenges, Adaptation Mechanisms and Development Prospects

I. Ivanytskyi[1]
[1] *Institute of Animal Biology, Laboratory of Reproduction Biotechnology, 38 Vasyl Stus St., 79034 Lviv, Ukraine*

Livestock production represents a strategic component of food security and rural economic stability in Ukraine. Since the onset of the full-scale war in 2022, the Ukrainian meat and dairy sectors have operated under severe disruption affecting farm infrastructure, supply chains, labour availability, veterinary services, and access to domestic and international markets. These challenges have created a highly unstable production environment and have significantly undermined the sustainability of livestock enterprises. This contribution analyses the main challenges currently affecting livestock production systems in Ukraine and identifies the key adaptation mechanisms implemented by producers and agricultural research institutions to maintain production continuity under wartime conditions. Special attention is paid to the role of scientific support and knowledge transfer in strengthening sectoral resilience. The analysis considers implications for food security and continuity across broader livestock supply chains. Wartime conditions have substantially affected the operational management of livestock farms. Disruptions in feed supply, electricity shortages, logistical constraints, and rising production costs have negatively influenced herd productivity, reproductive efficiency, and animal health management. Dairy cattle and pig production systems, two of the most important branches of Ukrainian livestock production, have been particularly exposed to these pressures. At the same time, volatility in milk and meat prices, reduced investment capacity, and uncertainty regarding market access have created additional structural risks for the long-term development of the sector. Despite these constraints, Ukrainian livestock producers have demonstrated considerable adaptive capacity. Farms have introduced a range of management strategies aimed at maintaining productivity and reducing risks, including the optimisation of feeding systems, reinforcement of biosecurity measures, improved herd health monitoring, and more efficient reproductive management. Increased collaboration among farmers, veterinarians, and research institutions has become an essential element of crisis response and knowledge exchange. Agricultural science plays a key role in supporting the sector under these conditions. Ukrainian research institutions continue to develop applied solutions in the fields of reproductive biotechnology, disease control, animal genetics, and sustainable livestock production. In addition, strengthened international scientific collaboration and the use of digital communication platforms have made it possible to continue research and advisory activities despite wartime limitations. The Ukrainian experience highlights the importance of scientific support, adaptive farm management, and international cooperation in sustaining livestock production systems during periods of severe socio-economic disruption. The lessons derived from this experience may contribute to the development of more resilient animal production systems and provide valuable insights for the European livestock sector in the face of growing global uncertainty.

Description of risk factors and management practices associated to mastitis and milk quality on organic dairy farms across the USA

C. Niño De Guzmán[1], L. Prada[2], S. Bellinzoni[2], P. Muñoz[3], C. Hernandez[3], C. Ibarguren[3], R. Weng[3], P. De Caso[5], Q. Kolar[4], V. Cabrera[5], B. Heins[6], R. Lynch[4], E. Miller-Cushon[1], G. Schuenemann[2], P. Pinedo[3], A. De Vries[1]

[1] University of Florida, Department of Animal Sciences, 2250 Shealy Dr., 32608 Gainesville FL, United States, [2] The Ohio State University, Department of Veterinary Preventive Medicine, 1920 Coffey Rd., 43210 Columbus OH, United States, [3] Colorado State University, Department of Animal Sciences, 350 W Pitkin St., 80521 Fort Collins CO, United States, [4] Cornell University, Department of Animal Sciences, 149 Morrison Hall, 507 Tower Rd., 14850 Ithaca NY, United States, [5] University of Winsconsin-Madison, Department of Animal and Dairy Sciences, 1675 Observatory Dr., 53706 Madison WI, United States, [6] University of Minnesota, Department of Animal Sciences, 1364 Eckles Ave., 55108 Falcon Heights MN, United States

Mastitis is a costly disease that affects profitability and cow welfare. In the USA, the use of antibiotics is prohibited, in contrast to European organic farms, where their use is restricted but not strictly banned. Therefore, in both scenarios, it is essential to identify management practices to prevent mastitis so we can improve and enhance the future development of a growing organic dairy sector by improving milk quality and farm profitability, with practices that can be applied across diverse organic systems globally. The objective of this study was to describe risk factors and management practices and find associations to clinical mastitis (CM) incidence and bulk tank somatic cell score (BTSCS) on organic dairy farms across the USA. Through farm visits, we surveyed 82 organic farms in 12 states and evaluated milking systems. Farms were categorized by region as West (18%), Southwest (4%), Midwest (54%), Southeast (2%), and Northeast (22%). Farms were also categorized by size as small (<100 cows, 60%), medium (100 to 1000 cows, 28%), and large (>1000 cows, 12%). The average reported annual CM incidence was 12 ± 7 in 100 cows-year. The median milking herd size was 75 cows [range: 13, 4081]. The average daily milk yield was 23 ± 6 kg/cow/day. We found that 86% of farms overmilked their cows, including 53% using manual cluster removal. Also, only 4% of farms had optimal pulsator settings, 31% had unstable vacuum during milking, and 59% of farms performed milking system evaluations once per year or less. Our dataset had 85 variables. Dimensionality reduction was performed using principal components analysis and stepwise variable selection. Principal components (PC) and selected variables were used to build 4 models to explain variables associated with BTSCS and CM incidence. Region and farm size were forced into all models as covariates. For the first 2 models, where we used the first 2 PC (34% explained variance), we did not find any associations between the PC and BTSCS nor CM incidence. For the other 2 models, where we used the selected variables, milk yield (+0.5% ± 0.2/kg), rewarding employees for good milk quality (+7.7% ± 2), CM identification (red swollen quarter: -6.5% ± 3), and cluster removal method (automatic: -4.6% ± 3) were associated to CM incidence. Moreover, "bulk tank somatic cell count threshold of concern" (+0.006 ± 0.0001), the importance of employees in mastitis control (-0.2 ± 0.08), and the use of vaccines to prevent CM (+0.27 ± 0.13) were associated with BTSCS. In conclusion, perception and attitudes about mastitis, CM and milking system management explained most of the variability of our data and are associated with mastitis incidence and milk quality. One practical application of these results is that dairy farm advisors should emphasize frequent milking system evaluations.

Economic opportunities through shorter dry periods for Swiss dairy cows

C. Rudaz[1], A. Burren[1], S. Kohler[1], S. Grossrieder[1]
[1] Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences, Länggasse 85, 3052 Zollikofen, Switzerland

The health and fertility of high-yielding dairy cows are key determinants of biological andeconomic efficiency in dairy production. Shortening the dry period in multiparous cows hasbeen suggested as a management strategy to improve robustness, fertility, and profitability.This study evaluated the economic implications of shortened dry periods in Swiss dairysystems, focusing on milk yield, fertility, health-related costs, and farm-level profitability. The analysis was based on 12,012 lactations from Holstein cows evaluated by HolsteinSwitzerland. Lactations with dry periods of 30 and 60 days were compared regardingstandardized 305-day milk yield, fertility parameters (first insemination success, N3 index,number of inseminations per pregnancy, and delay time), and expected costs of relevanthealth disorders. Contribution margins were calculated for three production levels (9,000,10,000, and 11,000 kg milk per cow per year).Cows with a 30-day dry period produced approximately 100 kg more milk over 305 days thancows with a 60-day dry period. Fertility also improved: first insemination success increasedfrom about 70% to 80%, the N3 index declined from 10% to 5%, inseminations perpregnancy decreased from 1.5 to 1.3, and delay time was reduced from 45 to 35 days.Health-related costs were consistently lower with the shorter dry period.Although a shorter dry period increased basic feed costs due to a longer lactation period, thiswas more than compensated by lower costs for replacement, supplementary feeding, fertility,and health. Overall, contribution margins increased by CHF 69 to 150 per cow per year,depending on production level.These results suggest that shorter dry periods may represent not only an economicopportunity at farm level, but also a promising strategic option for Swiss dairy production.Under commercial farming conditions, this approach could support a better balance betweenproductivity, animal health, fertility, and sustainability, and may also be relevant for dairyregions facing similar challenges.

Iodine in the dairy chain: from measurement to farm management, product characterization and consumer knowledge

G. Niero[1], S. Censi[2], C. Mian[2], M. De Marchi[1]
[1] University of Padova, Department of Agronomy, Food, Natural resources, Animals and Environment, Viale dell'Università 16, 35020 Legnaro (Padova), Italy, [2] University of Padova, Department of Medicine, Endocrinology Unit, Via Giustiniani 2, 35128 Padova, Italy

Milk and its derived products are a cornerstone of human iodine intake, yet the levels of this essential micronutrient vary widely, reflecting the complexity of factors across the production chain. Ensuring a consistent supply of iodine begins with reliable analytical measurement and requires a holistic feed-to-fork perspective, encompassing farm management, industrial processing, and dietary consumption. In respect to the analytical framework, a fundamental first step is accurate measurement. "We can improve what we can measure": only with reliable and accessible analytical tools can the sector aim to standardize iodine content, enhance it where needed, and monitor products efficiently. Advances in rapid and cost-effective methods may offer new opportunities to guide decision-making throughout the chain. At farm level, feeding strategies and dietary supplementation, constitute the primary determinant, establishing a direct link between intake and milk content. Farm management practices, such as the use of iodine based teat disinfectants, may further contribute to transfer. Downstream, processing operations including pasteurization, skimming, cheese making, brining, and ripening, further shape the distribution and retention of iodine across diverse dairy products. All these dynamics generate notable variability among dairy matrices, from raw and commercial milk to cheeses, ricotta, and yogurt, likely affecting their contribution to recommended daily intake. In this scenario, consumer knowledge of dairy foods' role as a primary iodine source remains limited, emphasizing the importance of education and communication to fully leverage their nutritional potential. Addressing these challenges requires an integrated approach. By combining precise measurement, informed feeding and management practices, detailed product characterization, and enhanced consumer understanding, the dairy chain can maximize its contribution to human nutrition. Such a strategy not only supports public health but also reinforces the value of dairy products as reliable carriers of essential micronutrients in food systems. In this perspective, improved iodine management and clear product characterization may provide additional tools to differentiate dairy products and strengthen their positioning in the market as reliable dietary sources of iodine. A consistent and well-documented iodine content could support the use of nutrition claims on product labeling, while increased consumer awareness of their nutritional value may foster more informed choices, ultimately enhancing the attractiveness and overall perception of the dairy sector and its products. This research was funded by Bando 2022 PNRR Prot. P20228RP2Z "The relevance of iodine in human nutrition: filling the gap from the farm to the fork".

Association between calving interval, milk yield and early post-partum mortality among Swedish dairy cows

A. Hansson[1], M. Lindberg[2], R. Båge[3], A. Edvardsson Rasmussen[3], C. Kronqvist[2]
[1] Växa, PO Box 288, 75105 Uppsala, Sweden, [2] Swedish University of Agricultural Science, Department of Applied Animal Science and Welfare,, PO Box 7024, 75007 Uppsala, Sweden, [3] Swedish University of Agricultural Science, Department of Clinical Sciences, PO Box 7054, 750 07 Uppsala, Sweden

Calving interval (CInt) is a key management parameter in dairy herds, traditionally targeted at 12–12.5 months. Extended CInt has been reported to improve fertility without compromising milk yield, and have been suggested to benefit cow health by reducing exposure to the high-risk periparturient period. However, retrospective studies have associated prolonged CInt with increased mortality risk around calving. One proposed mechanism is that extended late lactation with low yield may lead to excessive body condition at calving and subsequent metabolic disorders. Cow mortality affects both farm profitability and consumer trust in the dairy sector. Given the rising mortality rates in high-producing dairy systems, clarifying the associations between milk yield and mortality around calving is therefore warranted. The objective was to study associations between CInt, milk yield and on-farm mortality within 30 days after third calving in Swedish dairy cows. Data from the Swedish Official Milk Recording Scheme included 139,444 cows with second–third CInt recorded between 2015 and 2022. Calving interval was categorized as <11.7, 11.7–13, 13–15 and >15 months. On-farm mortality was defined as euthanasia, unassisted death or slaughter on farm within 30 days postpartum. Milk yield was classified as second-lactation 305-day ECM (<9,000, 9,000–11,000, 11,000–12,000, >12,000 kg) or categorized into three classes: intermediate (±2 kg from herd average), high (>2 kg above), and low (>2 kg below). Associations were analyzed using logistic regression (SAS PROC GLIMMIX), including breed, CInt and yield class as fixed effects and herd as a random effect. Overall, 2,482 cows (1.78%) died within 30 days after third calving. No interaction between CInt and yield class was detected. CInt >13 months was associated with increased mortality risk ($p<0.05$), with the highest risk at >15 months. High-producing cows (>12,000 kg ECM) and cows above herd average at last insemination also had higher mortality risk. CInt and milk yield were associated ($p<0.001$): longer CInt was linked to higher 305-day yield, but to lower yield relative to herd average at last insemination, reflecting late-lactation decline. In a subset of particularly high-producing herds (n=150, 18,115 cows), no significant associations between CInt, yield and mortality were detected. Overall mortality was slightly lower (1.65%) than in the full dataset (1.8%). This may indicate that herd-level management in high-producing herds may mitigate potential adverse effects of prolonged CInts. Potential contributing factors may include superior dry cow and transition cow management, better reproductive decision-making and more targeted selection of cows for reinsemination, or other herd-level factors. These findings highlight opportunities to reduce mortality in practice through improved herd management and advisory strategies. High-performing herds may also have a more homogeneous population of high-yielding cows, potentially facilitating more consistent management decisions compared with the broader population. In conclusion, prolonged CInt in second lactation was associated with increased on-farm mortality within 30 days postpartum, particularly when exceeding 15 months, although this risk appeared less pronounced in high-yielding herds.

Automatic lameness detection in dairy cows using a limb-specific weighing platform

N. Herrmann[1], A. Burren[1], M. Hillen[2], A. Steiner[2], S. Kohler[1]
[1] Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences, Länggasse 85, 3052 Zollikofen, Switzerland, [2] Vetsuisse-Faculty, University of Bern, Clinic for Ruminants, Bremgartenstrasse 109a, 3012 Bern, Switzerland

Lameness is one of the most common and economically relevant health problems in dairy cows and remains a major challenge for animal welfare, labour efficiency, and sustainable herd management worldwide. Automated detection systems therefore represent an important field of development in precision livestock farming and may support dairy producers in improving health monitoring and management decisions. The aim of this study was to investigate whether lameness and/or claw disorders can be automatically detected using a limb-specific weighing platform. For this purpose, 54 dairy cows on two dairy farms in the canton of Lucerne (Switzerland) were weighed on a limb-specific weighing platform for 300 seconds each. Prior to weighing, each cow was assigned a locomotion score (LS) according to Sprecher et al. (1997). Within two days after weighing, functional claw trimming was performed by a professional claw trimmer. Claw disorders were documented according to the ICAR Atlas using the software "KLAUE", and a cow claw score (CCS) was calculated according to Sarbach et al. (2025). These data were expanded with existing datasets from comparable studies. In total, data from 337 dairy cows on eight farms were analysed using descriptive and statistical methods. To minimise bias caused by very heavy or very light animals, six weight parameters were defined to quantify asymmetric weight distribution, of which the three most suitable were included in the statistical models. A statistically significant association was found between LS and weight distribution, as well as between CCS and weight distribution, indicating that limb-specific weight distribution may serve as an objective indicator for automated claw health monitoring. However, the platform was only partly suitable for reliable lameness detection under practical conditions. The best-performing model achieved a sensitivity of 74%, meaning that 26% of lame cows were misclassified as healthy, while most other models identified fewer than 50% of lame cows. Specificity was considerably higher, ranging from 70% to 99%. The study also revealed a relatively high lameness prevalence compared with other studies, with approximately 25% at the animal level (n = 336) and 61% at the farm level (n = 42). These findings suggest that limb-specific weighing platforms are not yet sufficiently accurate as a stand-alone diagnostic tool for routine on-farm use, but they represent a promising basis for future early warning systems in commercial dairy production. In combination with additional animal-based indicators and claw health data, such systems could contribute to earlier intervention, improved herd management, reduced labour demand, better animal welfare, and lower lameness prevalence. Although this study was conducted in Switzerland, the approach is relevant for dairy farming more broadly and may support the transition towards more efficient and sustainable production systems in different dairy regions.

Cow hygiene and bedding microbiology in compost-bedded pack dairy systems with and without organic substrate

M. F. Caminati[1], J. L. Monge[2], D. Bueno[3], E. Reinoso[1]
[1] Universidad Nacional de Río Cuarto, Instituto de Biotecnología Ambiental y Salud (INBIAS-CONICET), Ruta 36 Km 601, 5804 Río Cuarto, Argentina, [2] Universidad Nacional de Villa María, I.A.P.Cs.BS.yAs., Arturo Jauretche 1555, 5900 Villa María, Argentina, [3] Instituto Nacional de Tecnología Agropecuaria, EEA Concepción del Uruguay, Concepción del Uruguay, Ruta Provincial 39 Km 143,5, 3260 Concepción del Uruguay, Concepción del Uruguay, Argentina

Compost-bedded pack (CBP) housing is increasingly adopted to improve cow comfort. However, bedding design and management may influence microbial dynamics, cow hygiene, and exposure to mastitis-associated microorganisms. We hypothesized that the inclusion of an organic substrate in CBP would be associated with lower and more homogeneous bacterial loads and improved cow cleanliness under commercial conditions. The objective of this study was to microbiologically characterize and compare two CBP systems used in dairy farms in the central basin of Córdoba Province, Argentina: CBP with added organic substrate (CB-S) and CBP without substrate (CB-W). Two commercial farms were evaluated. Composite bedding samples and milk samples from lactating cows were collected for microbiological analysis, and cow hygiene was assessed using a standardized visual scoring system across anatomical regions. Bacterial counts were $\log_{10}$-transformed prior to analysis and differences between systems were evaluated using analysis of variance ($p<0.05$). Environmental and opportunistic bacteria commonly associated with bovine mastitis were detected in both systems, including coagulase-negative staphylococci, Escherichia coli, Enterococcus spp., Corynebacterium spp. and Bacillus spp. Bedding from the CB-W system showed significantly higher bacterial loads than CB-S (8.58 ± 0.55 vs. 7.65 ± 0.09 $\log_{10}$ CFU/g; $P = 0.0182$) and greater bacterial diversity. Cows housed in CB-S showed significantly better hygiene scores than those in CB-W (1.05 ± 0.12 vs. 3.01 ± 0.10; $p< 0.0001$), with consistent differences across anatomical regions. These results indicate that bedding design influences both microbial conditions and animal cleanliness in CBP systems. The use of organic substrate was associated with more stable bedding conditions and improved hygiene, highlighting management strategies that may support udder health and contribute to One Welfare outcomes in dairy production systems.

Under construction – an approach to building animal welfare expertise in vocational training

C. Over[1], S. Ivemeyer[1], K. Cimer[1], J. Helmerichs[1], J. Brinkmann[1], S. March[1]
[1] Thünen Institute of Organic Farming, Trenthorst 32, 23847 Westerau, Germany

Expertise in animal welfare is essential for farmers in order to meet growing political and social demands for high animal welfare standards. To achieve these standards, intrinsic motivation among animal handlers and specialised knowledge in animal welfare is required. This expertise includes knowledge about the animals, practical skills in handling, and an empathetic attitude toward animals. Embedding this expertise in vocational training can promote animal welfare–oriented competence within the agricultural sector. The project 'Tierschutzkompetenz' [animal welfare expertise in vocational training of farmers], conducted by the Thünen Institute of Organic Farming, Institute of Vocational Education and Adult Education (IfBE) at Leibniz University Hannover (LUH) and the Agricultural Education Center Echem (LBZ), aimed to strengthen animal welfare competence in education through the development of teaching units and learning materials. As a first step an online survey gathered responses from 340 farmers in Lower Saxony who were registered as agricultural instructors for cattle, pigs, or both. They were asked about their understanding of animal welfare, the welfare tools they use on their farms, the training provided to agricultural apprentices regarding animal handling and transportation and their preferences for further education on animal welfare. The results showed that farmers perceive animal health as more important than the emotional state of the animal or the possibility to engage in natural behaviour. The instructors identified calmness and patience as the most important factors for successful interaction with animals. Accordingly, the handling of animals and low-stress stockmanship skills are considered important topics for further educational training. Existing data from farm management tools is used frequently for animal welfare management. Only about one-third of the respondents use special tools based on animal welfare indicators. Nine training units were developed for vocational training in cattle and pig husbandry. Their aim was to raise awareness and promote a balance between the three concepts of animal welfare: emotional state, animal health, and natural behavior. By teaching basic concepts of animal welfare, the training aims to enable participants to address animal welfare issues and actively participate in professional discussions on this topic. Existing units on animal welfare monitoring have been revised to help trainees to develop an eye for the animals by familiarising them with animal welfare indicators. One training session each for cattle and pigs teaches the basics of handling animals during transport. In order to further strengthen the anchoring of animal welfare in agricultural education and training, it is particularly important to improve cooperation between the various learning venues: the agricultural farm, the vocational school, and educational training centers. This cooperation is the focus of the follow-up project 'TiKoPLUS – animal welfare, competence and cooperation between learning venues'. 'TiKoPLUS' is funded as an InnoVET PLUS project by the Federal Ministry for Education, Family affairs Senior citizens, Women and Youth, granted by the Federal Institute for Vocational Education and Training (BIBB), (grant number 21IVP054C). The project 'Tierschutzkompetenz' was funded by the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE), grant number 2820MDT122.

The use of chlorophyll extract as post dipping in the photodynamic inactivation of microorganisms

R. Combuca Da Silva Junior[1], K. Souza Silva Campanholi[1], R. Aleson Dias Bezerra[2], W. Caetano[1], M. Soares Dos Santos Pozza[2]
[1] UEM, Chemistry, Av Colombo 5790, 87020-900 Maringa, Brazil, [2] UEM, Animal Science, Av Colombo 5790, 87020-900 Maringá, Brazil

According to the United Nations' 2030 Agenda, one of the sustainable development goals is to ensure sustainable consumption and production patterns. The need to ensure food safety includes, in addition to microbiological risks, concerns about antimicrobial-resistant bacteria. Mastitis is an inflammation of the mammary gland that directly affects milk production, generating economic losses and compromising the health of animals. In addition to reduced production and loss of mammary gland functionality, mastitis represents a risk to public health, as pathogenic microorganisms and their proteins can be transmitted through milk. Given these concerns, there is a growing interest in natural alternatives for the prevention and control of mastitis, effectively minimizing the use of antimicrobials. Photodynamic Inactivation of Microorganisms (IFDMO) is a treatment focused on the interaction between a photosensitizing compound and light of appropriate wavelength, which leads to the formation of highly reactive species capable of eradicating different strains of microorganisms. The present study explored the photodynamic efficiency of Chlorophyll Extract nanocapsulated in micellar copolymer Pluronic® F127 in post-dipping applications aimed at preventing subclinical mastitis and the quality of the milk produced was evaluated via somatic cell count (SCC). Chlorophyll was extracted from spinach (Spinacia oleracea). The bactericidal activity of chlorophyll extract encapsulated in F127 was evaluated against Staphylococcus aureus, and the MIC was determined in the concentration range between 13.6 and 0.1 mg mL-1. The analysis of microorganism growth determined an MIC of 6.8 mg mL-1 and a MBC of 13.6 mg mL-1. The Extract at a concentration of 3.40 (mg/mL) was incorporated into a copolymer matrix (F127). The experiment was carried out in the dairy cattle sector of the Iguatemi Experimental Farm (FEI) belonging to the State University of Maringá (UEM). The solution was applied to the teats of eight Holstein animals (Cross over) after milking and irradiation with the red LED source for 30 seconds. The control was carried out with 1000 mg mL-1 iodine solution. Milk collections were carried out on days 7, 14, 21 and 28. For the milk samples obtained, there was no statistically significant difference in the total aerobic mesophilic count when comparing the application of Chlorophyll Extract and the Control (iodine). Regarding the milk composition, the levels of the evaluated parameters are in accordance with the minimum standards required by current legislation IN 76/77 (BRAZIL, 2018). There was no difference between treatments in relation to Somatic Cell Count (SCC) $p>0.05$. The values of somatic cells were in accordance with the regulations in force in Brazil (5.36 log10 iodine and 5.35 log10 chlorophyll extract). The results obtained demonstrate the feasibility of using IFDMO with chlorophyll extract in post-dipping applications, guaranteeing the quality of the milk produced, since Photodynamic Inactivation is recognized for not generating bacterial resistance, being a promising alternative to the use of conventional antibiotics.

Integrative Characterization of Feed and Water Microbiomes in Dairy Production Systems

S. Duarte-Coimbra[1,2,3], L. Pérez-Pardal[1,2,3], A. Beja-Pereira[1,2,4]
[1] Centro de Investigação em Biodiversidade e Recursos Genéticos (CIBIO), InBIO Laboratório Associado, Universidade do Porto, Rua Padre Armando Quintas 7, 4485-661 Porto, Portugal, [2] BIOPOLIS Program in Genomics, Biodiversity and Land Planning, Rua Padre Armando Quintas 7, 4485-661 Porto, Portugal, [3] Departamento de Biologia, Faculdade de Ciências, Universidade do Porto, Rua do Campo Alegre, 4169-007 Porto, Portugal, [4] DGAOT, Faculdade de Ciências, Universidade do Porto, Rua do Campo Alegre, 4169-007 Porto, Portugal

European dairy production has intensified toward larger farms, improving productivity but raising concerns about biosecurity, animal welfare, and sustainability [1]. Forage acts as both a nutrient source and a microbial reservoir, while drinking water, despite constant animal contact, remains underexplored [2].So far, studies have characterized individual compartments using short-read sequencing but rarely integrated feed-water systems or examined the effects of farm size [3].To address this gap, we characterized the microbiomes of 18 Portuguese dairy farms, categorized by size and selected based on biosecurity level.We aimed to establish a foundational understanding of feed/water microbiomes and generate actionable knowledge to improve management, enhance biosecurity, and sustain dairy systems. We tested: (H1)forage type is a primary driver of bacterial, fungal, and viral communities in feed; (H2)biosecurity and water system cleaning frequency as determinants of pathogen load and diversity in drinking water; and (H3)feed-water sharing a core set of potentially pathogenic taxa, suggesting microbial links across farm compartments. Samples were collected from feed bunks (50g) and water troughs (250 ml filtered with 0.22 µm filters). Total DNA extracted and sequenced using Nanopore long-read technology. Low DNA yield prompted amplicon sequencing of water samples and shotgun metagenomics of feed samples. Taxonomic profiles were generated using Epi2ME; functional annotation was performed using EggNOG-mapper/FunFun for fungi and Prokka/PICRUST2 for bacteria. Clostridium and Lactococcus dominated bacteria, Pichia and Cutaneotrichosporon fungi in water;while Acetobacter and Lactobacillus dominated bacteria, and Pichia and Saccharomyces fungi in feed. Feed microbiome was characterized by low diversity,while water exhibited greater richness. Feed and water shared 20% of the total microbial taxa and 80% of the potential pathogenic organisms detected, including Aspergillus flavus and Klebsiella pneumoniae. A higher pathogenic load in feed samples was detected in farms with lower biosecurity levels.In water samples, this pattern was found in farms with infrequent cleaning of water troughs. Forage type and water-trough cleaning frequency emerged as the strongest microbial management levers in dairy systems.Despite high taxonomic turnover, functional profiles remained broadly conserved, with feed enriched in fermentation pathways and water exhibiting enhanced nutrient cycling activity, indicating ecological redundancy that stabilizes dairy farm microbiomes under changing management conditions.The shared pathogen core between feed and water justifies integrated monitoring programs via ONT multi-domain profiling. These findings establish actionable ecological benchmarks linking microbiome management to animal health, productivity, and dairy biosecurity across production scales. Immunomodulatory Effects of Bacterial Extracellular Vesicles from Wild and ATCC Escherichia coli and Staphylococcus aureus: A Comparative In Vitro Study

M. Penati[1], D. L. S. Dos Santos[2], R. I. Lazar[1], O. Balbi[1], M. C. Gilioli[2], I. Maluf[2], M. Y. R. Cieza[2], Y. Dadi[1], G. Salvi[1], F. Ceciliani[1], N. C. C. Silva[2], C. Lecchi[1], L. G. De Matos[1,2]

[1] Università degli Studi di Milano, Department of Veterinary Medicine and Animal Science, Via Dell'Universita, 6, 26900 Lodi, Italy, [2] Universidade Estadual de Campinas (UNICAMP), Department of Food Science and Nutrition, Rua Monteiro Lobato, 80, 13083-862 Campinas, Brazil

Bovine mastitis remains one of the most significant challenges affecting dairy production, with Escherichia coli and Staphylococcus aureus being among the most prevalent causative agents. Beyond bacterial colonization, extracellular components such as bacterial extracellular vesicles (BEVs) may contribute to host inflammatory responses and tissue damage. This study compares the effects of wild isolates and reference ATCC strains of E. coli and S. aureus on cell death and inflammatory responses in vitro. BEVs are isolated from field strains obtained from mastitic milk and from the corresponding ATCC strains by serial centrifugation and ultracentrifugation. Characterization is performed using Western blotting, cryo-electron microscopy, flow cytometry, and nanoparticle tracking analysis (NTA). Their biological effects are evaluated using bovine polymorphonuclear cells (PMNs) as a proxy for somatic cells present during mastitis. Three different concentrations of each BEV protein preparation were tested. Cell viability and proliferation are assessed using the WST-1 assay to determine cytotoxic effects, while inflammatory activation is evaluated by measuring inflammasome-associated caspase-1 activity. Preliminary observations suggest that wild isolates may induce higher levels of cell death and a stronger upregulation of pro-inflammatory mediators compared to ATCC reference strains. E. coli treatments appear to be associated with a more pronounced acute inflammatory response, whereas S. aureus may exhibit a comparatively moderate but potentially sustained effect. BEVs derived from wild isolates are expected to trigger measurable inflammatory signaling, supporting their possible contribution to host–pathogen interactions even in the absence of viable bacteria. These findings highlight potential differences between laboratory reference strains and field isolates in their capacity to modulate inflammatory responses. Understanding these variations may improve knowledge of mastitis pathophysiology and support the development of more accurate in vitro models and diagnostic biomarkers for dairy health management.

Social Intermittent Suckling: Easing Weaning for Piglets and Sows

L. Fabà[1], L. Ferreres-Serafini[1,2], P. Langendijk[1,3], J. F. Pérez[2], S. M. Martín-Orúe[2], H. M. J. Van Hees[1,4]
[1] Trouw Nutrition R&D, Swince Research Centre, Veerstraat 38, 5831 JN Boxmeer, Netherlands, [2] Universitat Autònoma de Barcelona, Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Edifici V, 08193 Bellaterra, Spain, [3] Wageningen University and Research, Adaptation Physiology, Droevendaalsesteeg 4, 6708 PB Wageningen, Netherlands, [4] Ghent University, Department of Veterinary and Biosciences, Faculty of Veterinary Medicine, 9820 Merelbeke, Belgium

This study compared conventional continuous suckling (CW; n = 17 sows) with social intermittent suckling (SIS; n = 18 sows) to evaluate sow energy balance and piglet performance before weaning (24 d) and during the post-weaning period. In the SIS treatment, sows were progressively separated from their litters for 4 to 10 h/day during the last 11 days pre-weaning, while piglets were co-mingled and had access to creep feed. Post-weaning performance was evaluated in a split-plot design using electronic feeding stations, with piglets housed in 12 pens of 12 animals each (n = 144). Despite similar feed intake (~5.5 kg/day), SIS sows experienced a less negative net energy balance compared with CW sows (–20 vs. –30 MJ/day; $P < 0.01$), as estimated using Noblet and Dourmad equations adjusted for creep intake. This was associated with lower milk energy output (48.4 vs. 56.2 MJ/day) and reduced milk protein yield (493 vs. 538 g/day; $P < 0.05$). Consequently, SIS sows mobilized less body protein (70 vs. 147 g/day; $P < 0.01$) and fat (341 vs. 520 g/day; $P = 0.01$), and tended to lose less backfat (3.6 vs. 5.1 mm; $P = 0.081$). Before weaning, SIS piglets consumed more creep feed than CW piglets (52.8 vs. 24.9 g/pig/day; $P < 0.001$), with peak intakes reaching ~105 g/pig/day. Creep feed contributed ~13% of energy intake and ~14% of growth in SIS piglets, compared with ~5–6% in CW piglets ($P < 0.001$). This partial substitution of milk resulted in lower pre-weaning average daily gain (222 vs. 261 g/day; $P < 0.01$) and lighter weaning weight (6.3 vs. 6.8 kg; $P < 0.01$). During the early post-weaning period, SIS piglets showed markedly higher feed intake and average daily gain (+66–67%; $P < 0.001$). These differences persisted throughout the nursery phase, resulting in 2.2 kg higher body weight at day 34 post-weaning (19.6 vs. 17.4 kg; $P = 0.001$). In conclusion, SIS reduced sow metabolic load during late lactation and promoted early solid feed intake by piglets, resulting in accelerated post-weaning growth despite a modest reduction in pre-weaning performance. SIS appears to be a functional management strategy to support gradual weaning while preserving sow condition.

The future perspectives of increasing within-litter body weight uniformity in pigs

K. Hooyberghs[1,2], S. Goethals[3], W. Gorssen[4], S. Millet[3], S. Janssens[1], N. Buys[1]
[1] KU Leuven, Department of Biosystems, Center for Animal Breeding and Genetics, Kasteelpark Arenberg 30, box 2472, 3001 Leuven, Belgium, [2] Unit of Animal Genomics, GIGA and Faculty of Veterinary Medicine, University of Liège, Avenue de l'Hôpital 11, 4000 Liège, Belgium, [3] ILVO, Burg. Van Gansberghelaan 119, 9090 Merelbeke – Melle, Belgium, [4] ETH Zürich, Animal Genomics, Universitätsstrasse 2, 8092 Zürich, Switzerland

Increasing within-litter body weight uniformity remains a major challenge in modern pig production. In a 4 year research project, we demonstrated that lower uniformity of body weight is associated with more lightweight piglets, reduced growth performance and increased mortality. Factors influencing weight uniformity were investigated across the entire lifespan of pigs and strategies to reduce variation throughout the production cycle were evaluated. Uniformity metrics were strongly correlated, indicating that simpler measures such as within-litter weight range or the proportion of lightweight piglets can reliably replace more labour-intensive metrics that require weighing all piglets individually, like coefficient of variation or standard deviation. However, we think that future progress will depend strongly on improved phenotyping. Automated technologies, such as computer vision and precision livestock systems, may enable continuous and objective monitoring of body weight, feed intake, farrowing processes and growth stability, reducing labour demands and advance our understanding of within-litter body weight uniformity. These innovations are expected to make large-scale monitoring of uniformity traits more feasible. In a first study, we showed that uniformity is dynamic, with major shifts around weaning. Weak correlations were found between birth weight uniformity and post-weaning uniformity indicating that these are two distinct traits: one before weaning, closely linked to pre-weaning survival and one after weaning, relevant during the finishing phase and at slaughter. Larger litters, more mummified and stillborn piglets, higher sow parity and larger chest circumference were associated to an increased body weight variation, whereas a higher number of functional teats was linked to higher uniformity. Individual growth performance depended on birth interval, sex ratio, sow body condition loss, litter size and weaning age, emphasizing the need to balance litter size with the sow's capacity. As maternal features play a major role, breeding goals may need to shift from maximizing litter size to optimizing the number of uniformly growing, robust piglets relative to the capacity of the sow. Second, we tested the effect of feeding interventions around weaning, which showed only short-term effects on body weight uniformity. However, literature suggests that the gut microbiome may influence early-life growth trajectories and piglet robustness. New approaches may be more succesful. In a third phase, we conducted an intervention trial to evaluate a genetic strategy to reduce variation. Estimated breeding values for uniformity and survival of terminal Piétrain sires showed only weak correlations with within-litter uniformity in their crossbred offspring, indicating limited predictive value for this trait. Nonetheless, meaningful associations were observed with growth stability, suggesting that uniformity and resilience traits could contribute to more refined breeding goals. Overall, the results demonstrate that within-litter uniformity is shaped by a complex interplay of maternal, genetic and management factors. Future pig production should shift its focus from increasing litter sizes to increasing piglet quality, which will eventually benefit the animals, the farmers and the pig industry as a whole.

Dietary combination of β-galactomannans, plant extracts and monoglycerides improves survival and performance in post-weaning piglets

P. Martín-Atance[1], S. Carné[1], M. Verdú[2], X. Soldevila[2], J. Estévez[1]
[1] Industrial Técnica Pecuaria, S.A. (ITPSA), R&D, Av. de Roma 157, 7th floor, 08011 Barcelona, Spain, [2] bonÀrea Agrupa, Animal Nutrition and Feed Industry, Carrer de Ponent, 5, 25210 Guissona, Spain

During the post-weaning period, piglets are highly susceptible to enteric disorders which negatively impact their health, welfare and overall productivity. Hydrolysable β-galactomannans (HβG) may compete with pathogens for epithelial adhesion and exert prebiotic effects and can modulate intestinal morphology and cytokine expression. In combination with phytogenic extracts (PHY) and short- and medium-chain fatty acid (FA) monoglycerides, these compounds may enhance resilience during this stage. The hypothesis of this study was that the inclusion of 3,000 ppm of a complementary feed containing HβG, selected PHY, and short- and medium-chain FA monoglycerides, would improve survival and growth performance of weaned piglets reared under intensive farming conditions. A total of 252 piglets (Large White × Landrace females × Pietrain males; 24 d of age; 6.3 ± 1.44 kg) were allocated to 21 pens (12 piglets/pen), in two rooms, in a randomized design with two treatments: control diet and control + 3,000 ppm of a dietary combination of HβG, phenylpropanoids from PHY, and short- and medium-chain FA monoglycerides (EG; ENAGUT®). The trial lasted 42 d (pre-starter: d0–14; starter: d15–42). Growth performance, mortality, health status and faecal consistency (Hu et al., 2012) were recorded periodically. Pen was the experimental unit. Data were analysed using a mixed-effects model with repeated measures (SAS 9.4), including treatment, period and their interaction as fixed effects, and pen and room as random effects. Results are expressed as mean ± SEM and significance was declared at $P < 0.05$ and trends at $P \leq 0.10$. During the starter phase, EG reduced mortality to 0.00% compared with 6.82% in control group ($P < 0.01$). Overall, mortality over 42 d was also lower in supplemented piglets (2.37 vs. 7.50%; $P < 0.05$). No significant differences were detected in feed intake or faecal consistency. A trend of increase in the average daily gain vs. control was observed during the starter phase (0.40±0,08 vs. 0.38±0,09 kg/d; $P = 0.09$). Over the whole study, supplemented piglets showed numerical improvements in final body weight (19.30±4,17 kg vs. 18.59±4,32 kg; +3.7%), average daily gain (0.31±0,07 kg/d vs. 0.29±0,07 kg/d; +6.5%), and feed conversion ratio (1.48±0,15 vs. 1.53±0,34; −3.4%), although these were not statistically significant ($P > 0.05$). The absence of differences in faecal consistency suggests that improved survival was not primarily associated with reduced diarrhoeal expression but may reflect systemic effects on host resilience. Nutritional modulation of immune function is recognized as a key determinant of robustness during weaning. The survival advantage observed with EG may therefore involve enhanced immune competence, improved inflammatory balance, and strengthened mucosal defence mechanisms, as well as control of microbial load and dysbiosis. From a production perspective, reductions in post-weaning mortality exert a leveraged effect on whole-cycle profitability by increasing the number of pigs entering the grower–finisher phase and optimizing facility utilization. Thus, beyond performance metrics alone, enhanced early-life survival represents a relevant driver of productive efficiency and economic sustainability. In conclusion, supplementation with 3,000 ppm EG improved significantly survival and tended to enhance growth performance in post-weaning piglets reared under intensive conditions.

Effect of supplementing gestating and lactating sow with a Citrus-based sensory feed additive on sow reproduction and piglet performance

J. Foglio[1], J. F. Gabarrou[1], E. Arnaud[1]
[1] Laboratoires PHODE, Animal Care, 8 Avenue de la Martelle, 81150 Terssac, France

Essential oils and plant extracts have shown beneficial effects on stress management in swine. The aim of this trial was to assess the effects of supplementing gestating and lactating sow with a sensory feed additive, based on Citrus sinensis essential oil, on sows' tear staining, reproductive performance, and piglet growth. This trial was conducted in a commercial farm in France. A total of 86 sows (Hypor) were monitored across four batches: two control batches (n=37) and two treated batches (n=48). Parity distribution was balanced between groups to avoid experimental bias. Both groups received standard gestation, peripartum, and lactation diets according to their physiological stage. The treated group received a supplementation with a citrus-based sensorial feed additive (Laboratoires Phodé) at 250 g/tonne of feed. Litter body weight was measured at day 7 and day 28, from this, litter growth was calculated. Sow body condition was evaluated by measuring backfat thickness using a backfat meter (Renco, Schippers, France) at day 7 and day 28. Backfat differences was calculated. Tear staining was scored using a 5 points scale (0 = no staining to 4 = severe staining), as a marker of stress status. All data were analysed by a Student's t-test using SAS software, except the tear staining scores, which were analysed by a Khi square test using SAS software. The average number of piglets at day 7 were similar between treatment groups. Litter weight at weaning (day 28) was higher by 3.7 kg in the treated group compared to the control group (65.8 vs 69.4 kg; $p = 0.1$). Backfat loss during lactation was reduced by 2 mm in the treated group compared to the control group (-4.1 vs -2 mm; $p=0.05$). Tear staining scores differed significantly between groups ($p<0.001$). There was a higher proportion of animals classified in score 1 in the treated group compared to the control group (9.6 vs 31 %). The control group presented a greater percentage of sows in score 3 compared to the treated group (40 vs 20.7 %). There were no sows presenting score 4 in the treated group and 15.4 % in the control group. Supplementing sows with specific sensory feed additive improves the psychosocial state of sows during lactation, limits the loss of body condition in sows during lactation, and improves litter weight at weaning.

Effects of different combinations of dietary zinc and copper sources on their homeostasis, mitochondrial function, ATP concentrations and antioxidant response in different tissues in post-weaned piglets

J. V. Da Silva Duarte[1,2], J. S. Bee Tubin[3], I. Audet[1], D. Bueno Dalto[1]
[1] Agriculture and Agri-Food Canada, Sherbrooke R&D Centre, 2000 College, J1M0C8 Sherbrooke, Canada, [2] University of Saskatchewan, Department of Large Animal Clinical Sciences, 105 Administration Pl, S7N5A2 Saskatoon, Canada, [3] Universidade Estadual de Santa Catarina, Department of Animal Science, 680E Beloni Trombeta Zanin, 89815630 Chapeco, Brazil

The restrictions on the use of zinc oxide (ZnO) during the post-weaning period in the European Union have intensified the discussions to reduce pharmacological Zn levels worldwide. In Canada, total dietary Zn will be limited at 300 ppm although it is still not clear if such levels are sufficient to meet immediate post-weaning requirements and sustaining robustness. This study evaluated the effects of inorganic (I) and organic (O) Zn (ZnO or Zn proteinate) and Cu (CuSO4 or Cu-amino acid complex) sources on their homeostasis and metabolic health parameters in pigs. At weaning (d21), 90 piglets were randomly assigned to four diets combining Zn and Cu sources (IZnICu, OZnOCu, IZnOCu, OZnICu) at 300 and 130 ppm, respectively. Samples were collected at d21, 28, and 35 to evaluate Zn and Cu concentrations and antioxidant response in plasma, jejunum mucosa, liver, and mRNA expression of selected genes, mitochondrial Zn and Cu concentrations, cytochrome c oxidase activity, and ATP concentrations in jejunum mucosa and liver. Statistical analysis compared each treatment vs pre-treatment levels (d21) in addition to a 2×2 factorial contrast between the different combinations of sources at d28 and 35. Compared to d21, plasma and liver Zn concentrations were lower in all treatments at d28 and 35 ($P \leq 0.08$), except plasma Zn in IZn groups at d35 that was not different from d21 ($P \geq 0.45$). Plasma and hepatic Cu concentrations were not different from d21 ($P \geq 0.20$) whereas plasma Cu did not differ among treatments ($P \geq 0.18$) but hepatic Cu tended to be higher in IZn piglets than OZn at d28 ($P = 0.07$). Jejunal ZIP4 mucosa mRNA expression at d28 was enhanced by IZn only when combined with ICu (interaction; $P = 0.07$). In jejunum mucosa ($P \leq 0.09$) and liver ($P \leq 0.05$), IZn increased MT3 expression at d28 and 35. The expression of ZIP5, ZnT1, CTR1, ATOX1, ATP7A (jejunum only), and ATP7B (jejunum and liver) were not affected by treatments ($P \geq 0.12$). At d28, OZn increased jejunal mitochondrial Zn in OCu piglets but not ICu (interaction; $P = 0.06$) whereas hepatic mitochondrial Zn was higher in IZn than OZn groups ($P = 0.05$). Hepatic cytochrome c oxidase activity increased only in OZnOCu piglets (interaction; $P = 0.05$) and hepatic ATP concentrations tended to be greater in OZn groups ($P = 0.10$). No treatment effect was detected on plasma and jejunal SOD and GPX activities or carbonyl protein concentrations ($P \geq 0.12$). Liver SOD activity was higher for OZn piglets than IZn (d35, $P = 0.01$; trend at d28, $P = 0.10$), and higher for OCu piglets than ICu at d28 ($P=0.05$). Carbonyl protein concentrations at d28 tended to be lower for OCu than ICu groups ($P=0.10$). In conclusion, regardless of source, 300 ppm Zn was not sufficient to maintain body Zn status during the first post-weaning week but, in combination with 130 ppm Cu, avoided the commonly observed drop in Cu status after weaning. Piglets fed IZn showed increased MT3 expression and hepatic mitochondrial Zn accumulation whereas OZn demonstrated superior functional hepatic outcomes related to ATP synthesis and antioxidant response, suggesting better functional accessibility of the organic source.

The use of blood biomarkers to evaluate the impact of acute heat stress in piglets and growing finishing pigs

U. M. Mccormack[1], E. Perez-Calvo[1], J. Zhang[2], Z. Wang[2], S. Wang[2], A. J. Cowieson[1]
[1] dsm-firmenich, ANH, Wurmisweg 576, 4303 Kaiseraugst, Switzerland, [2] dsm-firmenich, ANH, R&D center, 065799 Bazhou, China

Heat stress (HS) disrupts metabolic, physiological, and immune functions in a systemic manner, ultimately compromising growth and overall performance of animals. Pigs are particularly vulnerable to HS, and their capacity to dissipate excess heat decreases as they grow, making older animals more susceptible. A better understanding of the physiological responses to HS using minimally invasive approaches is essential to predict, prevent, and monitor the effectiveness of mitigation strategies. This study assessed acute HS induced changes in piglets and growing finishing (GF) pigs using blood biomarkers. A total of 96 pigs (21d old; 6.7-88.7kg BW over 112 days) were housed at thermoneutral temperatures across production phases. Pigs were offered commercial diets at NRC levels. Animals were exposed to two acute HS challenges: piglets on days 26-28 (6 h at 36-38 °C; 18 h at 30-32 °C), and GF pigs on days 54-56 (6 h at 30-32 °C; 18 h at 28 °C). One pig per pen was sampled on d 25, 29, 53 and 57. Blood biomarkers were analyzed for hematology, oxidative stress biomarkers via commercial assay kits, point of care devices iSTAT CG8+ cartridge, and VetScan Comprehensive diagnostic profile. Data were analyzed in JMP Pro 18 using a repeated-measures mixed model, with day as the repeated factor, pig as the subject, and an unstructured covariance matrix. Multiple comparisons were conducted using Students t-tests, with significance defined as $P<0.05$. Total protein, monocytes (count and %), and LPS-binding protein (ug/mL) were higher after HS in both phases, whereas red blood cells (10^{12}/L) hematocrit (%) and alkaline phosphatase (U/L) were lower after HS ($P<0.05$). Additionally, neutrophils (count and %), red cell distribution width (fL and %) were lower in piglets after HS but higher in GF pigs after HS. Malondialdehyde (nmol/mL) was higher in piglets after HS but lower in GF after HS ($P<0.05$). In piglets, superoxide dismutase (U/mL) and hemoglobin (g/L) were lower after HS, whereas total antioxidant capacity (nmole/uleq), potassium (mmol/L), alkaline aminotransferase (U/L), mean corpuscular hemoglobin (g/L and pg) and mean corpuscular volume (fL) were higher after HS ($P<0.05$). In GF pigs, blood urea nitrogen (mg/dL) and glucose (mg/dL) were lower after HS, whereas eosinophils and lymphocytes (both count and %), plateletcrit (%), and platelet (10^9/L) were higher after HS ($P<0.05$). Biomarkers impacted due to HS in both growth phases could provide insights into metabolic and biological impacts of temperature on health and performance capabilities. These differences over time, especially those differing between piglet and GF phases, can demonstrate age-dependent metabolic and physiological responses to heat exposure. Changes during both HS periods may also indicate increased water consumption resulting in hemodilution. Fluctuations in the concentrations of blood hematological parameters due to HS suggest impacts on the immune and inflammatory responses, as well as oxidative stress (OS) markers, which appeared to be more impacted in the piglet phase, indicating their ability to deal with redox imbalance may be impaired during this phase. In addition, biomarkers related to metabolic parameters like BUN and glucose can provide insights into HS impacting metabolism and nutrient utilization, and these being observed in the GF phase may suggest that older animals have impaired feed intake due to HS. In conclusion, blood biomarkers provide a valuable tool to monitor physiological alterations in piglets and GF pigs subjected to short-term HS, supporting the development and validation of heat-mitigation strategies.

Participatory identification of feasible pig welfare innovations to support resilient farming systems under evolving EU legislation

N. J. Tirchett[1], E. Garcia Manzanilla[1], V. A. Moustsen[3], A. Valros[4], P. Chevillon[5], V. Courboulay[5], P. Ferrari[2], J. Lorente Martín[6]

[1] Teagasc, Pig & Poultry Research & Knowledge Transfer Department, Animal & Grassland Research and Innovation Centre, Moorepark, P61 C996 Fermoy, Ireland, [2] CRPA - Research Centre for Animal Production, Viale Timavo 43/2, 42121 Reggi Emilia, Italy, [3] SEGES Innovation P/S, Agro Food Park 15, 8200 Aarhus N, Denmark, [4] Research Centre for Animal Welfare, Faculty of Veterinary Medicine, P.O. Box 57, 00014 University of Helsinki, Finland, [5] IFIP - Institut du Porc, La Motte au Vicomte, 35650 Le Rheu, France, [6] Pig333, C/ Domenech Casamira, 3, 17500 Ripoll (Girona), Spain

The European animal welfare regulation is currently under review to improve housing and management of pigs. However, resilience of pig production systems depends on identifying welfare improvements that are not only scientifically sound but also practically and economically feasible under commercial conditions. Structured, multi-country evidence of such implementable practices remains limited. The WelFarmers project, funded through Horizon Europe, aimed to identify and evaluate pig welfare practices that enhance system resilience while remaining feasible across diverse European production contexts. WelFarmers includes 8 regional networks established in Denmark, Finland, France, Ireland, Italy, Portugal, Romania and Spain representing more than 50% of the pig herd across the EU. A bottom-up, multi-actor approach was applied, engaging farmers, advisors, veterinarians and researchers. Two rounds of good practice collection were conducted across four priority themes: loose housing of lactating sows; production of pigs with undocked tails; pain mitigation in castration / production of entire males; and space allowance & flooring for growers and finishers. A total of 200 submitted practices were evaluated using a structured multi-criteria scoring system (0-5 scale) assessing technical quality, impact, and probability of successful implementation across welfare, economic and environmental dimensions. Practices that achieved consistently high scores across the three evaluation domains were prioritised for final selection through stakeholder voting within the networks. Across themes, high-ranking practices demonstrated that welfare-oriented management and housing adaptations can be integrated into existing commercial systems without compromising operational feasibility. Strong farmer engagement throughout the evaluation process reinforced the practical relevance and transferability of the selected innovations. An environmental and economic assessment of the winning practices is being conducted to further evaluate cross-country applicability and sustainability implications. The selected practices are also being documented and presented through technical summaries, visual media and virtual farm demonstrations to facilitate knowledge transfer and uptake across the European pig sector. These results highlight the value of participatory networks in bridging the gap between legislative ambition and farm-level implementation. The identified practices provide evidence-based, field-validated examples to support resilient pig production systems capable of adapting to evolving societal and regulatory expectations.

Updated Drinking Water Requirements and Key Influencing Factors in Cattle, Pig and Poultry Production

L. De Prekel[1], A. Van De Sompele[1], M. Lamerand[1], K. Goossens[1]
[1] Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Burg. Van Gansberghelaan 119, 9090 9090 Merelbeke-Melle, Belgium

Drinking water supply is a critical factor for maintaining optimal performance in farm animals. In the context of climate change, water resources for animal husbandry are becoming increasingly limited, with prolonged dry periods intensifying scarcity. At the same time, ongoing genetic improvements in livestock have increased animals' performance and maintenance requirements, creating a growing need to update reference values for drinking water consumption. This study quantified drinking water requirements in three major livestock sectors, cattle, pigs, and poultry, and identified key factors influencing water consumption. Water meters were installed on 7 dairy farms, 4 beef farms, 7 pig farms and 6 poultry farms, and daily water consumption was monitored for one full year. Where possible, different animal categories (e.g. piglets, fattening pigs, lactating sows) were measured separately. The dataset comprised more than 50,000 daily observations for the three sectors, accompanied with detailed metadata including genetics, diet composition, climate parameters, (re)production parameters and drinking system characteristics. Updated drinking water consumption values were established and influencing factors were identified for each livestock sector. For beef cattle, dairy cattle, and pigs, mean water consumption values for most animal categories were higher than the reference values currently used in Flemisch environmental permits. The temperature–humidity index showed a highly significant effect on water consumption across all sectors, especially in high-performing animals such as lactating and gestating cows and sows. In dairy cattle, water consumption increased significantly with increasing milk yield ($p < 0.001$), feed intake ($p < 0.001$), and dry matter content of the diet ($p < 0.001$). In pigs, water consumption increased significantly with age in both piglets ($p < 0.001$) and fattening pigs ($p < 0.001$). Furthermore, farrowing sows showed a mean increase of 0.976 L ($p < 0.001$) per present day in the farrowing unit. In poultry, water consumption also increased significantly with age ($p < 0.001$) in laying hens and broilers, and genetic lines showed distinct differences in water consumption at equal ages. Overall, drinking water requirements were consistently higher than historical reference values used in Belgium, and water consumption was shown to be influenced by multiple biological and environmental-related factors. These updated values and insights provide essential input for more accurate water requirement estimates under changing climatic conditions.

Natural Behaviour and Activity Pattern of Pigs: A comparative study of breeds and environments

M. Wolf[1], R. Thomsen[2], M. L. Buus[2], J. Küper[3], K. Frölich[3], I. Czycholl[1]
[1] Copenhagen University, Department of Veterinary and Animal Science, Grønnegårdsvej 15, 1870 Frederiksberg C, Denmark, [2] Innovations Center for Økologisk Landbrug, Agro Food Park 26, 8200 Aarhus, Denmark, [3] Tierpark Arche Warder, Langwedeler Weg 11, 24646 Warder, Germany

Understanding pigs' natural behaviour is essential for improving housing and management practices that promote their behavioural expression and ensure their needs are met. This study therefore aims to improve the understanding of pig behaviour by examining daily activity patterns, natural behaviours, and the influence of breed and environment. The research addressed the following questions: How do pigs allocate their time across daily activities? Are there behavioural or activity differences between breeds? Do rooting, resting, play behaviour, and social interactions differ between pigs housed in stables and those kept in field conditions? Furthermore, it was hypothesized that there would be no significant differences in daily activity patterns between breeds, while pigs in field conditions would show more rooting and play, less resting, and fewer negative social interactions compared to stable-housed pigs. Two behavioural experiments using direct observation were conducted for a total of 48 days; 24 days for each experiment divided over three periods. The first experiment investigated three breeds (Angeln Saddleback, Linderöd, and Mangalitza) in a semi-natural environment. All observations were conducted between 9:10-16:10 with each observation session lasting 20 minutes. The behavioural observations were based on continuous group sampling and the ethogram covered the following behaviours: eating, drinking, foraging behaviour, locomotion, resting and sleeping, play behaviour, eliminative behaviour, social behaviour, sexual behaviour, comfort behaviour and others. The second experiment compared slaughter pigs housed on the same organic farm in organic stables with those kept in field accommodations. All observations were conducted between 9:15-16:30 and one observation round took 31 min. The ethogram covered the following behaviours: rooting, resting, social interactions and play behaviour, with scan sampling used for rooting, resting and social interactions and play behaviour recorded with event sampling. Data were analyzed in R. Differences between breeds were analyzed using a Kruskal–Wallis test for all behaviours. When significant, pairwise Mann–Whitney U tests were conducted to identify specific breed differences. A Bonferroni correction was applied to control for Type I error. Differences between housing systems were analyzed via Mann– Whitney U tests carried out for each behaviour defined in the ethogram. Results showed that pigs in semi-natural environment devoted most of their active time to foraging (20–40%) and eating (17–20%), while resting accounted for 12–44% depending on breed. Significant breed differences ($p < 0.05$) were found between Linderöd and the two other breeds in the duration of the behaviour categories: eating, resting, drinking, elimination and others, with Linderöd being the most active breed. In the study concerning slaughter pigs, pigs with field access rooted and played significantly more ($p < 0.05$) and rested less during daytime activity than pigs in stables, supporting the hypothesis that environment strongly shapes behavioural expression. Overall, the findings highlight that pigs are highly active animals with a strong need to forage. This holds despite the fact that breed may influence the duration of certain behaviours. Housing environment had a clear impact, underlining the importance of providing conditions that enable pigs to express their natural behaviour and thereby improve welfare.

Changes in body dimensions of Irish sows over 20 years

A. Foley[1,2], L. Boyle[1], K. O'Driscoll[1], L. Jessiman[2], E. Baxter[2]
[1] Teagasc, PPDD, Moorepark, P61 P302 Fermoy, Ireland, [2] SRUC, ABW, Nicholas Kemmer Road, EH9 3FH Edinburgh, United Kingdom

The phasing out of traditional farrowing crates is currently being discussed by the EU commission. This presents an opportunity for adoption of well-designed alternative housing which requires an understanding of the needs of the animals, knowledge of sow body dimensions and changes in litter size to ensure the provision of appropriate space to perform natural behaviours. The aim of this study was to measure the body dimensions of sows on Irish commercial farms and evaluate changes since similar work was conducted in 2005. The body dimensions of 490 sows across all parities from across four Irish commercial farms were measured. Sows were measured from snout to the tail base (length), from the floor to back (height), from udder to back (depth), and across the front shoulders (width) using a measuring tape, calipers, and spirit level. Sows were in farrowing crates 1-2 days prior to farrowing. Data were analysed across parity and between farms to assess trends in size. The data were compared to sow body dimension data collected in 2005. Among all sows sampled, body dimensions ranged from 154cm to 205cm (length), 75cm to 105cm (height), 52cm to 78cm (depth), and 28cm to 49cm (width). Across parity, body dimensions followed the expected pattern. As the sows got older there was a significantly increase ($p < 0.05$) up to parity 5, but an unexpected small decrease in size was present in all dimensions at parity 6. In contrast, the earlier findings showed Irish sows continuing to grow in height, depth, and width up to parity 8. Between farms, variation was observed in mature sow (parity 5+) size in dimensions of height ($p < 0.001$) and width ($p <0.01$). For each dimension, at least one farm had significantly larger mature sows compared to the 2005 values ($p < 0.05$). The observed decline at parity 6 may reflect culling practices, where larger sows are preferentially removed or more susceptible to lesions/locomotion issues, reducing the representation of large sows in late parities. Variation between individual farms and 2005 sows may be due to differences in management, genetics, or culling selection strategies influencing sow body size outcomes. Sow body dimensions have increased since 2005, consideration of these changes is an important aspect of designing appropriate housing for the sow's needs.

Botanical supplementation: An effective Approach to manage tail biting in pigs farm

C. Maltret[1], S. Cisse[1], M. E. A. Benarbia[1], A. Roques[1]
[1] Nor Feed, 3 rue Amédéo Avogadro, 49070 Beaucouzé, France

Building resilient livestock systems may require new tools against welfare issue. Regarding the tail biting behavior, a multi-factorial issue, most of the currently identified solution requires medium- to long-term measures, like reducing density or working on air flow. In this context, liquid complementary feed can offer a short-term solution to preserve the system health before working on other measures. By their documented calming effect on animal's behavior, Melissa officinalis and magnesium are relevant to enter in such a solution. This study assessed the impact of a natural solution containing Melissa officinalis and magnesium supplementation used in reaction to tail biting and its effects on pigs' behavior under commercial conditions. After weaning at 28 days, piglets from a gilt-breeding farm were randomly allocated to either a supplemented (S, n=103) or a control (C, n=102) group in identical environments, under commercial conditions. To evaluate tail biting evolution inside of each group, and its consequences, all pig tails were graded once a week from week 7 to week 21. Supplementation started in reaction to fresh blood observation, the supplement (Care Zen) was added to the drinking water (1 L/1000 L) for a 5-day period. The choice of a reactive approach was done to get close to real farm management practices. Tail grades between groups were compared using a Chi-square test with pig as a statistical unit. For behavioral analysis, in both rooms, one pen was video-recorded at three different periods for 3 consecutive days. The videos were analyzed using the scan sampling method to assess tail biting, resting, exploring, and feeding behaviors. Each scanned hour was defined as an observation period (OP), and was the statistical unit for behavioral analysis. In total, 97 OP were analyzed. Principal component analysis and hierarchical ascending classification were used to objectively analyze behavioral data and create OP clusters defined by the prevalence of pig behaviors within each. Number of tail or ear biting events in each group were analyzed through a Fisher test, with OP as statistical unit. All assessments were carried out by a blinded evaluator. In total, two supplementation periods took place. On camera recordings, tail and ear biting observations per day were significantly lower for S (Fisher, p-value <0.05), with 0.44 +/-1 events than in group C with 13.74+/- 10 (mean ± SD) events per day representing a 96.8% reduction in biting events. From video observations, three OP groups were identified based on behavior: Low, Medium, and High activity hours. The C group contained all (14/14) High activity OP with more aggressive behaviors (Dunn, p-value < 0.05), while the S group included more (79%, 19/24 in S) Low activity OP. Medium activity OP appeared equally (10/22 in S) in both groups and are mainly linked to feeding times or non-aggressive playful activities. These results show that a reactive supplementation with a standardized botanical product may contribute to reducing tail biting and its severity and induce a calmer atmosphere on farms. We thank Alexis Nalovic (Epidalis, Vitré, France) for identifying the study farm and for providing technical support throughout the study, allowing the evaluator to remain blinded.

Ex vivo antimicrobial assay determines in vivo antibacterial activity of glycerides of lauric acid against S. suis

O. Lemâle[1], T. Meyns[1], A. Mellouk[1], N. Vieco-Saiz[1], M. Jlali[1], J. Consuegra[1]
[1] Adisseo France S.A.S., European Laboratory of Innovation, Science & Expertise (ELISE), 20 rue Prosper Monnet, 69190 Saint Fons, France

Antibiotic resistance is an increasing threat, making alternative strategies essential for controlling pathogens such as Streptococcus suis in pigs. We developed an ex vivo antimicrobial assay using digestive fluids from animals supplemented with glycerides of lauric acid (GC12). We hypothesized that digestive fluids from piglets receiving GC12 would exhibit higher antibacterial activity against S. suis compared to digestive fluids from non-supplemented piglets. Twelve weaned piglets of 24 days of age were equally divided into two groups. A control group received a commercial diet adequate in all nutrients, and the treatment group received the same commercial diet supplemented with GC12 (FRA® C12 Dry) at 4 and 3 kg/ton of feed from 0 to 11 days and from 12 to 50 days, respectively. At day 50, all piglets were euthanized by an intracardial overdose of sodium pentobarbital 20% until cardiac arrest, after intramuscular sedation with a mixture of xylazine, tiletamine and zolazepam (XylM 2% + Zoletil 100) at a dose of 0.22 mL/kg bodyweight. Digesta samples were then collected in Falcon 50 ml tubes from the ileum, distal colon, and rectum. Digestive fluids were extracted by centrifugation and filtration with 0.22µm filters and then subjected to MIC analysis to determine antibacterial activity against S. suis CRBG BB-3 serotype 7 in a 1:1 dilution with the bacterial culture. Fisher's Exact Test (one-sided) was used to analyze statistical differences of the binary outcomes (0 = growth, 1 = inhibition) from the control and treatment group. Antibacterial activity was observed in 17% of the digestive fluid samples collected from both the ileum and distal colon of the control piglets. Rectal samples showed higher activity with 40% of the samples having inhibitory effect on S. suis. In GC12-supplemented piglets, significantly higher inhibition ($P = 0.04$) was observed in the ileum as compared to the control group, with 83% of the samples showing antibacterial activity. In the distal colon, S. suis inhibition was obtained in 67% of the samples ($P = 0.12$) and 60% of the rectal samples ($P = 0.50$). Previous studies have already demonstrated in vitro antibacterial activity against S. suis, however, determining the effective dose level in vivo based on minimum inhibitory concentration (MIC) values is challenging, as multiple physiological processes including, digestion, absorption and microbial interactions, can substantially modify the bioavailability and activity of the compound. Therefore, we developed this ex vivo antimicrobial assay using digestive fluids from animals supplemented with the feed additive. Indeed, the digestive fluids from piglets receiving the recommended dose level of GC12 showed higher antibacterial activity against S. Suis compared to digestive fluids from non-supplemented piglets with the most pronounced effect observed in the ileum, a key segment of the intestine where immature immunity, high nutrient availability, and epithelial vulnerability can facilitate early bacterial translocation and systemic dissemination. Hence, our findings align with previous MIC data, proof that the in vivo dose level is effective and supports the hypothesis that GC12 supplementation can contribute to mitigation of bacterial challenges as S. suis in vivo. The lack of significant difference in distal colon and rectal samples may reflect the limited number of replicates or inherent variability in antimicrobial activity along the intestinal tract. A follow up study should further assess if rectal samples can serve as a reliable matrix for evaluating the ex vivo antimicrobial effect of feed additives.

Plasma lipid dynamics during traditional acorn-based fattening in culled Iberian sows

J. García-Gudiño[1,2], C. Barraso[2], I. Blanco-Penedo[3], M. López-Parra[2], M. Izquierdo[2], F. I. Hernández-García[2]
[1] University of Extremadura, Animal Production and Food Science, Avenida de la Universidad s/n, 10003 Cáceres, Spain, [2] Centre of Scientific and Technological Research of Extremadura, A-V km 372, 06187 Guadajira, Spain, [3] University of Lleida, Department of Animal Sciences, Av. de l'Alcalde Rovira Roure,191, 25918 Lleida, Spain

The montanera fattening system, based on free-range grazing of acorns and grass in the dehesa ecosystem, is a traditional extensive production model for high-quality Iberian pig products. It offers a sustainable strategy by economically valuing culled sows within a circular economy framework. Although effects of acorn-based diets on meat quality, particularly intramuscular fat content and fatty acid profile, have been documented, the associated metabolic responses in blood lipid during this fattening phase are not yet fully characterised. Understanding these physiological changes in entire culled sows is essential to explaining the biological basis of high-quality meat production. This study aimed to evaluate plasma lipid profile dynamics during a 60-day montanera fattening period in culled Iberian sows. A total of 18 culled Iberian sows (initial body weight 162.4 ± 3.29 kg) were studied during traditional montanera. All animals were entire (non-castrated) to avoid hormonal confounding factors. Blood samples were collected at the beginning and end of the fattening period. Plasma was analysed for high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), total cholesterol, triglycerides, glucose, and urea. Acorns from Quercus ilex, the predominant food source, contain high starch (50-60%) and low protein (4-6%), with lipids rich in unsaturated fatty acids, particularly oleic acid (>60%). Animals reached a final body weight of 203.8 ± 3.25 kg, with backfat thickness measured by ultrasound increasing from 3.09 ± 0.21 to 4.92 ± 0.29 cm. The montanera phase induced profound shifts in lipid metabolism. HDL cholesterol increased from 49.6 ± 10.0 to 82.4 ± 15.7 mg/dL (P=0.016), a 66% elevation. Total cholesterol increased from 112.1 ± 22.5 to 159.7 ± 31.6 mg/dL (P=0.017), representing a 42% rise. Most remarkably, triglycerides increased by 139%, from 82.2 ± 35.5 to 196.7 ± 70.9 mg/dL (P<0.001). Glucose increased from 71.9 ± 5.9 to 90.7 ± 8.8 mg/dL (P=0.001). In comparison, urea substantially decreased from 31.5 ± 6.0 to 12.8 ± 6.0 mg/dL (P<0.001), a 59% reduction suggesting efficient utilisation of acorn-derived lipids and carbohydrates as primary energy sources, with reduced reliance on protein catabolism. These results demonstrate that traditional acorn-based fattening promotes major lipid metabolism adaptations in entire culled sows, characterised by substantial elevations in circulating lipoproteins and triglycerides. The marked increase in HDL cholesterol alongside a substantial elevation in triglyceride reflects a metabolic response to an acorn-based diet rich in unsaturated fatty acids. Concurrent backfat thickness gains and substantial urea reduction indicate efficient nutrient partitioning towards lipid deposition rather than protein degradation. These physiological changes provide the foundation for understanding the characteristic intramuscular fat infiltration and favourable fatty acid composition that define montanera-finished Iberian pig products. This work contributes to characterising plasma lipid dynamics during montanera fattening in culled Iberian sows, providing insights into the metabolic foundation of this traditional production system and supporting the valorisation of culled Iberian sows.

Implementing new legal requirements for sow housing: factors influencing functional use of an outdoor area in the mating area

S. Geisler[1], M. Hasler[2], A. L. Van Asten[3], N. Kemper[4], I. Traulsen[1]
[1] Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [2] Christian-Albrechts-University Kiel, Applied Statistics, Ludewig-Meyn-Straße 9, 24118 Kiel, Germany, [3] Chamber of Agriculture of North Rhine-Westphalia, Centre for Agriculture Haus Düsse, Ostinghausen, 59505 Bad Sassendorf, Germany, [4] University of Veterinary Medicine Hannover, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Germany, Bischofsholer Damm 15, 30173 Hannover, Germany

In response to the European Commission's 2021 initiative to phase out permanent confinement, legislative reforms in Germany will require group housing with short-term fixation and at least 5 m2 per sow in the mating area by 2029. This transition presents structural and management challenges, particularly during the critical post-weaning phase characterised by social reorganisation and oestrus activity. Integrating an outdoor area offers a practical approach to increase functional space and enhance welfare. However, evidence-based design requires a detailed understanding of utilisation patterns and influencing factors. Therefore, the use of an outdoor area was investigated under commercial farm conditions. A total of 85 sows were observed on 14 selected observation days between March and August 2023, with a focus on the first four days after weaning (day 0–3). Outdoor presence and resting behaviour were recorded at 10-minute intervals using video analysis. Environmental parameters, a heat stress index, and group composition were analysed using generalised linear mixed models. Outdoor area use showed a clear diurnal pattern ($P < 0.001$), with peaks shortly after the morning feeding and in the afternoon. On average, 32.7% ± 14.0% of sows were outdoors. During periods of low overall outdoor presence, particularly at night, most sows present were resting, whereas during peak activity in the morning, resting decreased sharply, indicating a functional shift from resting to activity and social interaction. Social dynamics influenced early post-weaning use ($P < 0.05$). Outdoor presence was highest on day 0, while resting was minimal, reflecting exploratory behaviour and hierarchy establishment. In subsequent days, presence decreased and resting increased, indicating progressive social stabilisation, with a renewed increase in outdoor presence on day 3, linked to oestrus activity. Greater parity variation within groups reduced outdoor presence ($P < 0.001$), suggesting that social heterogeneity may limit equal access. Environmental factors significantly modulated use patterns. Precipitation consistently reduced both presence ($P < 0.001$) and resting behaviour ($P < 0.05$), while solar radiation promoted outdoor presence ($P < 0.001$). Higher thermal load decreased both outdoor presence and resting behaviour ($P < 0.001$). Overall, the outdoor area was used dynamically as a social, active, and resting space. Effective design should consider temporal functional shifts, conflict-reducing spatial structuring, and protection against adverse weather. These design considerations facilitate the practical implementation of the 5 m2 space requirement in group-housed mating systems. This work is financially funded by the Federal Ministry of Agriculture, Food and Regional Identity (BMLEH) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE; grant number: 28N305603).

Behaviour of fattening pigs in structured pens with outdoor access

A. L. Ehrlich[1], A. Langehennig-Peristenidou[1], N. Kemper[1], T. J. Nicolaisen[1]
[1] University of Veterinary Medicine Hannover, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15 - Gebäude 116, 30173 Hannover, Germany

Due to climate change and the increasing emphasis on animal welfare, German pig housing systems are undergoing substantial transformation. Structured pen designs are gaining popularity because they can better accommodate pigs' behavioral and physiological needs by providing distinct functional areas. This study investigated the use of a structured pen with outdoor area at different times of day. The study was conducted on a commercial farm in Germany from March to September 2025. A total of 168 pigs (Topigs x Duroc) kept in two structured pens were examined over the course of two batches. Each pen was divided into functional areas, including two separate lying areas, a slatted floor area and an outdoor run with straw bedding. Temperature and humidity were continuously monitored using data loggers. Video recordings were analyzed using a scan sampling approach: The use of the different functional areas was assessed for a full day once per week. For this purpose, the number of pigs located in the outdoor run, lying area and on the slatted floor was counted on day (8AM, 10AM, 12AM, 14 PM, 16PM) and at night (8PM, 10PM, 2AM, 4AM). Additionally, the body positions prone, lateral, standing, and sitting were recorded. The data were descriptively described. The mean number of pigs differed between functional areas and between day and night periods. During the night, pigs were mainly located in the outdoor area (mean and standard deviation: 16.1 ± 33.1 pigs) and in the lying area (10.3 ± 19.8 pigs), whereas fewer animals were observed in the slatted floor area (3.9 ± 7.7 pigs). During the day, most pigs were found outside (23.3 ± 25.8 pigs). Comparable numbers of pigs were present in the indoor areas, with 9.0 ± 10.1 pigs in the lying area and 9.0 ± 8.6 pigs in the slatted floor area. The mean number of pigs exhibiting different body postures varied between day and night periods. Outside, lateral lying was the predominant posture during both time periods, with 56.8 ± 29.5 pigs lying laterally during daytime (06:00–16:00) and 60.4 ± 42.1 pigs during nighttime (18:00–04:00). In contrast, standing outside occurred significantly more frequently during the day (17.4 ± 8.5 pigs) than during the night (1.5 ± 1.9 pigs). The outdoor run was well accepted by pigs throughout the entire day in the analysed warm period, indicating successful integration into the housing system independent of time of day. Pigs used the outdoor area for both resting and active behaviors, demonstrating its function as a multifunctional space rather than solely an activity zone. Frequent lateral lying suggests that animals perceived the outdoor environment as comfortable and suitable for undisturbed rest, while increased standing behavior during daytime reflects active exploration and interaction with the provided straw as environmental enrichment. Continuous use of the outdoor run highlights its relevance for supporting natural behavioral expression and promoting animal welfare. Overall, structured pens improve pig welfare by offering a range of functional areas allowing behavioral flexibility. This research is part of the ZERN (Future Nutrition Lower Saxony) network and was funded by the Lower Saxony Ministry for Science and Culture (MWK) and the Volkswagen Foundation within the programme zukunft.niedersachsen.

Effects of different nesting materials on crushing risk and sow posture changes in a temporarily confined farrowing system

J. Wahmhoff[1], M. Wutke[1], A. L. Van Asten[2], N. Kemper[3], I. Traulsen[1]
[1] Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [2] Chamber of Agriculture of North Rhine-Westphalia, Centre for Agriculture Haus Düsse, Ostinghausen, 59505 Bad Sassendorf, Germany, [3] University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany

The provision of nesting material is regarded as an important measure to support pre-parturient behavior in sows. However, under commercial conditions its practical implementation remains limited, partly due to practical concerns such as the potential negative effects on manure systems and additional labor requirements. The present study evaluated the impact of different organic nesting materials on crushing risk and sow activity in conventional farrowing systems with short-term crating. At the same time, the aim was to generate practice-oriented evidence in line with current animal welfare regulations, to address existing practical reservations. In this study, a total of 263 farrowings from 141 sows were included. Each sow was randomly assigned to one of three treatments: grass hay, long-stemmed straw, or a jute bag serving as minimal enrichment control. Nesting material removal from the racks was recorded daily from day 112 of gestation until farrowing. Crushing losses were documented during the first three days postpartum. In addition, sow activity during the first 72 h after farrowing was quantified using automated video-based analysis, with posture changes (transitions between standing and lying) serving as an objective indicator. Although considerable inter-individual variation occurred, no significant differences in pre-partum material usage during the two days prior to farrowing were detected between hay and straw (means: 417 g vs. 354 g). Crushing losses within the first three days after birth were lowest in the straw group (3.51 %), followed by hay (4.68 %) and the jute bag group (6.52 %). Statistical analysis showed 46 % lower odds of crushing in the straw group compared to jute bag control, whereas the hay group showed no significant differences to the jute bag treatment. Sows provided with straw exhibited significantly fewer posture changes (median 128) than sows from the jute bag control (median 160), corresponding to a reduction of approximately 28 %. A moderate positive correlation ($\rho = 0.40$) was observed between posture change frequency and crushing losses during the first three days postpartum. The results demonstrate that not only the provision but also the functional properties of nesting material are relevant. Long-stemmed straw reduced sow activity during the critical early postpartum phase and significantly decreased crushing risk. Furthermore, the small quantities of used material in this study are unlikely to interfere with manure systems. Thus, even in conventional systems with partially slatted floors and temporary crating, structured nesting material represents a practical and feasible management strategy to improve sow and piglet welfare. This work is funded by the German Federal Ministry of Agriculture, Food and Regional Identity (BMLEH) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE). Does the temperature-humidity index affect the growth rate of weaner pigs?

J. Probst[1], P. Heseker[1], C. Meyer[1], S. Götz[1], S. Schäfers[1], I. Traulsen[2], N. Dirksen[3], N. Kemper[1]
[1] University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany, [2] Christian-Albrecht-University of Kiel, Institute for Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [3] Chamber of Agriculture Lower Saxony, Hermann-Ehlers-Straße 15, 26160 Bad Zwischenahn, Germany

Measuring pigs´ individual body weight via automatic 3D-image-processing is valuable for analysing the weight distribution within a pen or batch and for assessing weight gain without the stressful and time-consuming procedure of manual individual weighing. This study investigated whether any impact of the temperature-humidity index (THI) is reflected in automatically generated data on weekly weight gains of individual weaner pigs. Seven batches of weaner pigs (n=1,446) with RFID-ear tags housed in one compartment with six pens, equipped with climate sensors (DOL 114, dol-sensors A/S, Aarhus, Denmark), were included in this study. Modified drinking stations with RFID-antennas and 3D-cameras (OptiTrack, Hölscher + Leuschner, Emsbüren, Germany) automatically assigned the RFID-number to the estimated optical weight (EOW) continuously. During the six weeks of rearing, the mean weekly THI (wTHI) was calculated from the recorded climate data according to De Prekel et al. (2024), and EOW were summarized weekly by using the mean weight (mEOW) for the specific period. After excluding implausible weights (<5 and >40 kg), the percentage increase between the individual weights of consecutive weeks was used to calculate relative weekly gains (rWG). A spearman correlation (ρ) between the rWG and wTHI was calculated for each rearing week (1-6). The wTHI values recorded over all batches and weeks ranged from 71.9 to 82.2, with an average of 77.1. From week 1 to 2 ($\rho = -0.058$, $p = < 0.001$, $n = 5{,}982$), 2 to 3 ($\rho = -0.146$, $p < 0.001$, $n = 5{,}964$) and 5 to 6 ($\rho = -0.119$, $p < 0.001$, $n = 5{,}778$), there were highly significant, but very weak to negligible, negative correlations between rWG and wTHI. There was no significant correlation in weeks 3 to 4 ($\rho = 0.019$, $p = 0.144$, $n = 5{,}970$), and a negligible positive influence in weeks 4 to 5 ($\rho = 0.069$, $p < 0.001$, $n = 5{,}898$). A clear influence of the THI on individual relative weekly weight gains in weaner pigs was not demonstrated based on optical weight measurements. Since multifactorial influences (e.g. genetics, feed, health status, animal welfare) can affect growth rates and heat stress-resilience as well, further research is needed to evaluate the effect of elevated THI-values in the different growth phases of pigs more precisely. The project was supported by funds of the Federal Ministry of Agriculture, Food and Regional Identity (BMLEH) based on a decision of the Parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food (BLE) under the strategy for digitalisation in agriculture, grant number 28DE109E18.

Bone mineral content kinetics in sows across three consecutive lactations as a function of dietary phosphorus during lactation

J. Heurtault[1], M. P. Létourneau-Montminy[2], P. Schlegel[1]
[1] Agroscope, Route de la Tioleyre 4, 1725 Posieux, Switzerland, [2] Université Laval, 2425 Rue de l'Agriculture, QCG1V0A6 Québec, Canada

Recent data indicate that sows mobilize bone mineral reserves during lactation to meet their calcium (Ca) and phosphorus (P) requirements and subsequently restore these reserves during the following gestation. The mobilization of these reserves is further increased when dietary Ca and P supply is reduced. However, the resilience in bone mobilization-restoration of sows subjected to a low-P lactation diet over consecutive cycles, remains unknown. The objective of the present study was to address this question. A total of 28 primiparous Swiss Large White sows from the Agroscope herd were selected and assigned to four lactation diets formulated to meet the recommended nutrient requirements except for digestible P and Ca: 100 met 100% of the requirement, without exogenous phytase (9.0 g Ca, 3.0 g digestible P/kg, and a 3:1 Ca/digestible P ratio; 8 sows); 50 met 50% of the requirement, without exogenous phytase (4.5 g Ca, 1.5 g digestible P/kg, and a 3:1 Ca/digestible P ratio; 8 sows); 100+FTU (6 sows) and 50+FTU (6 sows) where 100 and 50, were respectively, supplemented with an exogenous phytase (750 FTU/kg, Quantum® Blue 5G, AB Vista, Marlborough, United Kingdom). Sows were fed ad libitum during the lactation. The gestation diet was formulated to cover nutritional requirements and did not contain exogenous phytase. Feed allowance was set at 2.8 kg/day during the first 80 days of gestation and increased to 3.0 kg/day thereafter. Sows were scanned by dual-energy X-ray absorptiometry (DXA) for bone mineral content (BMC, g) and fat tissue mass (kg) over three consecutive lactations (Lact1, Lact2, Lact3) at 2 (d2) and 24 days (d24) postpartum, and during the second gestation (Gest2) at day 40 (d40). The BMC was analyzed using a mixed model including stage (time point of measurement), lactation diet, and their interaction, with a Corsymm residual covariance structure. The mobilized BMC (BMCd24 – BMCd2) within lactation was analyzed using a mixed model including lactation number, lactation diet, and their interaction. In both models, the sow was included as a random effect. A linear correlation between mobilized BMC and fat tissue was performed across the diets 100+FTU, 100, and 50+FTU. On d24 of Lact1, BMC tended to be lower in 50 than in 100+FTU ($P = 0.054$), and on d24 of Lact2 and Lact3, it was lower than in both 100 and 100+FTU ($P < 0.05$). BMC did not differ between treatments at the other stages. The mobilized amount of BMC during lactation did not differ between treatments across lactations. These results confirm that sows fed a low-P diet during lactation mobilized more BMC, and showed that the mobilized BMC was restored over two consecutive gestations. The sow therefore appears to be resilient to a low dietary P supply over several consecutive cycles. The mobilized BMC was linearly associated with the mobilized fat tissue mass ($R^2 = 0.72$, $P < 0.001$). These findings show that during a period of higher metabolic intensity sows mobilize energy from fat tissue and minerals from bone to meet the nutrient demand for milk production. This relationship provides new perspectives for estimating mineral mobilization.

Inter-rater reliability of animal-based indicators intended for organic inspections on pig farms

S. Lühken[1], A. Höhne[1], A. Schubbert[1]
[1] Friedrich-Loeffler-Institut, Institute of Animal Welfare and Animal Husbandry, Dörnbergstraße 25/27, 29223 Celle, Germany

Inspections on organic farms must be reliable, and different inspectors should reach the same conclusions when assessing animal welfare. Therefore, animal-based indicators used in inspections need to show a high inter-rater reliability to ensure consistent and comparable results. In the ÖKoTier project, a standardized inspection concept for the annual animal welfare inspection on organic farms is being developed. After selecting suitable animal-based indicators for pigs, the inter-rater reliability was examined in pre-tests between two scientists using photos and videos and subsequently in practice on a sample of sows, suckling piglets, weaned piglets, and fattening pigs. The proportion of agreement, the prevalence-adjusted bias-adjusted kappa (PABAK), the prevalence index (PI) and bias index (BI), and a McNemar test were calculated in R 4.4.1 for the two-score level indicators lameness, manure on the body, tail lesions, ear lesions, skin lesions on the head and carpal joints in suckling piglets, bursitis, body condition score, runts, and hospital pigs. Since the photos and videos were selected based on the criterion that both score levels were evenly distributed, the prevalence effect on these tests was low (PI: median: 0, min: -0.15, max: 0.15). In contrast, the prevalence effect was evident in practice where score 0 generally occurs more frequently than score 1 (PI: median: 0.91, min: -0,24, max: 1). Median PABAK of all indicators tested with photo and video material was 0.9 (min: 0.7, max: 1) and 0.97 (min: 0.52, max: 1) in practice. For indicators with PABAK < 0.81 (manure on the body, skin lesions on the head and carpal joints, runts), an error analysis was performed based on differently rated photos and videos. In addition, systematic differences between the raters were examined using the results of BI (photos and videos: median: 0, min: -0.05, max: 0.06; practice: median: 0, min: -0.11, max: 0.12) and McNemar tests. However, the latter was only significant in practice for the indicator runts in weaned piglets. These results were discussed among the raters, after which some indicator methods were simplified or supplemented with additional information. Subsequently, the inter-rater reliability for these indicators was retested, reaching a good reliability for all indicators in practice (PABAK ≥ 0.8). By testing inter-rater reliability using photos and videos in addition to practical tests, potential prevalence effects can be mitigated. This, together with the calculation of several reliability parameters, enables a comprehensive problem analysis and interpretation of results in order to improve reliability in practice.

Turning Carasau bread leftovers into piglet gains: performance and diarrhoea outcomes after full wheat replacement in the diet

G. Bee[1], R. Ruggeri[1], A. Loddo[4], P. Catzeddu[3], T. Roggio[3], G. Battacone[2]
[1] Agroscope, Pig Research Unit, Rte de la Tioleyre 4,, 1725 Posieux, Switzerland, [2] University of Sassari, Agricultural Sciences, viale Italia 39a, 07100 Sassari, Italy, [3] Porto Conte Ricerche, Loc. Tramariglio, 07041 Alghero, Italy, [4] MFM Sunalle,, via Ogliastra 10, 08023 Fonni (NU), Italy

Sustainability in pig production increasingly depends on improving feed resource efficiency and reducing competition with human-edible ingredients. Circular feeding strategies, valorizing food industry by-products as feed, can contribute to this goal by reducing food waste. The bakery sector generates substantial waste streams, and bread leftovers may offer an alternative to conventional cereals such as wheat in pig diets. However, baking alters starch structure and may influence digestibility, metabolic responses, and diet consistency, which is particularly relevant in the sensitive post-weaning period. This study evaluated whether complete replacement of dietary wheat with flour from Sardinian carasau bread leftovers affects post-weaning piglet performance and health. In a feeding trial, 100 piglets (females and barrows) from 9 sows were used. Piglets from 5 sows were assigned to the control diet (C), a conventional post-weaning diet formulated according to Swiss recommendations (Agroscope, 2025) containing up to 30% wheat, and piglets from 4 sows to the Bread diet (B), in which the wheat fraction of diet C was fully replaced by carasau bread leftover flour. From 21 days of age, piglets had ad libitum access to their assigned feed (creep feed), and after weaning they were allocated to 9 pens per treatment (6-7 pigs/pen), balancing sex ratio as far as possible. Growth and feed intake were monitored up to 7 weeks post-weaning, and diarrhea occurrence was recorded. Mixed-effects models were used for repeated measures on body weight (BW) and average daily gain (ADG), pen-level feed intake, and a binomial model for diarrhea probability. The BW were similar early post-weaning but diverged over time (diet × time, $P < 0.01$), with C pigs being heavier at week 7 than B pigs (27.6 vs. 25.6 kg). Weekly ADG showed a significant diet × week interaction ($P < 0.01$), and overall ADG was slightly higher in C than B (0.41 vs. 0.37 kg/d; $P = 0.04$). Feed intake differed from week 4 onward (diet × time, $P < 0.01$), resulting in lower total intake in B than C (28.9 vs. 33.3 kg/pig; $P < 0.01$) alongside a modest improvement in gain-to-feed ratio for B (0.63 vs. 0.59; $P = 0.05$). Importantly, the B diet reduced the probability of diarrhea compared with the Control ($P < 0.01$). Overall, replacing wheat with carasau bread leftovers supported acceptable post-weaning performance, improved feed efficiency, and lowered diarrhea risk, though with a small reduction in final BW. These findings provide evidence to support bakery by-products as a practical component of circular feeding systems in pig production, while highlighting performance trade-offs that should be considered when implementing full cereal replacement strategies. This work was funded by Ministero delle Imprese e del Made in Italy, Fondo per la Crescita Sostenibile – Accordi per l'innovazione di cui al D.M. 31 dicembre. Project n. F/310035/01-04/X56 "Tecnologie ICT e dell'Industria 4.0 per l'analisi e l'ingegnerizzazione di Sistemi alimentari complessi per la produzione di pani artigianali locali ad alto valore aggiunto (AISAC)

Detection and monitoring of several salivary heat stress biomarkers in growing pigs

C. Puigfel-Camarasa[1], L. Sarri[1], G. De La Fuente[1], M. Tor[1], A. R. Seradj[1], J. Balcells[1]
[1] Universitat de Lleida - AGROTECNIO-CERCA, Ciència Animal, Av. Alcalde Rovira Roure 191, 25198 Lleida, Spain

Thermal stress (TS) is one of the main challenges for the pig industry, as it negatively affects animal welfare and productive performance. Its assessment through plasma biomarkers can provide a consistent and objective tool for its detection and correction. However, plasma sampling requires blood extraction, which is inherently stressful. The objective of the present approach was to detect in saliva heat stress-indicators, as alternative biological fluid. Fifteen pigs (Pietrain-Yorkshire x Duroc-Landrance; 35 kg LW) were used and distributed into 3 pens (5 pigs each). After a 7-day adaptation period, animals were subjected to the following environmental conditions in consecutive 7-day periods: Thermal Neutrality (≈23ºC, ≈34% temperature and relative humidity (RH), respectively), TS (≈33ºC, ≈36% RH) and a return to Thermal Neutrality. Rectal temperature was measured every 48 h. Saliva samples were taken on day 7, 14 and 21 of the experimental period. Pig weight, feed intake, and water consumption were daily recorded. Saliva collection was designed to cause minimal disturbance. Disposable sponge held by Kocher forceps were introduced into the pig's mouth and allowed to be chewed. Once saturates with saliva, the sponge was removed and placed in Salivette® vial (Sarstedt, Ref. 51.1534, Germany) and immediately centrifuged (2.500 rpm, 10 min). The analysed biomarker included acute phase proteins (Haptoglobin, Serum amyloid A, C-reactive protein, Apolipoprotein A1, Chromogramin A and Pig-MAP). Specific proteotypic peptides were used as markers for each protein. The proteotypic peptides were analysed by a UPLC-SRM/MS system. Pig performance showed no major residual variability throughout the experimental period compared with standards defined for this breed and age. However, thermal stress significantly reduced dry matter intake and growth performance ($P<0.05$), while water consumption significantly increased (up to 30 %, $P<0.05$) during the hyperthermic phase. Rectal temperature during thermal Neutrality (39.07± 0.30 $_{o}$C) increased significantly under hyperthermia (39.36 ± 0.32 $_{o}$C) and returned to baseline values during the recovery phase (39.02± 0.28$_{o}$C). This may indicate that young pigs were unable to fully adapt to the imposed heat conditions. Regarding salivary biomarkers, Pig-MAP, Chromogramin A and Haptoglobin were not detected in saliva samples, possibly because their concentrations were below the detection limit or because salivary glands may act as a physiological filter for these proteins. In contrast, Apolipoprotein A1 and serum amyloid A were consistently detected in saliva, with concentrations clearly above the detection limit in our UPLC-SRM/MS (in the order of µg/mL). Moreover, a significant reduction in Apolipoprotein A1 (and a trend for serum amyloid A) was observed during hyperthermia, followed by partial recovery after returning to thermal neutrality, although without fully reaching the initial baseline values. C-reactive protein was also consistently detected in saliva across all thermal phases, with concentrations above the detection limit; however salivary C-reactive protein levels remained constant regardless of thermal condition ($P>0.05$). Saliva concentration of the tested biomarker seems to be less sensitive than plasma although the moderate intensity and short duration of the thermal challenge may not have been enough to trigger a marked acute phase response. Additionally, residual variability associated with the sample collection and saliva composition may have introduced biological noise, limiting the statistical significance of some observed differences.

From heat stress to genetic resilience: addressing seasonal infertility in Pigs

L. Bordin Temp[1], N. Galoro Leite[2], L. Zak[2], J. Linck Moroni[2], J. M. Tabet[2], E. Grindflek[2], D. Lourenco[1]
[1] University of Georgia, Animal and Dairy Science, 425 River Rd, 30606 Athens, United States, [2] Topigs Norsvin, Research Center, Meerendonkweg 25, 5216 TZ 's-Hertogenbosch, Netherlands

Seasonal fluctuations in environmental conditions, particularly elevated temperatures, present significant constraints to pig production globally. Heat stress adversely affects animal welfare, increases disease susceptibility, and induces endocrine and metabolic disruptions that impair reproductive performance. Due to pigs' limited capacity to dissipate metabolic heat, production losses occur even in facilities equipped with cooling systems. Reproductive traits are especially vulnerable, with heat stress linked to delayed puberty, reduced estrus expression, lower farrowing rates, increased pregnancy loss, and smaller litter sizes, a phenomenon commonly referred to as seasonal infertility. Considerable variation in response to heat stress among animals suggests the presence of genetic differences in tolerance or susceptibility, indicating that seasonal infertility may have a heritable component and could potentially be mitigated through selective breeding. However, the extent of this genetic contribution and the most suitable statistical framework to capture genotype-by-environment (G×E) interactions and environmental sensitivity remain uncertain. Canadian (N = 391,275) and Brazilian (N = 544,865) datasets will be analyzed to represent contrasting climatic conditions (temperate vs. tropical) from 2016 to 2025. The study includes two purebred maternal lines (L1 and L2), enabling the evaluation of animals across distinct environmental gradients. Evaluated traits will include total number born, total number of stillborn, farrowing rate, and gestation length. Preliminary population statistics showed differences in maternal lines across countries and seasons. In Canada, reproductive performance for L1 was slightly lower in summer than in winter, with fewer total born (13.92 vs. 14.08), fewer stillborn (0.96 vs. 1.03), and a shorter gestation length (117.5 vs. 118.1 days). Farrowing rate remained stable (99.29% vs. 99.23%). For Line L2, seasonal variation was minimal in total born (15.27 vs. 15.86), stillborn (1.28 vs. 1.32), and gestation length (115.3 vs. 115.4 days), though farrowing rate was slightly lower in summer (98.05% vs. 99.43%). In Brazil, both lines showed high seasonal stability. Line L1 had minimal variation in total born (14.28 vs. 14.29), stillborn (0.74 vs. 0.70), and gestation length (115.9 days), with a slightly lower farrowing rate in winter (99.82% vs. 99.98%). Line L2 remained consistent across seasons for total born (15.13 vs. 15.14), stillborn (0.99 vs. 0.98), and gestation length (114.5 vs. 114.6 days), with identical farrowing rates (99.9%). It is hypothesized that variation in seasonal infertility also has a measurable genetic component and that selection for greater robustness, as reflected by improved mean performance and reduced environmental variability under heat stress, is feasible. To test these hypotheses, random regression models across environmental gradients, multi-trait models across countries and gradients, and Double Hierarchical Generalized Linear Models will be compared to quantify environmental sensitivity and genetic heterogeneity of residual variance, and to determine which model best captures the influence of environmental factors. By integrating diverse statistical approaches and contrasting production environments, this study aims to clarify the genetic architecture underlying seasonal infertility and to evaluate the potential benefits of incorporating heat tolerance and robustness into commercial breeding programs, thereby supporting more sustainable pig production in the context of ongoing climate change.

Reframing sustainability for a fairer future for livestock farming: A One Welfare approach

L. Boyle[1], F. Johansen[1]
[1] Teagasc, Pig and Poultry Research and Knowledge Transfer, Fermoy, P61 C996 Cork, Ireland

One Welfare highlights the interconnections between animal and human welfare within their shared environment. Post-war agricultural development prioritised yield and cost (i.e. economic sustainability) at the expense of broader concerns. The three-pillar model (economic-social-environment) emerged to correct this imbalance. However, environmental sustainability is narrowly fixated on GHG emissions and technological solutions, sidelining other environmental issues (e.g. biodiversity loss), while social sustainability remains marginalised. Rising production costs and price volatility drive continued dominance of the economic pillar and with-it the continued externalisation of costs onto people, animals, and the environment, interconnected "One Welfare" burdens. This paper presents a case for re-framing sustainability around One Welfare to ensure a fairer future for livestock farming. We undertook an ad hoc review of the livestock sustainability literature to; 1) provide evidence of the conflicts and weaknesses of current frameworks, 2) an overview of overlap between economics and social sustainability and 3) to investigate an approach to sustainability that focuses on human and animal welfare underpinned by a healthy shared environment. We found that currently, animal welfare as part of the social pillar is almost entirely neglected and is sidelined when it conflicts with environmental objectives. There is growing acceptance that animal welfare should be considered separately. Ideally this would ensure that trade-offs, like when animal welfare conflicts with nitrogen use efficiency, are evaluated in a balanced manner. Nevertheless, despite human welfare being long represented by the social pillar, this dimension is consistently marginalised. for example, the healthiest diets for humans being seemingly carbon inefficient are eschewed in favour of plant based or highly processed meat alternatives (e.g. EAT-Lancet Commission report). This indicates that a dedicated pillar in the sustainability framework does not guaranty fair representation in the sustainability debate. There are calls for a conceptual sustainability framework based on integrity in which sustainability conflicts could be addressed by prioritising the welfare of humans and animals, as sentient beings, over non-sentient concerns (e.g. GHG emissions). The One Welfare concept of interdependence means that improving animal welfare leads to better human welfare, and vice versa, and that both rely on a healthy shared environment. Hence, non-sentient concerns would be addressed by default within holistic, often nature-based solutions rather than as singular technological solutions. Under economic sustainability, scale and efficiency are prioritised to the benefit of corporate players. Other sustainability frameworks position economics within the social pillar (e.g. FAO SAFA) ensuring that they have a higher human value (e.g. wages and prices) and are therefore economically fairer. This is akin to the One Welfare concept where economic benefits to society are outcomes of good human, animal and environmental welfare. Animal welfare requires a dedicated sustainability dimension to ensure the future of livestock production. Positioning economics within the social dimension requires it to serve human welfare, over corporate needs. Environmental sustainability remains crucial, but it should never trump the welfare of humans or animals (wild or domesticated) and within One Welfare it is protected by default. This reframing of sustainability using the One Welfare framework acknowledges that while there are trade-offs, putting sentience, and therefore the welfare of people and animals first, positioned within a shared healthy environment offers a fairer future for livestock farming.

Aggregation of indicators for the multifunctionality of mountain dairy cattle farms: a One Welfare approach

A. Zoratti[1], S. Bovolenta[1], E. Benedetti Del Rio[2], S. Sari[3], L. Bava[3], A. Tamburini[3], M. Berton[2], E. Sturaro[2], M. Corazzin[1]

[1] University of Udine, Department of Agricultural, Food, Environmental and Animal Sciences, Via delle Scienze 206, 33100 Udine, Italy, [2] University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment, Viale dell'Università 16, 35020 Legnaro, Italy, [3] University of Milano, Department of Agricultural and Environmental Sciences - Production, Landscape, Via Celoria 2, 20133 Milano, Italy

There is growing recognition of the need for integrated sustainability assessment tools that go beyond traditional environmental metrics to capture the complexity of livestock systems. The literature highlights the diversity of sustainability indicators proposed for dairy farms across the European Union and emphasises the importance of including animal welfare alongside agroecological, social, and environmental dimensions in order to support decision-making and policy development. Therefore, the objective was to develop a Multifunctionality sustainability Index (MInd) which aggregates multiple indicators to support the evaluation of mountain dairy farms' sustainability within a One Welfare approach. The study involved 20 mountain dairy farms and integrated 20 indicators encompassing animal welfare (W), agroecological (AE) and socio-territorial (ST) dimensions (based on IDEA4 farm sustainability indicators), as well as environmental impacts (I; based on Intergovernmental Panel on Climate Change). Data were collected through legal documents, the Italian Breeders Association, visual inspection and a questionnaire to farmers regarding all aspects of farm management. The MInd was built and then applied to farms. When several indicators exhibited high correlations (>0.8), an intermediate principal component analysis was conducted to select a single representative indicator. The MInd consisted of 9 key indicators in the final model, calculated as follow: MInd = + 0.011 * behaviour (W) + 0.385 * functional diversity (AE) + 0.227 * closed-loop material and energy flows in pursuit of autonomy (AE) + 0.390 * frugality in the use of resources (AE) + 0.340 * reduction of the impact on human health and ecosystems (AE) + 0.314* food production(ST) + 0.282 * local development and circular economy (ST) + 0.431 * employment and quality of work (ST) – 0.410 * ecotoxicity (I). MInd is mainly driven by employment and quality of work (0.431) and by ecotoxicity that showed a negative loading (−0.410), meaning that higher environmental impact reduces the index value. MInd successfully integrates all the initially intended dimensions and allows for differential weighting of each indicator, reflecting their relative contribution to overall sustainability. MInd offers a practical approach to monitor progress, identify strengths and weaknesses, and guide policies aimed at fostering sustainable and resilient dairy systems in mountain areas. This work was carried out within the project 'Looking for the agro-environmental friendly dairy farm: innovative approaches and integration of methodologies for an inclusive definition of sustainability in dairy systems', funded under the 2022 call by the European Union – NextGenerationEU.

Integrating Positive Animal Welfare and One Welfare: A Socio-Environmental Framework for Sustainable Livestock Systems

Farm animal welfare science has traditionally focused on preventing unnecessary suffering and mitigating negative affective states in animals. However, sustainable livestock systems require moving beyond deficit-based models toward approaches that actively promote positive experiences and account for broader socio-ecological dynamics. Positive Animal Welfare (PAW) emphasizes animals' positive affective states and experiences, whereas One Welfare highlights the interconnections between animal welfare, human wellbeing, environmental sustainability, and socio-economic viability. Despite increasing joint use, their conceptual integration remains insufficiently defined. We hypothesise that animals' opportunities to experience positive states, and the long-term sustainability of livestock systems, are systematically shaped by socio-ecological conditions at farm level, including management practices, human–animal interactions, labour conditions, environmental constraints, social acceptability, and economic profitability. Integrating PAW within a One Welfare approach could promote welfare improvements while positively impacting farm sustainability. This contribution, developed within the EU COST Action LIFT (Lifting Farm Animal Lives – laying the foundations for positive animal welfare, CA21124), aims to present an operational framework that aligns animal-based indicators of positive experiences (e.g. play, exploratory, affiliative behaviours and affect balance) with system-level variables. By combining fine-grained measures of individual experience with relational, system-level analysis, the framework may provide a scientific basis for linking measurable positive welfare states to the conditions that enable or constrain them. It may support the development of transferable, context-sensitive assessment tools and practical strategies that are socially acceptable and economically viable. Ultimately, this work will clarify the complementary roles of PAW and One Welfare, contributing to the embedding of positive welfare science within real-world livestock production systems.

Bringing animal welfare into sustainability: embedding animal wellbeing in Life Cycle Assessments

I. Kyriazakis[1], C. Wangui[1]
[1] Queen's University Belfast, School of Biological Sciences, 19 Chlorine Gardens, BT9 5DL Belfast, United Kingdom

Animal welfare is an essential but often underrepresented dimension of sustainability in livestock production. Although sustainability frameworks—including the United Nations Sustainable Development Goals and conventional Life Cycle Assessment (LCA)—address environmental, economic, and social aspects, they provide limited recognition of welfare outcomes within food systems. Given the close interconnections between welfare, environmental performance, human health, socio-economic performance and resilience, and societal acceptance, this study aims to articulate a coherent pathway for integrating animal welfare into holistic sustainability assessment. We identify conceptual and methodological gaps in current frameworks and proposes recognising animals as a distinct stakeholder group within Social Life Cycle Assessment (S-LCA). We outline a set of candidate activity variables suitable for quantifying welfare impacts, including time-in-condition, behavioural opportunity indicators, exposure to stressful interventions, health and vitality metrics, and cumulative welfare scores. A central methodological proposal is the use of "animal life days" as a scalable, functionally compatible activity variable that captures the duration animals spend in defined welfare states across production systems. This is equivalent to the notion of 'load', i.e. how long animals spend in the presence of a stressor. Adopting "animal life days" and related welfare metrics enables direct comparison of welfare outcomes across livestock systems and facilitates integration into established S-LCA impact pathways. The approach supports quantitative evaluation of welfare alongside environmental and socio-economic impacts, preserving the holistic intent of sustainability assessment. It also strengthens ethical coherence, enhances transparency in trade-off analysis, and aligns assessment practice with increasing societal expectations for responsible livestock production. We will provide a hypothetical example of how the concept of 'animal life days' would apply to the comparison between two systems that differ not only in the prevalence of welfare issues but also in the duration of exposure and the space available to each animal which determine likelihood of exposure. Embedding animal welfare within S-LCA provides a systematic and practical means to advance socially responsive, ethically grounded sustainability assessment in food systems. Recognising animals as stakeholders and operationalising welfare through measurable activity variables can support more credible decision-making for producers, integrators, policymakers, and consumers. Integrating welfare into existing LCA-based frameworks thus offers a pathway toward livestock systems that are not only environmentally efficient but also ethically and socially robust.

Development and on-farm implementation of a multidimensional sustainability assessment and benchmarking tool for pig and broiler production

L. Mertens[1], T. Van Daele[1], A. De Grande[1], E. Kowalski[1], E. Delezie[1], M. Aluwé[1]
[1] Flanders Research Institute for Agriculture, Fisheries and Food, Animal Sciences Unit, Burg. Van Gansberghelaan 119, 9090 Merelbeke-Melle, Belgium

Sustainable animal production is a multidimensional concept encompassing animal welfare, environmental impact, economic viability and social well-being. Despite increasing societal and policy attention, livestock farmers often lack clear insight into their overall sustainability performance. Most existing frameworks focus on a single sustainability aspect –typically economic and ecological impact– leaving animal welfare and social dimensions underrepresented. Given that improvements in one dimension can entail trade-offs in others, a holistic perspective is essential for informed decision-making. To address this gap, we aimed to develop a multidimensional sustainability assessment, information and benchmarking tool for pig and broiler production farms. The tool provides structured insight into farm performance across the 4 key sustainability pillars: animal health and welfare, environment, economy and social well-being. The online survey with automatic and personalized reporting was developed and evaluated in close collaboration with farmers, experts and stakeholders. Within each sustainability pillar, a set of carefully selected key performance indicators (KPIs) was defined, based on existing questionnaires and tools (e.g. AMCRA, Ruckli et al., 2022) as well as expert discussions. This resulted in 9 KPIs for animal health and welfare, 8 for environment, 9 for economy and 8 for social well-being. The survey entails 56 questions and takes between 30 to 90'. The report consists of 3 parts: 1) global overview figure of the two best and least scoring KPIs per sustainability pillar, 2) summary figure for each sustainability pillar presenting the scores of all KPIs, categorized into strengths and areas for improvement, for which recommendations are provided, and 3) more detailed information for all KPIs, including benchmarking across all participating farms. Rather than providing a weighted average that might mask underlying issues, the tool focuses on identifying specific strengths and critical points of attention for each farm. By evaluating the KPIs against predetermined reference values, relative scores are calculated. This results in a personalized report with targeted recommendations corresponding with those indicators requiring attention. Additionally, the tool fulfills a significant industry demand for benchmarking, allowing farmers to compare their results with peer groups, thereby providing an extra incentive for adoption. The applicability and suitability of the tool were evaluated through implementation on 33 pig farms and 23 broiler farms in Flanders. In general, pig farms obtained high scores for the KPIs feed conversion ratio, mortality rate and barn insulation, whereas lower scores were observed for sustainable water use. High variability was observed for most economic KPIs (e.g. family labor income and labor productivity) and for total energy use. Broiler farms generally scored high on liquidity, biosecurity and dead-on-arrival, while lower scores were observed for profitability and sustainable water use. Similar to pig farms, high variability was found for most economic KPIs (e.g. feed cost) and for renewable energy use. For the social dimension, both pig and broiler farmers generally scored well, with the highest scores achieved for management and access to advice and knowledge, whereas average scores were lower for networking and work-life balance. The results demonstrate the feasibility of a multidimensional, non-aggregated sustainability assessment approach and highlight the variability in performance both within and across sustainability pillars.

One Welfare : Perception and expectation by French representative of beef and dairy cattle sector

L. Mirabito[1], C. Coghetto[1], E. Delanoue[1]
[1] Idele, 149 Rue de Bercy, 75 012 Paris, France

Context and Objective. This study was part of the MICOW project which addresses the challenge of turning the "One Welfare" concept—linking animal welfare, farmers' well-being, and the environment—into a practical support method for French cattle farms. It starts from the observation that livestock farmers face growing, sometimes conflicting demands (productivity, regulations, societal expectations), and asks how a One Welfare–based approach could help in real farm conditions. The study's core questions focus on how diverse cattle-sector stakeholders understand One Welfare, what they expect from advisory/support methods, and how such a method could be operationalized in French beef and dairy systems. Methodology. The work followed a qualitative design conducted from March to August 2024. After an exploratory phase (literature review, context building, and exploratory interviews), we carried out 26 semi-structured interviews with a wide range of actors across French cattle value chains (e.g., advisory services, interprofessional bodies, technical and research organizations, veterinarians, and farmers). Interviews were recorded, transcribed, and analyzed through thematic content analysis (to identify recurrent ideas, tensions, and expectations) and typological analysis (to build stakeholder profiles based on their level of adherence to the One Welfare concept and willingness to implement it operationally). Results. Stakeholders broadly agreed that farmers' well-being and animal welfare are interconnected, but they differed in how they define animal welfare and how "One Welfare" should be interpreted. Many actors framed animal welfare using established references (e.g., "Five Freedoms" and ANSES' definition) while debating whether these sufficiently capture animals' emotional and individual dimensions. In contrast, farmers' well-being was harder for interviewees to define precisely, yet perceptions converged around physical and psychological comfort, workload, recognition, income, and the ability to rest. One Welfare was widely seen as promising but often "too conceptual," with many actors focusing mainly on the human–animal relation and leaving the environmental dimension less explicit. Operationalization proposals clustered around four formats: collective farmer groups, training advisors/technicians in a One Welfare approach, integrating One Welfare elements into existing diagnostic tools, and self-assessment tools for farmers. A typology identified four profiles—from highly supportive "enthusiasts" to skeptical actors who viewed implementation as too complex in terms of skills, time, and funding. Conclusion. We conclude that One Welfare has strong perceived relevance for supporting cattle farmers under current pressures, but its practical deployment requires clearer framing, shared tools, and coordinated multi-actor implementation. The study highlights the need for pragmatic, farm-adapted methods that avoid being perceived as accusatory, and for credible incentives and funding mechanisms. It also recommends further work that directly includes a broader, more diverse sample of farmers (beyond organizational representatives) and possibly explores other livestock sectors, while improving communication to align field interpretations of One Welfare with its more comprehensive academic definition.

One Welfare on a Family Beef Farm: Human–Animal Co-Agency Driving Environmental Adaptation and Relational Innovation

X. Boivin[1], M. Larue[2], P. Spoljar[3], E. Delanoue[4], B. Mounaix[6], C. Couzy[5], G. Barbier[1,7], R. Lardy[1], L. Mirabito[5]

Beef suckler systems depend on dynamic interactions between humans, animals, and environmental conditions, shaping welfare and agency. Within One Welfare, family farms offer a relevant context to analyse how farmers and cattle act as co-agents adapting to climatic constraints, managing landscape features, and resource availability. In such systems, the present study aimed to describe work organisation, innovation, and collective decision-making. It also aimed to identify adaptive practices triggered by environmental or behavioural cues. At last, it aimed to highlight risks and perspectives for improving safety, resilience, and sustainability. A qualitative case study was conducted on a family farm that transitioned from dairy to Limousine cattle 30 years ago. Semi-structured interviews and thematic analysis focused on routines, infrastructure, grazing management, and human–animal interactions. In this farm, work organisation is collective, anticipatory, and environmentally informed. Decisions on breed, grazing, or buildings are discussed within the family and supported by peer exchanges and training. Innovation is pragmatic: enrichment devices, ventilation changes, or building adjustments are tested before adoption. Farmers maintain a critical opinion toward costly solutions lacking clear justification, preserving human agency in decision-making, and economic viability. Environmental factors such as wind exposure, soil moisture, drought, humidity, water availability and shelter distribution play a central role in daily management. Farmers observe how animals select resting or grazing areas accordingly. These choices guide paddock rotation, building design, and circulation routes. Climate variability requires constant adaptation: windbreaks, adjusted wall protections, improved airflow and light, managed transitions between pasture and buildings, and maintenance of clean water points. Environmental mismatches can lead animals to leave inadequate pastures, coming "under farmers' windows" for signalling the need for rapid corrective action. Pasture quality and winter shelter strategies require yearly revision based on climatic trends and observed behaviour. Cattle are considered active partners influencing management through preferences, social dynamics, and behavioural signals. Farmers adapt by avoiding isolation of primiparous heifers, mixing age groups to support social learning, modifying water access when dominant animals block troughs, and providing simple enrichment to reduce fear and limit building damage. Calm handling, ritualised visits to calves, and culling of animals with poor temperament support human safety and animal emotional stability. This case study shows how One Welfare emerges through environmental and relational practices where humans and animals co-construct their shared environment. Innovation is grounded in routine decisions, and the family's critical evaluation of external advice reinforces autonomy and resilience. The system is continuously evolving, illustrating how family farms operationalise the One Welfare approach. This study was supported by the Carnot Micow Project.

How to balance three welfare dimensions in dairy farm management

A. Kuipers[1], E. Koloszyck[2], M. Klopcic[3]
[1] Wageningen University & Research, De Elst 1, 6708WD Wageningen, Netherlands, [2] West Pomeranian University of Technology, ul. K. Janickiego 31, 71-270 Szczecin, Poland, [3] University of Ljubljana, Groblje 3, 1230 Domzale, Slovenia

This study is based on the EU-project Resilience for Dairy, which dealt with challenges for the future facing the sector. The project aimed to develop a network on resilient dairy farms in the participating 15 countries during a 4-year period. On basis of statistical data, it is argued that size of farm (20-150 cows) has only a limited correlation with family income. Hitherto, management capacity is a dominant factor for farm viability. This presentation aims to examine how dairy farm management can balance three welfare dimensions – farmers' welbeing, animal welfare and environmental sustainabilitity – to support resilient long-term stategies. To support management, farmer needs and solutions, i.e. practices and techniques, were systematically gathered and assessed. Farmer needs were captured through European experts' meetings and in regional stakeholder workshops, resulting in a list of 43 categories of needs (rated on a scale from no contribution to great contribution to resilience) by using an online questionnaire. 535 stakeholders in the participating countries (70% farmers, 30% other stakeholders) scored the list of needs. Three key know-how fields emerged: the need for economic/ social resilience, technical efficiency, and adaptation to environmental and animal welfare standards. Next, 190 solutions – practices and techniques) – were chosen linked to these know-how fields on their expected contribution to farm resilience. An online survey assisted in assessing each solution separately; 3329 assessments were done with on average 53 solutions per expert assessor. Additionally, stakeholder workshops across Europe chose and ranked the 20 most urgent solutions in their country to strengthen farm resilience. Results indicated regional variation in needs across Europe (Western Europe vs Central and Eastern Europe) with differences related to technical efficiency, knowledge development, and environmental and animal welfare practices. Younger farmers tended to mention socio-economic aspects as income and work-life balance more often than older farmers. However, it was also noted that year-to-year issues which raise a lot of attention affected needs, like in Denmark by the introduction of a CO2-tax for dairy farms; in the Netherlands by the so-called N-crises, that shifted needs to more interest in soil health and quality; and in Slovenia by the assignment of NGO's to check on-farm for lack on animal welfare. From this study emerged the question how on farm level a trade-off between socio-economic welfare including communication with society (farmers' welfare), animal welfare, and environmental sustainability/welfare takes place to arrive at a resilient future farm business. Which factors affect a sound balance and strategy between these 3 x welfare components and is there a methodology available to support the management and manager in this context? This presentation will address these questions. As an example, an interactive strategic management program will be outlined in which the farm family develops its own plans in cooperation with experts and peer farmers, explicitly considering synergies and trade-offs between the three welfare dimensions. Keywords: 3 x welfare, farmers' welbeing, animal welfare, environmental sustainability, workshops, strategic management, future farm

Balancing three pillars of welfare to maintain a promising future for dairy farming in the USA

A. De Vries[1]
[1] University of Florida, Department of Animal Sciences, 2250 Shealy Drive, Gainesville, FL 32608, United States

To maintain a promising future, dairy farms in the USA need to meet the three pillars of welfare, be resilient and profitable. Human welfare relates mostly to human resource management in the USA. Dairy herd sizes have increased greatly in the last 20 years. The larger herd sizes of the remaining dairy farms have caused many farms to rely on hired outside labor. Many workers come from Latin America. As a rule of thumb, dairy farmers with more than 300 cows become human resource managers, rather than doing much of the physical work themselves anymore. Dairy farm labor management has been studied, practiced, and refined for over decades now. It receives constant attention at meetings for dairy farmers. Where two decades ago the topic of cow comfort received much attention, today there is at least equal attention on maintaining productive and happy workers willing to work hard for long hours. This varies from offering good pay, bonuses, housing, training, to safety regulations, respect and cultural awareness. Almost without exception, well-run and profitable dairy farms have excellent labor management. Because dairy farm workers are scarce, in part because the immigration policy is reducing the supply of foreign workers, there is much interest in improving labor efficiency and robotics to get more work done with fewer people. Thus, larger dairy farms in the USA have mastered human resources management in similar ways to midsize firms in other sectors that employ workers. Animal welfare is practiced primarily because it's seen as the right thing to do and makes business sense. There are animal welfare laws in the USA, but they're limited, fragmented, and mostly state-driven, especially compared to Europe. One example of a federal law is the humane slaughter act. Regarding conventional dairy farming, there are no laws about, for example, pasture access, housing or stocking density. Animal welfare is more addressed in private programs such as the National Dairy FARM (Farmers Assuring Responsible Management) Program. More than 98 percent of the milk supply now comes from farms participating in FARM Animal Care. It is common now to find cow stockmanship training and monitoring of the way cows are treated to ensure cow welfare. Modern dairy barns include free stalls with ample air, feed, water, and a clean, soft, well-sized place to lie down. Human and animal welfare are connected through an emphasis on comfort for both the worker and the cattle. However, special care of dairy animals is limited because of the business approach to dairy farming. Environmental stewardship is not labeled as "welfare" in the USA. Environmental stewardship is more regulated than animal welfare, for example through the federal Clean Water Act, manure handling rules, and, in some states, regulations about air emission. In addition, the public is demanding a commitment from the dairy sector to reduce dairy's carbon footprint, conserve water resources, promote water quality, and protect biodiversity. Examples of stewardship are the quantification of dairy's impact on the environment, and commitments to reduce it such as through research to obtain more environmentally friendly cows. In a broader sense, environmental stewardship also includes the communities of people where dairy farms are located. There is an awareness that dairy farms need to be community partners and be known for providing nutritious, healthy products. These three pillars of welfare are necessary but not sufficient for a promising future because dairy farms also need to remain profitable and able to absorb shocks to the dairy business.

Integrating Animal Welfare into Sustainability Assessment of Livestock Systems: A Scoping Review and Expert Consultation

D. Sun[1], L. Smith[1,2], M. Almeida[3], E. Merlot[4], M. Gagaoua[4], I. Rivelli[5], D. Yanez-Ruiz[5], S. De Ponti[6], R. Mcguire[7], D. Kenny[8], M. Vilain Rørvang[1]

Animal welfare is key to sustainable livestock production, yet its integration into sustainability assessment frameworks remains fragmented. This study aimed to i) map current knowledge on animal welfare integration, ii) identify welfare indicators and their operationalisation, iii) examine methodological challenges, and iv) elicit expert perspectives on optimal approaches. A scoping review (2015-2025) identified 26 studies integrating animal welfare into sustainability assessment across livestock species. Data extraction captured framework types, indicator categories, measurement scales, and welfare domain coverage of the indicators using the Five Domains Model. A focus group workshop with 15 animal welfare scientists, Life Cycle Assessment practitioners, and sustainability researchers addressed five research questions: i) indicator selection, ii) measurement challenges, iii) framework positioning, iv) trade-off handling, and v) future improvements. Seven framework types were identified, with multidimensional sustainability (27%) and conceptual frameworks (27%) most prevalent. In terms of approaches, management/resource-based proxies dominated (42%), while animal-based measures comprised only 27% despite being more direct welfare assessments. Welfare domain coverage of the indicators showed strong coverage of health (77%) and physical environment (69%) but limited mental state coverage (35%). Expert consultation revealed unanimous agreement that animal welfare is essential to sustainability, yet with divergent positioning views: integral component (47%), social pillar (18%), separate fourth pillar (24%), or cross-cutting (12%). Six major challenges emerged: data availability and scalability, functional unit(s) selection, lack of standardisation, measurement validity, context-dependency, and aggregation and weighing issues. Experts prioritised standardisation, databases, technological innovation, and framework integration. This study reveals substantial methodological diversity and limited consensus on animal welfare integration. Limited mental state coverage of the indicators shows that current frameworks predominantly assess physical welfare while neglecting affective experiences, which is the ultimate welfare determinant per the Five Domains Model. Unresolved questions regarding positioning, weighting, functional units, and valuation reflect philosophical tensions about animals' moral status. Progress requires: i) standardised indicators spanning all welfare domains including mental states, ii) comprehensive databases for routine assessment, iii) transparent value-based weighting engaging scientists and stakeholders, and iv) revision of international frameworks to explicitly accommodate animal welfare in livestock sustainability assessment.

Interrelationships between animal welfare and sustainability of on-farm best practices for poultry production

M. Perard[1], E. Caumette[2], G. Aubin-Houzelstein[3], A. Trocino[4], J. Nowak[5], J. Pawłowska[5], M. Ocepek[6], A. Jonassen[6], A. Collin[1], L. Elmersson[7]

Multiple practices are applied in broiler and laying hen production to improve animal welfare. Such practices may also have impacts on the environmental, social and economic sustainability dimensions, either positive (synergies), negative (trade-offs) or neutral. Within the action "Sustainability aspects of animal welfare-promoting livestock systems" of the European Partnership on Animal Health and Welfare (EUPAHW), a scoping review was conducted to map interrelationships and identify knowledge gaps between welfare improvement and other sustainability dimensions. This was applied on a selection of best practices improving animal welfare at the farm stage: "Outdoor access", "No use of cages", "Lower stocking density", "Lower growth genetics", "Microclimate management", "Good litter management", "Enrichments". Overall, there was an important imbalance in the number of articles found depending on the practice and dimension assessed. For economic sustainability, direct costs were often not displayed, and the dimension was envisioned through production parameters (egg laying rate, slaughter weight, feed conversion ratio, etc.). It was difficult to draw conclusions from best practices such as enrichments, where the economic impact varied greatly depending on the type of enrichment used. However, some practices clearly appeared to worsen economic sustainability, such as the use of non-cage systems, while other improved it, such as microclimate management. For environmental sustainability, quantitative assessments of environmental footprints were found for all practices but enrichments, though the indicators studied were not always the same (for instance, ammonia emissions were common while land use was less calculated). Apart from microclimate and good litter management, the environmental impacts were mostly negative. Regarding social sustainability, meat quality was the most studied, with impacts varying greatly depending on the conditions of the practices (e.g., strain). Consumers surveys were recurring, though results varied greatly across countries. The surveys usually addressed priorities when buying products, revealing contradictions between the willingness to improve animal welfare and to pay, and the act of purchase. Farmer surveys, especially on working conditions, were described in the literature for about half of the practices. Overall, this scoping review identifies knowledge gaps on the impacts of animal welfare best practices on sustainability dimensions. It also highlights the lack of tools and methods for complete and holistic sustainability assessments including animal welfare, allowing comparisons across studies and practices. This work was co-funded by the European Union's Horizon Europe Project 101136346 EUPAHW. Views and opinions expressed are those of the author(s) only and do not necessarily reflect those of the European Union or the European Research Executive Agency. Neither the European Union nor the granting authority can be held responsible for them.

Rational and Sustainable Rabbit Farming in Burkina Faso for Food Security and Income Creation for Vulnerable Populations: The SOAMBA project

L. Nompleggio[1], S. Giovannini[2], L. Bosa[1], A. Dal Bosco[1], S. Mattioli[1], C. Castellini[1]
[1] University of Perugia, Department of Agricultural, Food and Environmental Science, Borgo XX giugno 74, 06121 Perugia, Italy, [2] Tamat ETS, Via Dalmazio Birago 65, 06124 Perugia, Italy

Widespread hunger and poverty continue to characterize many Least Developed Countries in sub-Saharan Africa, reflecting a persistent failure in equitable food access and rural development. Addressing these challenges requires context-specific strategies grounded in local environmental and socio-economic realities. In West Africa, Burkina Faso faces climatic constraints, resource limitations, and structural vulnerabilities affecting agricultural productivity and food security. In response, the Italian Agency for Development Cooperation (AICS) has funded the SOAMBA project, contributing to SDG 2 (Zero Hunger) by strengthening the rabbit-meat value chain through integrated research–training–development framework. The project is led by the University of Perugia (Unipg) in partnership with Tamat ETS and five Burkinabé partners: The National School of Animal Husbandry and Health (ENESA), the Institute for Environment and Agricultural Research (INERA), the Association of Producers of Livestock Sectors in Burkina Faso (AFA BF), Association Manegdbzanga, and the Patronale Association of Hotels and Restaurants of the BF (APHRBF). The project is establishing two Genetic Centres at ENESA (Boulbi) and the Bangr Baoore Centre in Loumbila, designed as hubs for breeding improvement, research, and technical innovation. Current research activities focus on the characterization and enhancement of local rabbit genetic resources to increase productivity while safeguarding adaptive traits required under Sahelian climatic conditions. The objective is to raise average litter size from approximately five kits to 8–10, increasing annual production per doe. Within an agroecological framework, feeding formulations are being evaluated using local, non-competitive resources and agro-industrial by-products, including mango processing residues, moringa, amaranth, and sweet potato leaves. Circular production principles are reinforced through agroecological practices, including organic mounds fertilized with rabbit manure. Additionally, heat-resistant housing and static refrigeration systems are being prototyped to safeguard animal welfare and meat quality. The sustainability of the initiative relies on a Training-of-Trainers model. Capacity-building courses are being developed on site and in Italy. By embedding knowledge transfer within Burkinabé institutions, the initiative promotes self-sustaining capacity development beyond its timeframe. Training outcomes are evaluated through standardized tools. Selected technicians undertake a residency at Unipg to act as local trainers and innovation catalysts. In parallel, satellite family farms are being developed in Loumbila and Saaba. This model facilitates the scaling-out of rabbit production among rural households as a food security strategy. Beneficiary selection ensures at least 45% female participation and facilitates the inclusion of persons with disabilities. By integrating animal genetics, sustainable housing and feeding, technical capacity, and circular models, SOAMBA operationalizes the One Welfare framework, proposing resilient and locally adaptable pathways to improve food security and livelihoods.

Farmers' Negative Emotions as a Component of the Administrative Burden of Farm Supervision

T. Simonen-Jokinen[1]
[1] *University of Vaasa, School of Management, Wolffintie 32, 65200 Vaasa, Finland*

Background Administrative burden refers to additional work farmers must carry out for purposes other than their own operations. Such tasks include notification and reporting obligations, permit procedures and support applications. Psychological stress, which includes fear and other negative emotions, is part of administrative burden. Administrative burden may accumulate when a farm faces simultaneous obligations from both the industry and public authorities. Emotions can also be influenced by so-called annoyance effects, which refer to the combination of the comprehensibility of the legal requirements, the ease of implementing the statutory information obligations, and the acceptability of the obligations. Farmers' well-being can be a limiting factor for providing good care for animals; thus, identifying ways to reduce the administrative burden linked to animal welfare supervision and farm subsidies is important. Objectives The aim of this study was to identify risks that may compromise farmers' legal protection and to explore the administrative burdens associated with animal welfare supervision and animal-related subsidies. Methods The research data were collected through thematic interviews of twelve voluntary Finnish cattle and sheep farmers. Before the interview, interviewees received an information brochure and privacy statement, and consent was obtained. The themes covered topics such as subsidies affecting animal welfare, sources of regulatory information, supervision procedures, role of the industry, and farmers' development proposals. Anonymised summaries were analysed using Atlas.ti software using inductive approach. Results The interviews revealed a wide range of negative emotions including stress, fear, a sense of injustice, tension, strain, uncertainty and external pressure. The most frequent risk to legal protection was inconsistent interpretation of regulatory conditions. Uncertainty of interpretations underlied stress and other negative emotions. Factors that can reduce psychological strain included familiarity with the supervisor, farmer involvement in policy design, education, clear legal rules, and considering the long-term perspective of agricultural work. Discussion & conclusion Administrative burdens drain farmers' resources and may risk both farmer and animal welfare. Inconsistency among supervisors' interpretations both undermines legal protection and increases administrative burden. Ethical, trust-building supervision requires that all farmers are treated according to the same rules and guidelines. Farmers need sufficient information to comply with regulations, and providing this information is the responsibility of authorities. While clear instructions help farmers understand their legal position, excessive guidance may lead to information overload, hindering the intended clarity. Broader consultation with farmers would help strengthen animal welfare policies by identifying actions that engage farmers and help reveal potential issues that may give rise to disagreements. Clear communication, customer encounters and interaction play a key role in experience of regulatory burden. The agricultural support system is characterised by constant change: some rules evolve quickly, while others change only slowly. The slowness of change is also partly due to path dependency, and institutionalisation, which means that the solutions made have many advantages, which makes them difficult to dismantle. Steadiness of regulations also support legal certainty. Stress and the risk for burnout can also threaten animal welfare on farms. Sustainable farming must therefore encompass farmer well-being. Psychological burden should also be considered when evaluating administrative burden.

Animal welfare and sustainability of pasture-based dairy production: a Life Cycle Assessment modelling approach

M. Dos Santos Lima[1], L. Torricella[1], L. Annetti[1], G. Vignola[2], A. Collin,[3], M. Podaliri Vulpiani[1]
[1] nstitute Zooprofilattico Sperimentale dell'Abruzzo e del Molise G. Caporale,, Department of Animal Welfare and Animal Husbandry and Research - WOAH Collaborating Centre for Animal Welfare, Via Campo Boario,, 64100 Teramo, Italy, [2] University of Teramo, Department of Veterinary Medicine - Animal Welfare, Production Sustainability, and Technological Innovation in Livestock Farming, Nepezzano, Piano D'accio, 64100 Teramo, Italy, [3] INRAE - Université de Tours, BOA (Biologie des Oiseaux et Aviculture - Bird Biology and Aviculture), Val de Loire, 07 Nouzilly, France

The sustainability of livestock production is a strategic priority for European agriculture. Within this framework, animal welfare (AW) is increasingly recognised as a key determinant of both environmental and economic sustainability of farming systems. In the context of the European Partnership on Animal Health and Welfare (EUPAHW), this study develops a Life Cycle Assessment (LCA) modelling approach to evaluate the impact of welfare conditions in pasture-based dairy cows on the carbon footprint of milk production. A targeted literature review was conducted focusing on semi-intensive grazing systems with rotational pasture management. Several welfare impairment conditions were considered, including lameness and hoof disorders, inadequate nutrition and water access, heat stress and lack of shade, parasitic and infectious diseases, injuries, and social competition. For each factor, the effects on productive performance and environmental sustainability were assessed. The carbon footprint was calculated per kg of fat- and protein-corrected milk (FPCM), comparing an optimal welfare scenario (baseline) with different impaired welfare scenarios, considering both single factors and combined conditions. The increase in emission intensity (kg CO_2-eq/kg FPCM) was estimated through the integration of bibliographic data and modelling tools. Preliminary results indicate that compromised welfare conditions at pasture lead to an increase in milk emission intensity compared with the optimal the analysis also highlighted significant knowledge gaps in available datasets, suggesting the need for targeted experimental studies. Overall, the study demonstrates that improving animal welfare can represent an effective climate mitigation strategy in pasture-based dairy systems, aligning environmental and productive objectives. This work was co-funded by the European Union's Horizon Europe Project 101136346 EUPAHW. Views and opinions expressed are those of the author(s) only and do not necessarily reflect those of the European Union or the European Research Executive Agency. Neither the European Union nor the granting authority can be held responsible for them

From preventing suffering to measuring positive welfare: Can biological markers reflect Animals' lifetime experiences?

L. Morgan[1,2]
[1] Shmunis School of Biomedicine and Cancer Research, Tel Aviv University, 6997801 Tel Aviv, Israel, [2] PigO FoodTech, 71 Hagefen, 7079500 Qidron, Israel

Animal welfare science has traditionally focused on identifying and preventing suffering. However, increasing attention is now being given to positive welfare and to understanding whether animals experience a life worth living. Addressing this challenge requires indicators that reflect not only momentary states but also the cumulative balance of positive and negative experiences across an animal's lifetime. Research, not necessarily conducted in non-human or farm animals, suggests that several biological analyses may provide promising indicators of cumulative experiences. These include, for example, changes in brain plasticity, telomere dynamics, oxidative stress pathways, immune function, the gut microbiome, and metabolomic profiles. While many of these approaches have primarily been studied in relation to negative exposures, emerging work indicates that they may also capture aspects of positive experiences and long-term welfare states. In this talk, current research and conceptual developments on biological indicators of positive and cumulative welfare will be reviewed, highlighting metabolomics as an emerging tool for understanding how lifetime experiences become biologically embedded. Although none of these measures currently provides a definitive indicator of positive welfare, they offer promising methodological directions for advancing welfare assessment, particularly when used in combination.

Wool Cortisol Reveals Cumulative Welfare and Physiological Resilience in Sheep Production Systems

S. Ocak Yetişgin[1], U. Sen[2], H. Onder[1]
[1] Ondokuz Mayıs University, Department of Animal Science, Kurupelit Kampüsü, 55139 Samsun, Turkey, [2] Ondokuz Mayıs University, Department of Agricultural Biotechnology, Kurupelit Kampüsü, 55139 Samsun, Turkey

Chronic stress represents a cumulative welfare burden in extensive sheep systems, yet robust longitudinal indicators remain limited. This study evaluates wool cortisol as a retrospective biomarker of long-term welfare across contrasting production environments. Karayaka sheep (n = 75) were monitored over 8 months with repeated wool sampling (8 time points) under intensive housing, short-distance transhumant pastoralism, and long-distance highland pastoralism. All animals were exposed to comparable environmental and management-related stressors within their respective production systems, without the application of differential experimental treatments across subgroups. Wool samples were consistently collected from regrown fleece, reflecting cortisol accumulation over the preceding growth period. Wool cortisol concentrations ranged from 3.22 to 7.00 pg/mg, showing significant production system × season interactions ($P < 0.05$). Short-distance pastoral flocks exhibited the highest mean cortisol (5.49 ± 0.20 pg/mg), with pronounced elevations during winter confinement, indicating welfare challenges associated with abrupt environmental transitions. Long-distance migrating sheep showed transient post-migration stress peaks followed by marked physiological recovery during alpine grazing (July: 3.33 ± 0.20 pg/mg), suggesting adaptive resilience under continuous extensive management. Intensively housed sheep displayed lower overall cortisol (4.85 ± 0.20 pg/mg), yet summer heat stress revealed concealed welfare costs of confinement. Lambs showed lower cortisol levels than adult ewes; however, these differences were not statistically significant ($P > 0.05$). These findings support wool cortisol as a sensitive longitudinal welfare indicator integrating climatic exposure, housing conditions, and mobility-related stress. Beyond detecting acute responses, this biomarker captures cumulative physiological load and recovery dynamics, offering practical value for welfare-oriented management. Wool cortisol provides a scalable tool for monitoring welfare trajectories and identifying critical intervention periods, particularly during seasonal transitions in pastoral systems

Telomere Length as a Genomic Biomarker of Environmental Stress in Dairy Goats

F. Sarubbi[1], R. Tudisco[2], A. Gallo[3], A. Siciliano[3], G. Cappelli[3], J. L. D'Auria[3], R. Pistucci[1], F. Infascelli[2], P. Iommelli[4], A. Iannuzzi[1]

The identification of sensitive molecular indicators capable of capturing physiological responses to environmental stressors is a priority in livestock farming. In this context, molecular biomarkers can support precision livestock farming approaches by complementing sensor-based data with biologically meaningful information. Among these, telomere length (TL), a marker of cellular aging and oxidative stress, is emerging as a promising genomic biomarker in domestic species, being relatively rapid and cost-effective to measure under standardized conditions. Longer telomeres are generally associated with better health status and improved welfare. Moreover, TL dynamics are generally coordinated across tissues and reflect systemic physiological conditions, supporting their assessment in minimally invasive matrices such as milk. This study evaluated TL dynamics in dairy goats exposed to acute environmental stress under field conditions. Twenty grazing goats were monitored across three sampling points. A period characterized by high humidity and severe storm events was associated with a significant increase in serum cortisol concentrations ($P < 0.01$), accompanied by a significant decrease in milk-derived TL (expressed as T/S ratio; $P < 0.05$). Following the return to stable environmental conditions, both cortisol levels and TL values showed recovery trends. Correlation analysis revealed significant negative associations between TL and humidity ($r = –0.62$; $P < 0.01$) as well as dew point ($r = –0.58$; $P < 0.05$), supporting the sensitivity of TL to climatic stressors. These findings indicate that acute environmental challenges can induce measurable telomere shortening, reflecting increased cellular strain. Overall, TL responded consistently to short-term physiological stress and aligned with endocrine changes, supporting its role as an integrative biomarker of animal welfare. The integration of TL into field-based assessments may provide a valuable tool to detect early biological responses to environmental challenges, contributing to more informed and adaptive management strategies in small ruminant production systems.

Mapping Sleep Architecture in Nellore Beef Cattle: Validation of a Custom Polysomnography System

D. H. M. Watanabe[1], F. F. Alves[1], P. H. F. Torres[1], M. Lhamon[2], K. Donohue[2], B. O'Hara[3], D. D. Millen[1]
[1] Faculty of Agricultural and Veterinary Sciences, São Paulo State University, Jaboticabal campus, Department of Animal Science, Via de Acesso Professor Paulo Donato Castelane Castellane S/N - Vila Industrial, 14884-900 Jaboticabal, SP, Brazil, [2] Signal Solutions, LLC, 145 Graham Ave Lexington, 40506 Lexington, KY, United States, [3] College of Arts and Sciences, University of Kentucky, Department of Biology, 101 T.H. Morgan Building, 195 Huguelet Dr., 40508-0225 Lexington, KY, United States

Sleep is essential for mammals, and deprivation can impair immune function, increase energy expenditure, and heighten pain sensitivity (Bergmann et al., 1989; Moldofsky, 2001; Bonnet, 2005). Despite its importance, sleep in beef cattle remains poorly characterized. Most available data derive from lactating dairy cows, in which the physiological demands of lactation may influence sleep patterns. Therefore, this study aimed to validate a custom-made polysomnography (PSG) system to characterize sleep stages in Nellore beef cattle through electroencephalography (EEG), electromyography (EMG), and heart rate monitoring. Two Nellore steers (645 kg body weight) were fitted with a seven-channel PSG unit and monitored for 12 h (18:00 to 06:00). Four EEG electrodes were positioned on the frontal region to record cortical activity, while three additional channels recorded heart rate (bilaterally below the rib cage) and muscle tone via EMG (neck region). Animals were housed in 6.0 × 3.0 m pens without artificial lighting and fed a diet of corn silage and mineral supplements. During the recording period, two trained observers continuously monitored behavioral activity (idle, eating, ruminating), posture (standing, lying, tucked), and eye status (open or closed). Data were analyzed in 30-s epochs. Sleep stages were classified based on EEG, EMG, and heart rate patterns. Wakefulness was characterized by desynchronized, low-amplitude, high-frequency EEG activity (14–30 Hz), high muscle tone, and variable heart rate. Drowsing showed mixed synchronized/desynchronized EEG patterns with low-to-moderate amplitude and frequencies between 4 and 12 Hz, moderate muscle tone with maintained posture, and slightly reduced heart rate. Non-rapid eye movement (NREM) sleep was defined by synchronized slow-wave activity with high amplitude and low frequency (10–15 Hz), reduced muscle tone, and lower heart rate. Rapid eye movement (REM) sleep presented desynchronized, low-amplitude EEG activity (4–8 Hz), near-complete muscle atonia, and a less regular heart rate. Behavioral observations supported PSG classification, particularly to account for EEG artifacts caused by rumination. During the 12-h period, cattle spent 505 ± 26.87 min awake, 165.25 ± 68.24 min in drowsing, 25.25 ± 10.25 min in NREM sleep, and 24.5 ± 31.11 min in REM sleep. Within total sleep time, drowsing predominated (76.9%), followed by NREM (11.7%) and REM (11.4%). Inter-animal variability was greater than expected, suggesting that reactivity to the mounted PSG equipment may have influenced sleep expression. Compared with lactating dairy cows reported by Kull et al. (2019), which spent 87.37% of sleep time in drowsing, 11.58% in NREM, and 1.05% in REM, Nellore steers exhibited a proportionally greater REM duration, indicating possible physiological or production-system differences in sleep architecture. However, further investigation is required, as sleep data in dairy cows were collected over a 24-hour recording period. In conclusion, the custom-made PSG system reliably characterized brain activity and sleep stages in Nellore beef cattle. These findings establish a methodological foundation for investigating sleep quality as an innovative and objective indicator of welfare in beef production systems.

Social touch as a positive welfare phenotype in livestock: a cross-disciplinary synthesis of sensory and behavioral evidence

C. Winters[1]
[1] ETH Zurich, Universitätstrasse 2, 8092 Zurich, Switzerland

Social touch is the most direct form of social contact, yet it remains comparatively understudied in behavioral and sensory research. Work in humans and rodents has focused on a specialized class of unmyelinated afferents, C-low threshold mechanoreceptors, as key mediators of affective touch. These skin fibers terminate as longitudinal lanceolate endings around hair follicles and are optimally tuned to slow, stroking at skin temperature. Their activation encodes hedonic aspects of tactile input and contributes to stress regulation and reward processing. Although C-low threshold mechanoreceptors have been identified, their peripheral organization has rarely been examined in relation to naturally occurring tactile behavior. By synthesizing findings from sensory neuroscience, behavioral biology, and animal welfare research, this review integrates mechanistic knowledge of peripheral tactile systems with empirical observations of social behavior in farmed animals. It highlights how stimulation of C-low threshold mechanoreceptors engages neural circuits linked to reward and stress regulation, and how these interactions can be conceptualized as measurable phenotypes. The review frames social touch as a biologically grounded phenotype, linking the tactile architecture to ethological observations and potential practical applications for livestock species. Neuroanatomical studies in rodents show that C-low threshold mechanoreceptors are distributed non uniformly across the body surface, with higher densities in regions such as shoulders and back. Behavioral observations indicate that these areas are preferentially targeted during affiliative interactions, suggesting a functional relationship between receptor topology and social touch. Comparable patterns have been reported in other mammals, and stimulation of receptor rich regions directly engages neural circuits involved in reward and stress regulation. Together, these findings indicate that tactile input from different body areas carries distinct biological significance. Methodological advances, including computer vision, allow quantification of spatiotemporal patterns of contact in group housed animals. Integrating these tools with knowledge about peripheral sensory organization could provide objective, low bias indicators of positive welfare which are urgently needed in livestock production. While the study of positive animal welfare has advanced, robust empirical indicators remain limited. Many current measures rely on context-dependent behaviors or subjective interpretations and have yet to be linked to mechanistic processes constraining reproducibility across species and systems. Social touch offers a promising avenue for addressing this gap. In livestock, interactions are often described broadly without detailed sensory analysis. Integrating social touch with sensory neurobiology provides a mechanistic scaffold, allowing spatiotemporal patterns of contact to be conceptually framed as a biologically grounded candidate phenotype of positive welfare, offering a testable approach for future research. Based on cross-disciplinary evidence, this review argues that social touch offers an interesting avenue in the search for biologically grounded and ethically relevant phenotype in livestock species. Situating tactile experience within the framework of positive welfare highlights its potential role in shaping stress regulation, social stability, and developmental trajectories. This approach contributes to a more comprehensive understanding of animal wellbeing, supports evidence-based refinement of management practices, and aligns livestock research with broader societal expectations regarding the promotion of positive states in farmed animals.

Benefits of temporary access to enriched environments for finisher pigs

M. Cupido[1,2], L. Boyle[1], S. Mullan[2], K. O'Driscoll[1]
[1] Teagasc, Pig and Poultry Development Department, Moorepark, Shanacloon, Fermoy, P61 C996 Cork, Ireland, [2] University College Dublin, School of Veterinary Medicine, Belfield, Dublin 4, D04 V1W8 Dublin, Ireland

In recent years, in addition to minimising negative experiences, there is growing appreciation of the importance of positive experiences when it comes to ensuring good animal welfare standards. Pigs in conventional systems are often kept in pens offering limited opportunity to express natural behaviours. Economic limitations restrict pig producers' capability to modify these pens to provide outlets for rooting and exploratory behaviour. However, temporary access to an enriched pen could help to satisfy the intrinsic behavioural needs of pigs, without requiring structural modifications to the home pen. In this 2×2 factorial study, half of the pens across two housing systems – the "Conventional" vs "Alternative" (n=18 pens respectively) – were given access to an enriched pen (EA) for one hour, twice a week, for eight consecutive weeks during the finisher period. The remaining pens had no access (NA). Conventional pens were indoors and fully slatted (0.90m2/pig). Alternative pens had a higher space allowance (1.13m2/pig), 79% solid flooring, an internal resting area, and a covered 'outdoor' area where one wall was open to the outdoors. All home pens were equipped with a rack containing straw. Prior to each enrichment access session (EAS), EA pigs were played an audio cue for two minutes. Displays of anticipation (pushing the gate or other pigs to access the gate, head tosses, play) was observed continuously before the final EAS (Week 8, session 2) for all pens. Behaviour was observed throughout an entire EAS during the 3rd, and the final (8th) week of access, via six one-minute continuous observation sessions every ten minutes (6 minutes in total per pen). All counts of play-like behaviours (pivots, head tosses, flops, play fighting) were recorded. Tail (0 = no lesion, 1 = bite marks, 2 = open wound, 3 = infected wound), ear (0 = no lesion, 1 = superficial punctures, 2 = brown/red scab, 3 = bloody lesion on intact ear, 4 = bloody lesion on ear with missing tissue), and body lesions (0 = no lesion, 1 = brown scab, 2 = single red scratch, 3 = >1 red scratches, 4 = single lesion with broken skin, 5 = >1 lesion with broken skin) were scored on focal pigs (Conventional: n=4/pen; Alternative: n=10/pen) every second week. Data were analysed using SAS v9.4. Pigs in EA pens performed more anticipatory behaviours when presented with the audio cue ($P<0.05$) than pigs in NA pens when played the same audio cue. EA pigs performed more pivots and head tosses ($P<0.05$) during the beginning of the EAS. Thereafter the performance of these behaviours decreased and plateaued. Lesion scores did not differ between treatments. No differences were observed between housing systems for any of the measures taken. The performance of anticipation behaviours by EA pigs indicates that they considered EAS as a positive experience. The performance and plateauing of positive behaviours during EAS support this and signifies that one hour was sufficient for a complete behavioural outlet. Similarities in lesions across treatments demonstrates that returning to the home pens did not cause frustration in the pigs. This enrichment strategy is unlikely practical, but it helped us to understand pigs need for positive experiences in commercial production environments.

Damaging and play behaviours linked to brain neurochemicals in pigs

G. Troupakis[1], I. Minussi[1,2,3], W. J. J. Gerrits[2], A. J. M. Jansman[3], M. Diepeveen-De Bruin[4], Y. Vermeiren[4], J. E. Bolhuis[1]

[1] Wageningen University, Adaptation Physiology Group, De Elst 1, PO Box 338, 6700 AH Wageningen, Netherlands, [2] Wageningen University, Animal Nutrition Group, De Elst 1, PO Box 338, 6700 AH Wageningen, Netherlands, [3] Wageningen Livestock Research, Animal Health & Welfare, De Elst 1, PO Box 338, 6700 AH Wageningen, Netherlands, [4] Wageningen University, Nutritional Biology Group, Stippeneng 4, PO Box 17, 6700 AA Wageningen, Netherlands

Immune activation and stress can alter several metabolic pathways, thus affecting animal behaviour and emotional (affective) states. The aim of this study was to explore the relationships between positive and negative behaviours of pigs that may reflect their affective states and several brain analytes, using data from a previous experiment. From weaning (at 4 weeks) onwards, 46 female, pair-housed pigs were kept under high (HSC) or low (LSC) sanitary conditions and were offered either a diet deficient in the first 8 essential amino acids (NFC) or a choice between the deficient diet and a diet enriched with the same 8 amino acids (FC). Treatments HSC-FC and LSC-FC had 8 pens, whereas HSC-NFC and LSC-NFC had 4 pens. Durations and frequencies of damaging behaviour (biting pen mates' ears, tail, or other body parts), aggression, and play were recorded continuously on day 16 from 07:00 to 19:00h. On day 18, pigs were euthanised to obtain samples from the hippocampus and prefrontal cortex for analysis of concentrations of compounds involved in the kynurenic and serotonin (5-HT) pathways, and the catecholaminergic system. After transformation, residuals of the variables were extracted from a general linear model to remove treatment effects and allow examination across treatments. For each brain region, a principal component (PC) analysis was run to reduce the number of variables (neurochemical residuals). Pearson correlation coefficients (r) were calculated to assess the relationships between behavioural residuals and retained PCs; individual neurochemical residuals that did not load on any PC; and residuals of neurochemical ratios. To control for multiple comparisons, Storey's q-value procedure ($q < 0.10$) was applied. As results were similar for behavioural durations and frequencies, only the latter are reported. In the hippocampus, play fight ($r = 0.43$, $q = 0.02$) and total play ($r = 0.28$, $q = 0.06$) correlated positively with a PC with high loadings of 5-HT, dopamine, their respective metabolites 5-hydroxyindoleacetic acid and homovanillic acid, and norepinephrine (NE); and negatively (play fight: $r = -0.47$, $q = 0.01$; total play: $r = -0.33$, $q = 0.07$) with a PC with high loadings of tryptophan (TRP), kynurenine (KYN), and epinephrine (EPI). In the same brain region, play fight ($r = 0.62$, $q < 0.001$) and total play ($r = 0.32$, $q = 0.08$) correlated positively with the 5-HT/TRP ratio and negatively (play fight: $r = -0.61$, $q = 0.002$; total play: $r = -0.50$, $q = 0.007$) with the EPI/NE ratio. Hippocampal kynurenic acid (KA) correlated positively ($r = 0.42$, $q = 0.007$) with total play and negatively ($r = -0.27$, $q = 0.06$) with damaging behaviour. Similarly, the KA/KYN ratio correlated negatively with damaging behaviour ($r = -0.35$, $q = 0.05$) and positively with total play ($r = 0.42$, $q = 0.04$) in the hippocampus, and with total play in the prefrontal cortex ($r = 0.47$, $q = 0.03$). Lastly, damaging behaviour correlated positively ($r = 0.42$, $q = 0.06$) with the 5-HT/TRP ratio in the prefrontal cortex. In conclusion, our results point to a beneficial link between pig behaviour and KA, which has neuroprotective properties, and a negative link with the inflammatory pathway. The exploratory nature of the study precludes causal inferences, but these findings can form the basis for future research aimed at improving pig welfare and health.

Group and individual patterns in calf activity during a play arena test

J. D. Bus[1], M. A. Mason[1], M. B. Jensen[1]
[1] Aarhus University, Department of Animal and Veterinary Science, Blichers Alle 20, 8830 Tjele, Denmark

Calves' motivation to perform locomotor play, a putative indicator of positive welfare, can be assessed by releasing them into a large arena. Understanding how calves behave during such arena tests is essential to methodological design and correct data interpretation. While large individual variation in locomotor play has been mentioned by previous studies, baseline behavioural patterns at group and individual level during arena tests have scarcely been reported. This pilot study quantified and visualised group- and calf-level activity during a 20-min individual arena test (6 x 8 m, 30 cm-deep sand flooring) on two consecutive days. Calves (n = 12, 6-7 weeks old, individually housed) were fitted with a tri-axial accelerometer (HOBO pendant G data logger, Onset Computer Corp) on the left hind leg, which sampled at 4 Hz. For every 5 s of the arena test, the proportion of calves with at least one acceleration value < -2 or > 1.2 g was calculated, indicating high locomotor activity (hereafter referred to as 'playing'). At group level, calves played throughout the test, with activity being highest during the early stages. On d1, ~40 % of calves played immediately upon test start, with this peaking at ~60% around 4 min and then gradually declining to ~20% after 13 min. On d2, ~60% of calves played immediately upon test start, with this gradually declining to ~20% of calves after 7 min. At calf level, individuals played during (mean ± SD) 36.1 ± 10% of 5-s periods on d1 and 24.4 ± 6.3% on d2, ranging from 12.9% to 47.9 % on d1 and 10.8% to 31.2 % on d2. Visually, the temporal patterns varied, with some calves playing immediately after entering the arena but stopping quickly, some playing throughout, and some playing mainly mid-test. For example, on d1 the least and most active calves played during 6.7% vs. 75.0% of 5 s-periods in the first 5 min and during 3.3% vs. 48.3% of periods in the last 5 min. These results suggest that locomotor play was generally highest at the start of exposure, particularly on a second day, but could persist for up to at least 20 min. Calves differed in both the amount and timing of play. These findings can help determine appropriate play arena test durations depending on the research aim, and demonstrate that large individual variation should be taken into account regardless of test design. This work was co-funded by the European Union's Horizon Europe Project 101136346 European Partnership on Animal Health and Welfare as part of an internal project (SOA13).

Herd lying concordance: a novel measure of resting coherence in dairy cows

G. Franchi[1], D. W. Olijhoek[1], L. K. Hilligsøe[1], N. P. Hansen[1], E. M. V. Hvas[1], E. H. Jensen[1], M. Larsen[1], L. J. Pedersen[1], M. B. Jensen[1]

[1] Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark

Behavioural synchrony in social animals is considered a welfare-relevant indicator of social cohesion. In dairy cattle, lying behaviour constitutes a major portion of daily activity budgets, with long lying bouts (typically 60–99 min indoors) expected under favourable conditions. Conventional metrics classify intervals as synchronous when an arbitrary proportion of the herd is lying within an interval (e.g., >70%). Although practical, this dichotomous approach does not reflect the graded nature of collective resting. We introduce and evaluate a suite of continuous Herd Lying Concordance (HLC) metrics that quantify synchrony as the degree of alignment in individual lying time within a group. Using 15-min summaries of individual lying time, synchrony is expressed as a dispersion-based concordance index, where lower variation among cows indicates stronger behavioural alignment. This formulation captures partial overlap, avoids threshold dependence, and reflects the expectation that biologically meaningful resting occurs as sustained and coherent group-level patterns. Forty-two healthy, lactating Danish Holstein cows were equipped with leg-attached accelerometers (IDS i-QUBE, Peacock Technologies, UK) and allocated to 3 treatments (indoor loose housing, N=14; continuous grazing (CG), N=13; rotational grazing (RG), N=15) in which they remained for 12 weeks under spring–summer conditions. For each 15-min interval, we computed four dispersion-based HLC metrics: standard deviation (SD), mean absolute deviation (MAD), interquartile range (IQR), and Shannon entropy of the lying time distribution. The coefficient of variation was excluded from formal modelling due to lack of boundedness. Each computed HLC metric ranged from 0 (no synchrony) to 1 (almost perfect synchrony). We evaluated HLC metrics using GLMMs, including treatment, week, and their interaction as fixed effects, z-standardised weather covariates (relative humidity, temperature, precipitation), and a random intercept for treatment group. The HLC metrics were evaluated based on model fit (AIC), treatment effect detectability (i.e., signal-to-noise ratio defined as mean absolute treatment contrast divided by its standard error), temporal stability (mean SD of weekly values across treatments), and robustness to outliers (ratio of the SD to the MAD). A robust HLC metric combines lower AIC, higher signal-to-noise ratio, higher temporal stability, and lower outlier sensitivity. Validation also addressed construct validity against 70% threshold synchrony (sync70) and discriminant validity against daily lying time and lying bout duration. The MAD-based formulation showed the best model fit (−1365.2), highest temporal stability (0.015), signal-to-noise ratio of 13.7, and high outlier robustness (1.108). Construct validity was confirmed via Wilcoxon rank-sum test (P<0.001) and logistic regression. Discriminant validity was supported by a negative correlation with lying time (rs=−0.55; P<0.001) and a positive correlation with mean lying bout duration (rs=0.52; P<0.001), confirming HLC-MAD captures resting coherence independently of duration. Night-window stability (22:00-04:00) was 3–6× greater than sync70. Incremental validity was confirmed by model comparison (ΔAIC=66.2 over sync70 alone). Both grazing treatments showed higher HLC-MAD than indoor housing (CG=0.964 and RG=0.966 vs. Indoor=0.924; P<0.001) and did not differ from each other (P>0.1), suggesting the benefit is attributable to pasture access per se. HLC-MAD provides a biologically grounded, threshold-free indicator of collective resting synchrony in dairy cattle.

Effect of a two-hour daily exit on milk quality, activities and outside behavior of Italian Simmental lactating cows

S. Arango[1], L. Bailoni[1], N. Guzzo[1], S. Currò[1], E. Bianco[3], E. Simonetti[3], S. Rainis[3], C. Sartori[2]
[1] UNIPD, BCA, Viale dell'Universitá 16, 35020 Padova, Italy, [2] UNIPD, DAFNAE, Viale dell'Universitá 16, 35020 Padova, Italy, [3] ERSA, Via Sabbatini 5, 33050 Udine, Italy

Mixed management systems combine indoor confinement plus an outdoor time for cows to pasture or to use as an exercise area. They had arisen as a new trend in dairy cows' management mostly due to welfare concerns from consumers. But, raising cows in a free stall with an automatic milking system while offering a daily exit in a paddock may be challenging for farmers. This study investigated the effect of a two-hour daily exit on milk traits, activities and outside behavior of dairy cows. A four-week trial was conducted using 10 lactating cows divided into two homogeneous groups (IN and OUT) for DIM (129.2 ± 18.8), parity (3.0 ± 1.4) and absence of mastitis and lameness. The experimental design was a crossover (2 groups x 2 periods), so each group was alternatively IN or OUT in each period. Both groups were reared in a free-stall, but meanwhile the IN group remained always inside, the OUT group had a two-hour daily exit (15:00-17:00) to a paddock. Milk yield, milk quality, and activities were monitored via individual collars linked to the automatic milking machine (AMS). Activities included the number of milkings, feeding (min/d), feed intake (kg/d), and rumination (min/d, min/h). Outdoor behaviors were monitored using six digital video cameras covering the paddock area (1500 m2) and connected to a digital video recorder. Recordings were analyzed by a trained observer. Climate data (relative humidity, temperature, wind speed, solar radiation, and rainfall) and the adjusted Temperature-Humidity Index were used to better understand outside behaviors. Statistical analysis followed a mixed model. Results showed a higher daily number of milkings for the IN group (3.02 vs. 2.88; $P<0.05$), but no differences in milk production (on average 32.6 kg/d) or milk quality traits such as: fat, lactose, and SCS. Milk protein was higher for the IN group (4.81 vs. 4.80 %; $P<0.05$). Eating behavior parameters were not affected by the treatment with a daily average of 236 minutes of feeding and 4.53 kg of compound feed intake. Daily rumination was higher for the IN group (485 vs. 472 min), primarily due to the lower rumination of the OUT group during the exit (at 16:00) (19 vs. 7 min). The main outdoor behaviors were standing (60.45%), grazing (38.10%) and ruminating (11.81%). Rainfall affected ($P<0.05$) walking, standing, positive interaction, playing and sexual behavior. In conclusion, offering lactating dairy cows a two-hour daily exit in the afternoon appears to be an effective mixed management system, allowing cows to exhibit natural behavior while maintaining milk production and composition comparable to a full indoor system. This system could be viable for Italian farmers to add value to the final product but the provision of some shade inside the paddock should be considered in order to avoid discomfort in cows. Positive animal welfare (PAW) goes beyond the current focus on minimizing negative states (such as pain, fear, injury, and disease) by emphasizing the inclusion of positive experiences and emotional states in animals. This study was part of the COST Action LIFT (CA21124), and aimed to systematically identify and characterize technologies that have potential to be used on commercial farms to monitor aspects of PAW in livestock. A scoping review was conducted in July 2024 using PubMed, Scopus and Web of Science. Eligible studies were original research written in English and published between 2014 and 2024. Five technology-specific search queries were used, targeting automated behaviour monitoring, wearable sensors, sound-based technologies, imaging, and integrated data-driven systems. After duplicate studies removal, 4652 papers were screened based on their abstracts by 33 assessors using predefined inclusion criteria. A total of 758 papers were retained for data extraction. The percentage of papers for each animal category were as follows: cattle (67%), pigs (12.8%), poultry (8.6%), and small ruminants (8.6%). The most common measured indicators were body posture/movement (25.89%), rumination (24.1%), and behavioural synchrony (8.67%), while all other indicators individually accounted for less than 8% of the studies. Hardware-based technologies predominated (82.5%), in which the validation relied mainly on internal procedures (35.6%) or human observations (52%) as a gold standard. Around half of the identified technologies were considered applicable under commercial farm conditions by the assessors. Overall, the results indicate that some PAW indicators can be assessed with the help of available technology. However, most of the measurements assessed general welfare or behaviour, not specifically PAW. Defining measurable PAW indicators is needed to develop practical methodologies and technological systems. Furthermore, wider application across livestock species and stronger external validation is required to support robust on-farm use and provide reliable outputs.

Identifying animal-based indicators for positive animal welfare in laying hens

M. Booijen[1], F. Hoorweg[1], M. Wolthuis-Fillerup[1], M. Van Der Sluis[2], J. E. Doornweerd[2], T. Johansson[1], A. Van Dolderen[1]

[1] Wageningen University & Research, Animal Health and Welfare, De Elst 1, 6708WD Wageningen, Netherlands, [2] Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6708PB Wageningen, Netherlands

Animal welfare can be defined as the experience of life viewed by the animal itself. Factors that affect welfare are those which create positive or negative mental states. The focus in animal welfare science has accordingly shifted from merely minimising suffering to also promoting positive experiences and a good life. It has even been suggested that positive experiences and their benefits are crucial to animal welfare. Following, there is an interest in objectively measuring positive animal welfare (PAW). However, feasible indicators for measuring PAW on farm are still needed. The aim of this study was therefore to identify behavioural indicators related to positive experiences in brown laying hens and it was hypothesized that hens would show different types, duration or sequence of behaviour during and/or after receiving a highly valued resource than control animals. To test the hypothesis, an experiment was carried out with 12 laying hens receiving mealworms to evoke a positive mental state and 12 control hens not receiving a resource. The experimental arena consisted of a front and back area divided by a door. The hens were placed in the front part of the pen, the door was opened after 10 seconds and hens were able to move to the back area where they had access to the resource. All hens were tested three times in pairs, while receiving a different resource each time 1.) freely available mealworms, 2.) mealworms in a snack ball or 3.) mealworms in litter. Test and control hens remained in the arena for a total of 20 minutes. Control hens did have access to the back area, but did not receive the different resources. All laying hens were trained before testing began to ensure habituation to the arena. Additionally, test hens passed the training when showing anticipatory behaviour and ability to move through the door. Behavioural observations at hen level were executed continuously from video recordings. Furthermore, tail movements and position were scored. Currently, the videos are being analysed and this data will be statistically analysed afterwards. Pre-liminary results indicate that the tail movements and tail position are linked to availability of the resource and differ per type of resource. Furthermore, duration and frequency of behaviour seems to differ per resource. Future research should focus on testing validity of found indicators on farm. The finalized results will be presented during the EAAP conference. This work was co-funded by the European Union's Horizon Europe Project 101136346 European Partnership on Animal Health and Welfare as part of an internal project (SOA13).

Sacred Care and Scientific Compassion: Integrating Positive Animal Welfare into Lifelong Management Systems of Indian Gaushalas

M. A. Karatzia[1]
[1] *ELGO-DIMITRA, Research Institute of Animal Science, Paralimni, 58100 Giannitsa, Greece*

Gaushalas, or cow shelters, have been around for a significant time and have been integrated into the fabric of Hindu religious and ethical philosophies. The Government of India report from 2023 provides a state-by-state breakdown of gaushala density. The highest density can be seen in the northwest and central parts of India: Rajasthan has 2,269 gaushalas, Gujarat has 1,418, Madhya Pradesh has 905, Haryana has 640, and Uttar Pradesh has 582. A slightly lower density can be seen in Punjab with 447, Maharashtra with 222, Karnataka with 220, Himachal Pradesh with 221, Telangana with 175, and Chhattisgarh with 117. Other areas have fewer than 40 or no gaushalas at all. This corresponds with how cattle demographics, religious acceptance, and the demands of caring for old or unproductive animals intersect.Unlike dairy farming, where there is a clear end product with a limited time frame before it is sold or consumed, gaushalas have animals in their care for a much longer time. The focus then changes from the end product to the overall life experience. However, research has shown that there are problems with gaushala management. The common approach is protective and follows the 1960 Prevention of Cruelty to Animals Act. It seeks to ensure survival, provide sufficient food, and prevent slaughter. However, welfare science now suggests that simply not being in pain is not necessarily indicative of good welfare. The Five Domains approach provides a clear structure for welfare assessment. It covers nutrition, environment, health, behavior, and mental state. It can be used to assess positive welfare as well as negative welfare. In gaushala situations, small imbalances in nutrition can have a significant impact over time.This study offers a framework for a norm-based, management-focused approach to integrating PAW into gaushalas. From a farm management perspective, three areas for greatest leverage are: firstly, improving nutrition beyond mere maintenance through forage variety and rumen health; secondly, re-designing the physical space to increase space complexity, provide adequate shade, and support stable social groups; and lastly, adding behavioral activities and providing choices to increase animal agency and positive emotions. Even marginal daily improvements, when multiplied over 3,650–7,300 days of post-productive life, may substantially alter cumulative welfare outcomes.Gaushalas are seen to be hybrid institutions that combine elements of religious obligation or duty (dharma), non-violence or ahiṃsā, and civil society engagement with large-scale herd management. Their ethical legitimacy is strong, though welfare outcomes are variable. Once we think of shelters as dynamic management systems rather than static sanctuaries, the transition from mere protective welfare to positive welfare becomes practically possible. The study's findings suggest that integrating PAW into life-long cattle management is not simply an ethical addition; it is a structural imperative to guarantee that extended life translates into a life worth living.

Effect of enrichment provision and pair-housing on the development of calf locomotor play during the pre-weaning period

M. A. Mason[1], J. D. Bus[1], M. B. Jensen[1]
[1] Aarhus University, Department of Animal and Veterinary Sciences, AU Viborg, Blichers Alle 20, 8830 Tjele, Denmark

Play is an easily recognisable, non-invasive measure of an animal's current affective state, which typically decreases when animals experience threats to welfare (e.g. hunger or pain). However, compared to welfare threats, an empirical link between positive emotions and increased play behaviour in non-human animals is less well established. Therefore, to evaluate the validity of play behaviour as a positive welfare indicator in calves (Bos taurus), we investigated how play changes over the first weeks of life based on whether or not calves were kept in preferred housing conditions. 42 calves in seven blocks of six were housed generally within 24 hrs of birth in individual (7.5x3m) or pair (7.5×4.5m) pens under enriched (with a swinging non-motorised brush and hay net) or control conditions in a 2×2 factorial design (each block featured one pen from each of the four treatments). At weeks 2, 3, 4, 5 and 6 following introduction of the final calf into a given block, 28 calves (one focal calf per pen) were equipped with hind leg-mounted accelerometers (HOBO pendant G data loggers) sampling at 1Hz on the vertical (x-) axis from 05:00-23:00 for two consecutive days (two 18 hr periods). Currently, completeness and quality of accelerometer data records have been verified, and relevant acceleration features calculated (i.e., peak counts at different thresholds, means of highest and lowest values, variance, and several features capturing change between consecutive measurements) at 10 s windows. These features will be compared to play observations coded from video footage taken at week 6 into the experiment, to develop and test an algorithm that can validly detect calf play (one-zero sampling for each 10 s window). From here, we will establish whether this algorithm can also be applied to identify play in calves of younger age cohorts, using video observations taken at week 2. Finally, the validated algorithm will be applied to the full data set (i.e. all calves and age cohorts) to study/compare differences in locomotor play development over the pre-weaning period between our four housing treatments. We predict that calves able to access resources that they prefer and value (enrichment items and companions) will be in a more positive mental state and therefore express higher levels of locomotor play compared to calves in less preferred housing situations. Our findings will be ready to present in September at the EAAP conference. Our research was co-funded by the European Union's Horizon Europe Project 101136346: European Partnership on Animal Health and Welfare (EUP AH&W) as part of SOA13: Assessment of positive welfare defining animal-based measures.

Black soldier fly larvae in poultry feed: nutrition, functionality, and challenges for sustainable production in a circular economy

G. Daş[1], S. M. M. Seyedalmoosavi[2], L. Syahrulawal[1], M. Mielenz[1], B. Kuhla[1], J. Zentek[3], C. C. Metges[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] Leibniz Institute for Agricultural Engineering and Bioeconomy (ATB), Max-Eyth-Allee 100, 14469 Potsdam, Germany, [3] Freie Universität Berlin, Department of Veterinary Medicine, Institute of Animal Nutrition, Königin-Luise-Str. 49, 14195 Berlin, Germany

Insects constitute a promising source of animal-derived protein, fat, and minerals for poultry nutrition. Among the EU-approved insect species, black soldier fly larvae (BSFL) are of particular interest due to their comparatively high nutrient and energy conversion efficiency as well as their remarkable flexibility regarding rearing substrates. In addition, functional properties such as antimicrobial peptides, lauric acid, chitin, and mineral accumulation, together with their potential use as edible environmental enrichment for poultry, further enhance the appeal of BSFL as feed ingredient. BSFL-derived products can at least partially replace conventional protein sources without compromising growth performance, feed efficiency, or product quality in both broilers and laying hens. However, optimal inclusion levels of BSFL in poultry diets remain under discussion, as studies have used non-standardized BSFL products (e.g., defatted vs full-fat meal, dried or live larvae) with variable protein and fat contents, which influence amino acid and energy availability, digestibility, and consequently animal performance. Beyond their nutritional value, BSFL contribute to circular bioeconomy strategies through efficient biomass conversion and reduced reliance on resource-intensive feed ingredients. Nevertheless, the economic and ecological sustainability of BSFL production as poultry feed strongly depends on the availability of substrates that have little or no potential for direct use in food or feed production. From a systems perspective, BSFL should exhibit substantially higher nutrient and energy conversion efficiencies than poultry to justify their production on high-quality substrates. This limitation arises from the so-called double transformation of nutrients and energy, whereby additional nutrient and energy losses occur during insect production prior to their use as livestock feed. The production of BSFL as poultry feed involves a double biological conversion, and the associated trophic losses highlight the need to rely primarily on substrates with low or no value for direct human or livestock consumption. Consequently, nutrients for BSFL should primarily originate from biomass that is inedible to humans and livestock species. This prioritization of biomass use underscores the need for innovative technologies to exploit sustainable substrate sources for BSFL production. The first aim of this work is to provide an overview of the nutritional quality of BSFL protein, fat, and minerals, and to evaluate nutritional, physiological, health, and behavioural responses of poultry to dietary intake of BSFL. Second, challenges related to sustainable BSFL production on low-quality substrates, which are upgraded through technological approaches (e.g., fermentation and other pre-treatments) are discussed. In this context, ongoing activities within the newly launched EU-wide project NUTRIFEEDS aimed at developing sustainable BSFL-based feeding strategies for poultry will be presented.

Dietary inclusion of Hermetia illucens oil in dairy cows: effects on rumen microbiota and fermentation parameters

L. Rastello[1], S. Colombini[2], I. Ferrocino[3], X. Dai[2], P. Toral[4], M. Battelli[2], M. Coppa[3], L. Gasco[3], M. Gerbelle[5], L. Vernetti-Prot[5], A. Galli[6], C. Trespeuch[7], M. Renna[1]

Agricultural and Environmental Sciences, Via Celoria 2, 20133 Milan, Italy, [3] University of Turin, Dept. Agricultural, Forest and Food Sciences, L.go Braccini 2, 10095 Grugliasco, Italy, [4] Instituto de Ganadería de Montaña (CSIC-ULE), Finca Marzanas S/N, 24346 Grulleros, Spain, [5] Institut Agricole Régional, La Rochère 1/A, 11100 Aosta, Italy, [6] Ferrero Mangimi SpA, Via Fornace 15, 12060 Farigliano, Italy, [7] Mutatec, Chemin du Mitan, 84300 Cavaillon, France

Including lipids in the diet of dairy cows is a common practice aimed at increasing the dietary energy density while also modulating rumen microbiota to reduce CH4 emissions. However, traditional lipid sources are often criticized for their high environmental footprint, highlighting the need for more sustainable alternatives. This study aimed to assess whether the oil extracted from Hermetia illucens (HIO) larvae, which has a potentially lower footprint, could serve as a viable alternative to fractionated palm oil (FPO) in dairy cow nutrition without causing negative effects on rumen fermentation parameters and microbiota in dairy cows. A 50-day trial was conducted with two equivalent groups of thirteen lactating Valdostana Red Pied cows each. The two groups were fed a diet characterized by a 70:30 forage:concentrate ratio, which differed only for the concentrate lipid source, being either HIO or FPO (0.9% of the diet DM). Individual rumen fluid samples were collected on the last day of the trial. In vivo analysis included microbiota composition (DNA sequencing), and protozoal counts. Rumen fluids were also used as inocula for in vitro incubations (24 h) to determine total gas and CH4 production, pH, ammonia and volatile fatty acids. Statistical analysis was performed using the MIXED procedure of SAS software ($P<0.05$). Spearman correlation evaluated associations between bacterial genera and fermentation profile. No differences in the tested fermentation parameters were observed, with the only exception being butyrate production, higher with the HIO diet compared to the FPO diet (16.9 vs. 12.0 mol/100 mol, respectively; $P<0.001$). This higher production was concomitant with a greater abundance of large Entodiniomorphs protozoa (9.14×103 cells/mL vs. 1.17×103 cells/mL in the HIO group and FPO group, respectively; $P=0.001$), which are known to directly contribute to butyrate production. Interestingly, C12:0, the main individual fatty acid in HIO, is known for its antimicrobial properties and therefore a protozoal reduction was expected. However, literature suggests this effect being dose dependent. Consistent with a higher abundance of protozoa, an enrichment in other archaeal or bacteria genera typically associated with them, such as Methanobrevibacter ($P<0.01$) and Treponema ($P<0.05$), was observed in rumen fluid of HIO-fed animals. To add, several fiber-degrading Firmicutes, including Pseudobutyrivibrio, were less abundant in the HIO group ($P<0.05$). No differences in α- or β-diversity were observed between the two groups ($P>0.05$). Spearman correlation analysis further revealed positive associations between C12:0 intake and Methanobrevibacter and Treponema abundance ($P<0.05$), suggesting that the C12:0 content of HIO promoted the observed microbial shifts. These findings highlight that a low dose of HIO only exerts modest effects on rumen fermentation parameters and microbiota shifts, suggesting the possible use of HIO in dairy cow diets as an innovative and alternative lipid source. Research supported by Hi-Ga project; Green Era Hub on Agri Food and Biotechnology.

Black soldier fly larvae (Hermetia illucens) fat as an alternative fat source to coconut fat in milk replacer for calves

N. S. Stöhr[1], M. H. Ghaffari[2], J. Hayer[3], T. Scheu[3], R. Schemmer[4], T. Priesmann[5], C. Koch[1], G. Dusel[1]
[1] University of Applied Sciences Bingen, Department of Agriculture / Animal Nutrition and Health, Berlinstr. 109, 55411 Bingen am Rhein, Germany, [2] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [3] Lehr- und Versuchsanstalt Hofgut Neumühle, Neumühle 1, 67728 Münchweiler an der Alsenz, Germany, [4] BEWITAL agri GmbH & Co. KG, Industriestr. 10, 46354 Südlohn-Oeding, Germany, [5] Dienstleistungszentrum ländlicher Raum (DLR) Eifel, Westpark 11, 54634 Bitburg, Germany

The increasing global demand for food and growing competition for natural resources necessitate the development of sustainable feed alternatives in livestock farming. Insect-derived ingredients have emerged as promising feed sources due to their efficient nutrient conversion and potential for circular bioeconomy applications. Within the European Union, processed animal proteins from insects were approved for poultry and pig diets, whereas insect protein remains restricted for ruminants' diet. However, insect-derived fats are permitted in calf nutrition. Black soldier fly larvae (BSFL, Hermetia illucens) represent a promising fat source due to their ability to efficiently convert organic waste into high-quality biomass and offer a local alternative to conventional fats such as palm and coconut fat. Compared to coconut fat, which is largely imported from tropical regions, BSFL fat can be produced regionally, reducing environmental impact while maintaining nutritional value. BSFL fat is characterized by a high proportion of saturated fatty acids, particularly lauric acid, resulting in a fatty acid profile similar to that of coconut fat, which is widely used in calf milk replacer (MR) formulations. While BSFL products have been successfully integrated into poultry, fish, and swine diets, their application in calf nutrition remains largely unexplored. This study evaluated the effect of feeding MR formulated with BSFL fat as an alternative fat source for calves. A total of 24 male Simmental calves (33.5 days of age; initial body weight = 76.0 kg) were allocated equally to two dietary treatments (n = 12 calves per treatment): CON = MR containing 50% sunflower oil and 50% coconut fat as the fat source; LAR = coconut fat completely replaced by BSFL fat. Both MR formulations were isoenergetic and isonitrogenous. Calves were fed for 63 days using an automatic MR and concentrate feeder equipped with transponders to allow individual intake recording. The feeding program consisted of five weeks of intensive MR feeding (maximum 12 L/calf/day), followed by four weeks of gradual weaning to 2 L/calf/day in the last week. Concentrate feed was available at 9.8 kg/calf/day, and water and hay were available ad libitum. Calves were housed in one group per treatment (12 calves per pen) in a naturally ventilated barn with straw bedding. Body weight (BW) and health parameters (e.g., fecal consistency score) were recorded weekly. Data were analyzed using one-way ANOVA ($p < 0.05$). The results of the study showed no significant difference in BW or average daily gain between the two dietary treatments. However, LAR-fed calves had a higher MR intake than CON, with significant differences observed at week 3, while concentrate feed intake was significantly lower in LAR calves than in CON calves at weeks 8 and 9. This resulted in a significantly reduced total dry matter intake and lower metabolizable energy intake in LAR calves. Feeding behavior showed no significant differences between diets for rewarded visits, unrewarded visits, or total visits, while drinking speed (mL/min) was significantly higher in LAR compared to CON. There was no significant effect of dietary treatment on fecal consistency score.

Influence of chitinase inclusion level and application method on the digestibility and utilization of black soldier fly meal in juvenile rainbow trout

S. Bellezza Oddon[1], A. A. Melis[1], I. Biasato[1], K. Loufi[1], Z. Loiotine[1], M. Van Spankeren[2], L. De Jong[2], L. Gasco[1]
[1] University of Turin, Department of Agricultural, Forest and Food Sciences, Largo Paolo Braccini, 2, 10095 Grugliasco, Italy, [2] Protix B.V., Magistratenlaan 16, 5223 MD 's-Hertogenbosch, Netherlands

The inclusion of black soldier fly (BSF) meal in rainbow trout (Oncorhynchus mykiss) diets has been widely investigated, generally showing positive effects on growth performance. However, nutrient digestibility may vary depending on the type and processing of the insect meal. Therefore, strategies to enhance BSF meal utilization require further investigation. The present study aimed to evaluate the effects of different chitinase inclusion levels and enzyme application methods in juvenile rainbow trout diets containing BSF meal. A basal control diet including 10% BSF meal was formulated (C). Chitinase (Aspergillus niger) was directly incorporated into the diets at increasing inclusion levels of 0.25%, 0.50%, and 0.75% (CH1, CH2, and CH3, respectively). In addition, a pre-treated BSF meal subjected simultaneously to enzymatic digestion with 0.75% of chitinase and heat treatment was evaluated (PRO2). To distinguish the effects of thermal processing from enzymatic activity, a heat-treated BSF meal without chitinase was included as a separate treatment (PRO1). At the beginning of the trial, a total of 480 fish (16 g ± 0.13) were allocated to 24 tanks, which were then randomly assigned to the different dietary treatments. Fish were weighed every two weeks to monitor growth curve. The trial was ended when the fish had tripled their initial body weight. To determine diet digestibility, Celite was included in the feed as an inert marker at 1%. Feces were collected twice daily over a 7-hour period for 35 days by siphoning the tanks and subsequently filtering the recovered material. The evaluated parameters included survival rate (SR), final body weight (FBW), feed conversion ratio (FCR), and apparent digestibility coefficients of dry matter (ADCDM), crude protein (ADCCP), and gross energy (ADCGE). Data were analyzed using one-way ANOVA, followed by Tukey's post hoc test (SPSS v28.0; $p<0.05$). SR was not affected by the dietary treatments ($p>0.05$). However, FBW and FCR were significantly improved in the CH1 group compared to CH3 ($p<0.05$), while the other groups showed comparable results ($p>0.05$). ADCDM and ADCGE were not influenced by the experimental diets ($p>0.05$). In contrast, the ADCCP was significantly higher in the control group compared to all other treatments ($p=0.01$). Overall, chitinase supplementation did not produce consistent improvements in growth performance or nutrient digestibility compared to the control diet, while the moderate supplementation level showed slightly better growth performance than the highest level. The results indicate that 0.75% of chitinase inclusion may exert a negative influence on growth performance than 0.25% level, without providing digestibility benefits. The HiGa project is supported within the Green Era Hub call by the Green Development and Demonstration Programme, GUDP, under the Italian Ministry of Agriculture, Food Sovereignty and Forests (MASAF) (CUP: GASL_RIC_COMP_24_02).

Black soldier fly larvae (Hermetia illucens) meal as an alternative protein source in organic free-range laying hen production

N. S. Stöhr[1], J. G. Brettschneider[1], L. Schneider[1], R. Jha[2], G. Dusel[1]
[1] University of Applied Sciences, Department of Agriculture / Animal Nutrition and Health, Berlinstr. 109, 55411 Bingen am Rhein, Germany, [2] University of Hawaii at Manoa, Dept. of Human Nutrition, Food and Animal Sciences, 1955 East-West Rd., AgSci 216, 96822 Honolulu, HI, United States

With the EU Organic Regulation (EU) 2018/848 requiring 100% organic feed in organic livestock production by 2027, the demand for high-quality, regionally produced, and organic protein sources in Germany is increasing. At the same time, organic egg production faces challenges due to the limited availability and environmental impact of conventional protein sources such as soybean or fish meal. Insects represent a promising alternative because of their high protein quality, efficient resource use, and potential for production within circular agricultural systems. This study investigated the effects of feeding black soldier fly larvae (BSFL) meal as a substitute for soybean in organic diets on production performance and egg quality of Lohmann Brown laying hens. A total of 160 18-week-old laying hens were randomly assigned to two dietary treatments (4 pens/treatment, 20 hens/pen, free-range system). The treatments consisted of an soy-based control diet (SOY) and a BSFL meal-based diet (LAR). Hens in the SOY group received a commercial organic diet containing 13.5% soy. In the LAR treatment, soy was completely replaced by BSFL meal. After a two-week adaptation, birds were fed for 14 weeks (20-34 weeks of age). Body weight was recorded at week 20, 25, and 34 weeks of age, and feed intake was measured weekly. Egg production was recorded daily to calculate weekly percentage laying performance. At the end of the experimental period, 10 eggs per pen (40 eggs per treatment) were collected for egg quality analysis. Data were analyzed using one-way ANOVA ($p<0.05$). Feeding BSFL meal in organic diets did not affect hens´ production performance. During the whole experimental period, no significant differences were observed between treatments in average daily feed intake (SOY=109 vs. LAR=110g/hen/day; $p>0.05$), percentage laying performance (SOY=90.9 vs LAR=89.7%; $p>0.05$), individual egg weight (SOY=57.8 vs. LAR=58.5g/egg; $p>0.05$), or feed conversion ratio (SOY=2.07 vs. LAR=2.11g feed/g egg mass; $p>0.05$). Egg quality analysis showed that eggs from LAR-fed hens were longer (SOY=54.7 vs. LAR=56.1mm; $p<0.01$), resulting in a significantly lower shape index (SOY=80.2 vs. LAR=78.4; $p<0.01$). However, LAR-fed hens produced numerically heavier eggs (SOY=59.6 vs. LAR=60.9g/egg; $p>0.05$), resulting in higher proportion of marketable egg weight classes M and L (SOY: 15% S, 63% M, 23% L, 0% XL vs. LAR: 0% S, 73% M, 25% L, 3% XL), which is of economic relevance. LAR-eggs showed a significantly lower albumen height, resulting in reduced Haugh units (SOY=87.4 vs. LAR=82.3, $p<0.01$). Moreover, LAR-eggs contained a significantly higher yolk proportion (SOY=25.7 vs. LAR=27.2%, $p<0.01$), which was associated with a tendency towards lower albumen (SOY=61.4 vs. LAR=60.3, $p<0.1$) and eggshell proportions (SOY=12.9 vs. LAR=12.5, $p<0.1$). Eggshell breaking strength and thickness were not affected by dietary treatment. However, yolk color, as measured by the DSM ROCHE color fan, was significantly lighter in LAR eggs compared to SOY (SOY=7.1 vs. LAR=6.3, $p<0.01$). In conclusion, replacing soy with BSFL meal represents a suitable and sustainable alternative protein source for laying hens in organic production systems, maintaining productive performance while inducing only minor changes in egg quality characteristics. The study was conducted as part of the EIP-agri project “LARF-Pick” and funded by the Ministry of Economics, Transport, Agriculture, and Viticulture, Rhineland-Palatinate, Germany.

Effects of three feeding strategies based on black soldier fly larvae on gut health and redox status in fast-growing chickens

C. Paës[1], A. E. Abdel-Moneim[2,3], L. A. Guilloteau[2], F. Kempf[4], C. Gérard[2], S. Abousaid[5], V. Tondereau[1,5], V. Bezirard[5], H. Eutamène[1,5], E. Baéza[2], C. Trespeuch[6], P. Belloir[1], B. Méda[2]

[1] EI-PURPAN, Université de Toulouse, 31076 Toulouse, France, [2] INRAE, Université de Tours, BOA, 37380 Nouzilly, France, [3] Biological Applications Department, Nuclear Research Center, Egyptian Atomic Energy Authority, 13759 Cairo, Egypt, [4] INRAE, Université de Tours, ISP, 37380 Nouzilly, France, [5] UMR 1331, Université de Toulouse, EI-PURPAN, ENVT, Toxalim, INRAE, 31300 Toulouse, France, [6] MUTATEC, 1998 Chemin du Mitan, 84300 Cavaillon, France

Black soldier fly (BSF) larvae are a promising alternative protein source for poultry, and have been reported to enhance gut health due to their richness in chitin, lauric acid, and antimicrobial peptides. However, in vivo studies have shown inconsistent health outcomes, likely due to differences in dietary inclusion levels and characteristics of the BSF material used. This study investigated the mechanisms by which three BSF materials affect the systemic and gut health of fast-growing chickens. Two hundred sixty-four day-old Ross 308 male chicks were assigned to one of four experimental diets until d35 (one pen per diet, each bird served as the experimental unit): a control diet (C); a diet with 10% of defatted larvae meal (LM), and two diets associating a deconcentrated pelleted feed with the provision of either live (LL) or dried (DL) BSF larvae, representing 15% of daily dry matter (DM) intake. Daily performance was measured individually using electronic feeders. At d35, 15 birds per diet were randomly selected for plasma, jejunal mucosa, caecal contents, and thigh muscle collection. Gut health was assessed through markers of (1) barrier integrity, absorptive, and immune functions, (2) redox status, and (3) microbiota composition. Jejunal histomorphometry was evaluated by H&E staining. Expression of gut-related genes in the jejunal mucosa was quantified by RT-qPCR. Plasma redox status was determined by measuring total antioxidant capacity and lipid peroxidation (TBARS). Caecal microbiota composition was assessed by sequencing the 16S rRNA V3/V4 region. Data were analysed using One-Way ANOVA followed by post-hoc tests. DL birds showed the lowest growth rate throughout the period ($P<0.001$; -10% compared to C). As a possible compensatory mechanism, these birds had a larger villus surface area ($P<0.01$; +32%<C). Upregulation of nutrient transporter genes (PAT1, SLC7A6, SLC1A1, and SLC5A) in DL birds, compared to C and LM, suggested an adaptive response to lower nutrient availability. However, the upregulation of NF-kB, TNFα, and EXFABP in the DL group ($P<0.05$) indicates a pro-inflammatory gut response. Increased expression of tight junction genes related to paracellular barrier functions (CLDN10, OCLN, TJP2, and MMP2) was also observed in the jejunal mucosa of DL birds ($P<0.05$), compared to C, potentially to counteract inflammation and maintain barrier function. At the systemic level, an increase in plasmatic and leg muscle lipid peroxidation was observed in LL birds compared to C and LM ones ($P<0.01$), with intermediate levels for DL ones, but total antioxidant status remained unchanged among diets. Caecal microbiota beta-diversity metrics were modified, with a significant increase in bacterial symbionts Bacteroides, Lactobacillus, and Ruminococcaceae UCG-005 in LM birds ($P<0.05$). In conclusion, 10% LM reshaped the caecal microbiota profile without impairing growth. In contrast, 15% BSF larvae, particularly dried, triggered a pro-inflammatory intestinal response and systemic oxidative stress, necessitating compensatory mechanisms in the gut. Further research is needed to identify the specific molecules driving these results to optimize BSF inclusion in poultry diets.

Does gut health have a key role in shaping growth performance in insect-fed broilers?

Gut health is considered a key driver of growth performance in broiler chickens, but integrated analytical approaches encompassing gut microbiome, histomorphometry, and mucin histochemistry analyses for the identification of specific microbial, metabolic, and structural intestinal biomarkers associated with variations in bird productive performance are still very limited. The present study investigated the relationships among comprehensive gut health parameters and growth performance in broiler chickens fed diets containing Hermetia illucens (HI) and Tenebrio molitor (TM) meals at 5% or 10% inclusion levels, either as single ingredients or in a 1:1 mixture. A 37-day growth trial was conducted using 420 male Ross 308 broiler chicks randomly assigned to seven dietary treatments (6 replicates/diet, 10 birds/replicate): C (control), HI5 (5% HI), HI10 (10% HI), TM5 (5% TM), TM10 (10% TM), MIX5 (5% MIX), and MIX10 (10% MIX). An integrated analytical approach encompassing caecal microbiome characterization (amplicon sequencing, shotgun metagenomics and targeted metabolomics), and jejunal histomorphometry and mucin histochemistry was employed to identify microbial, metabolic, and structural intestinal biomarkers mechanistically explaining variations in bird productive performance. High-performing birds (MIX5 and TM5) exhibited caecal microbiomes enriched in short-chain fatty acids-producing taxa, including Veillonellaceae, Butyricicoccus, and Limosilactobacillus crispatus, which correlated positively ($P<0.05$) with feed conversion rato (FCR), average daily gain (ADG), and average daily feed intake (ADFI). These groups demonstrated favorable metabolomic shifts, including increased concentrations of dopamine, tyramine, malic acid, and orotic acid, alongside reduced levels of metabolic dysfunction markers such as 3-deoxyglucosone and hexanoylcarnitine ($P<0.05$). The preservation of gut mucin balance, particularly acidic sulphated mucins, was strongly associated with higher ADFI ($P<0.01$), improved FCR ($P<0.05$), and greater body weight ($P<0.05$). Conversely, low-performing birds (MIX10 and HI10) displayed gut microbiome signatures dominated by Ruminococcaceae, Alistipes, and L-Eubacterium, which are taxa negatively correlated with feed efficiency and associated with altered purine metabolism ($P<0.05$). These microbial shifts coincided with compromised gut morphology, including tendency towards reduced villus height in MIX10 birds ($P=0.070$) and decreased mucosal and muscular layers ($P<0.01$), which correlated positively with ADG ($P<0.05$) and negatively with FCR ($P<0.05$). The TM10 diet maintained stable performance despite high inclusion level, potentially due to beneficial taxa (Limosilactobacillus crispatus and Tyzzerella) and marked reduction in Campylobacter jejuni abundance (false discovery rate <0.05), alongside decreased antimicrobial resistance genes ($P<0.05$). Jejunal inflammation remained unaffected across treatments, indicating that growth modulation was primarily driven by microbiome–mucosal interactions rather than inflammatory processes. These results underscore the complexity of host–microbiome–diet interactions and identify specific microbial taxa (Butyricicoccus, Veillonellaceae and Limosilactobacillus crispatus), metabolites (dopamine and tyramine), and mucosal features (villus height, mucosal and muscular layers and acidic mucin composition) as potential biomarkers of optimal performance in broilers fed insect-based diets, suggesting that 5% inclusion levels optimize gut functionality and productive outcomes.

Effect of black soldier fly larvae oil and feed withdrawal on meat quality parameters in broilers subjected to cyclic heat stress during the final growth period

Puerta de Hierro 2, 28040 Madrid, Spain

Medium-chain fatty acids (MCFAs) are rapidly oxidized, less susceptible to lipid peroxidation, and provide readily available energy, which may help preserve oxidative stability in broiler muscle under heat stress (HS). In addition, controlled feed withdrawal (FW) during peak heat periods may reduce metabolic heat production, further protecting muscle from oxidative damage. It is hypothesized that the inclusion of black soldier fly larvae oil (BSFO) as a lipid source rich in MCFAs, together with a strategy of FW may attenuate HS induced deterioration of broiler meat quality. A total of 540 one-day-old Cobb 500 broilers were randomly allocated to 54 pens and fed the same commercial diets from 1 to 20 days of age. Broilers were then divided into 6 groups (9 replicates per treatment; 10 birds per pen) following a completely randomized design. Two experimental groups were kept under thermoneutral (TN) conditions and fed isoenergetic (3,079 kcal/kg) and isoproteic (19% CP) corn soybean diets supplemented with 5.5% soybean oil (SBO) or BSFO from 22 to 35 days of age. The other four groups were also housed under TN conditions until day 29, then exposed to cyclic HS (temperature-humidity index 80) for 6 hours daily from days 30 to 35. These birds received SBO or BSFO diets, and two of the groups additionally underwent a 6-hour FW during the peak HS period. Birds were euthanized using CO_2, and carcasses were chilled at 1 °C for 2 h. Breast samples were collected from 9 birds per treatment then stored at 4 °C under LED lighting to simulate commercial retail display conditions. Water-holding capacity (WHC) was determined at 72 h postmortem, whereas color stability and lipid oxidation measured by thiobarbituric acid reactive substances (TBARS) were evaluated during refrigerated storage (4 °C) at days 1, 4, and 7. Main effects stress (TN or cyclic HS), fat source (SBO or BSFO), feed withdrawal and storage time for color and TBARS and their interactionswere analysed with orthogonal contrasts using the Mixed procedure of SAS. WHC was significantly higher in meat from birds under TN conditions than under HS ($P < 0.001$), with no effect of oil type or FW. Meat lightness (L*) was also higher in TN conditions compared with HS ($P = 0.035$). Meat redness (a*) tended to increase in the BSFO groups subjected to FW under HS ($P = 0.059$), whereas yellowness (b*) was higher in treatments with FW, regardless of oil type ($P = 0.035$). Chroma (intensity of the color) also increased in meat from birds under FW ($P = 0.018$) and showed a triple interaction among HS, oil source, and FW, with the highest values observed in birds fed BSFO and subjected to FW under HS ($P = 0.042$). TBARS values did not show significant differences, although they increased numerically over time. In conclusion, HS during the finisher period impaired breast meat quality, reducing both WHC and lightness. The inclusion of BSFO combined with FW produced responses comparable to soybean oil under heat stress conditions, although specific changes in redness and chroma indicate a potential positive influence on color-related traits. This research was supported by grant PID2023-149145OB-I00 funded by MICIU/AEI/10.13039/501100011033 and ERDF/EU.

Beyond soybean meal: alternative grain legumes in diets for broiler chickens

F. Bordignon[1], M. Pravato[1], M. Molin[1], G. Zorzi[1], C. Maucieri[1], G. Xiccato[1], V. Giannini[1], A. Trocino[1,2]
[1] University of Padova, Department of Agronomy, Food, Natural resources, Animals and Environment (DAFNAE), Viale dell'Università 16, 35020 Legnaro (PD), Italy, [2] University of Padova, Department of Comparative Biomedicine and Food Science (BCA), Viale dell'Università 16, 35020 Legnaro (PD), Italy

In the EU, recent efforts to reduce soybean meal use in poultry diets are driven by import reliance and environmental sustainability, while supporting the use of local protein sources. Among these alternatives, grain legumes have gained attention, yet their effects on chicken performance and meat traits remain underexplored. Therefore, this study evaluated the effects of partially replacing soybean meal with legumes (faba bean, Vicia faba var. minor; or white lupin, Lupinus albus) and sunflower meal on the performance, slaughter results, and rheological traits of broiler chickens. From hatch to 36 d of age, a total of 624 male chickens housed in 24 pens (26 birds/pen; 6 pens/treatment) were fed either a commercial soybean-based diet (C) or the same diet including faba bean (F; 90% C + 10% faba bean), lupin (L; 90% C + 10% lupin) or dehulled sunflower meal (S; 90% C + 10% sunflower meal). Slaughter traits, breast myopathy occurrence, and pH, colour, thawing and cooking losses, and shear force of pectoralis major were assessed on 144 birds (6 birds/pen; 36 birds/treatment). Daily weight gain was lower in chickens fed the experimental diets compared with the commercial diet ($p<0.001$), resulting in lower final live weight in chickens fed diet F (−10%) and diets L and S (−14% and −16%, respectively) ($p<0.001$), whereas feed conversion ratio was higher in chickens fed the experimental diets (+14% on average) compared to diet C ($p<0.001$). Carcass yield was unaffected (71.9%, on average), whereas breast yield was highest with diet F (40.4% cold carcass weight), intermediate with diets C and L (39.7 and 38.6%), and lowest with diet S (37.4%) ($p<0.001$). As for breast myopathies, white striping occurrence increased from 2.8% with diet S to 13.9% and 16.7% with diets L and F, reaching the highest rate with diet C (25.0%; $p<0.05$). Wooden breast occurrence increased from 0% with diets L and S to 5.6% with diet F and 13.9% with diet C ($p<0.01$); spaghetti meat occurrence was not affected by diet (1.4%; $p=0.42$). Regarding meat quality, p. major pH was lower (−3%) and lightness (L*) higher (+6%) with diet S compared with diet C ($p<0.001$), whereas yellowness (b*) was lowest with diet F and highest with diet S ($p<0.001$). No significant effects were observed for redness (a*), thawing losses (13%), cooking losses (25%), or shear force (1.95 kg/g). In conclusion, partial replacement of soybean meal with grain legumes or sunflower meal resulted in reduced growth performance, with the faba bean diet being closer to the commercial diet than the other experimental diets. The lower growth rate associated with partial soybean meal replacement likely contributed to reduced white striping and wooden breast occurrence, while only minor changes were observed in meat quality traits. This study was funded by the Project “Strategie di adattamento ai cambiamenti climatici: introduzione e valorizzazione nell’areale veneto di nuove leguminose per l’alimentazione umana e animale”, offered by the University of Padova, DAFNAE Department (Reference: 2024DAFNAE1SIDPROGETTI-00026).

Programmable automated dispenser for high-frequency delivery of dried black soldier fly larvae as behavioural enrichment in broilers

F. Sammo[1], M. Seehaus[1], C. Manteuffel[1], G. Daş[1], J. Langbein[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany

Fast-growing broilers exhibit decreased locomotor activity, which is associated with impaired welfare and leg health. Provision of black soldier fly larvae (BSFL) has been shown to stimulate foraging behaviour and increase activity, but these effects are short-lived when larvae are offered infrequently. Sustained behavioural stimulation requires repeated delivery of small quantities throughout the day, which is difficult to manage manually. Accurate timing and portion control are therefore essential for using BSFL as an edible enrichment in a way that supports both locomotion and welfare. The objective of this study was to develop and technically validate a programmable dispenser capable of delivering dried BSFL frequently and on a set schedule in broiler barns. It was hypothesised that a network-synchronised dispenser would provide accurate and reliable BSFL delivery during the trial. The dispenser had a rotating disc with 41 compartments, each holding a prefilled amount of dried BSFL for 40 feeding portions. A stepper motor ensured accurate movement and portion release. Feeding events were controlled by a microcontroller-based unit, with programmable parameters adjustable via a configuration file. Synchronisation via Network Time Protocol (NTP) ensured accurate time control, independent of power interruptions. In a pilot experiment, broilers received BSFL approximately 10% of their daily feed intake for a full fattening period of 42 days. The larvae were dispensed at 20-minute intervals from 07:30 (GMT+2) during a 13-hour light period. The system operated semi-autonomously in an experimental rearing pen. The system demonstrated robust mechanical performance, delivering consistent portions with accurate temporal control. The system executed 1,680 feeding events without mechanical failure or considerable time deviation. Broilers consistently approached the dispensing area following release events, indicating acceptance of the BSFL as feed and behavioural enrichment. Activity levels remained elevated throughout the five-week observation period of the six-week trial, with no observable habituation to the repeated feedings. Further analysis is underway to measure the full effects on behaviour and performance. Overall, the developed system represents a practical and scalable technical solution for integrating BSFL into broiler feeding and welfare strategies while enabling long-term enrichment

Italian consumers' concerns about the use of insect-derived products in ruminant feed: evidence from CUB models

G. Mastromonaco[1], V. M. Merlino[1], L. Rastello[2], L. Gasco[1], S. Massaglia[1], M. Renna[2]
[1] University of Turin, Dept. Agricultural, Forest and Food Sciences, L.go Braccini 2, 10095 Grugliasco, Italy, [2] University of Turin, Dept. Veterinary Sciences, L.go Braccini 2, 10095 Grugliasco, Italy

The transition towards more sustainable livestock systems requires alternative protein and lipid sources that can reduce environmental pressure and competition between food and feed. Due to their nutritional value and resource efficiency, insects are increasingly recognised as promising feed ingredients. However, despite regulatory developments within the European Union, the use of insect-derived products in ruminant feeding remains limited and could raise specific consumer concerns that might hinder market development. Understanding the structure and determinants of these concerns is relevant for the livestock sector. This study tests two hypotheses: (H1) that Italian consumers express significant concerns about the use of insect-derived products in ruminant diets, but with varying levels of uncertainty in their responses; and (H2) that the intensity of concern and associated uncertainty vary according to socio-demographic characteristics. Data were collected through a survey of 1,040 Italian consumers. Respondents evaluated eight items relating to their level of concern using a 7-point Likert scale (1 = "not at all concerned"; 7 = "extremely concerned"). The items covered inadequate communication to consumers, traceability, hygiene and safety standards, food price, labelling transparency, availability of insects, insect rearing practices and insect processing methods. CUB (Combination of a discrete Uniform and a shifted Binomial distribution) models were estimated via maximum likelihood to distinguish the "feeling" component (systematic inclination towards higher concern levels) from the "uncertainty" component (random response behaviour). The models were first fitted to the overall sample and were then extended to include age and degree of urbanisation (continuous covariates), the statistical significance of which was tested within both components. The results confirmed H1: very high levels of concern emerged for all items (1 – ^ > 0.80), except for sufficient insect availability (1 – ^ = 0.04). Uncertainty parameters were consistently high (1 – ^ > 0.70), indicating widespread hesitation or limited knowledge about this innovation. Regarding H2, age was found to significantly affect all items: concern increased with age, while uncertainty decreased. This suggests that older consumers have more defined attitudes. Urbanisation had different effects: higher levels of urbanisation were associated with greater concern about communication, traceability, and labelling transparency, whereas lower levels of urbanisation were linked to higher concern about insect availability and processing methods. A significant effect of urbanisation on uncertainty emerged only for insect processing methods, with uncertainty increasing in more urban contexts. Overall, the findings consistently show high levels of concern regarding the use of insect-derived products in ruminant feeding, and confirm that both the intensity of concern and the uncertainty of responses are systematically shaped by socio-demographic factors. The high uncertainty parameters are consistent with the risk perception and knowledge gap dynamics that are typically associated with novel feed innovations. These results highlight the importance of transparent communication and evidence-based information strategies in supporting the acceptance of sustainable feed solutions in the ruminant sector. Protein-rich, locally sourced feed ingredients efficiently utilized by young chicks

M. Traineau[1], J. Danel[2], I. De La Borde[3], P. Carre[3], M. Vilarino[1]
[1] ARVALIS, 2 Pouline, 41100 Villerable, France, [2] ARVALIS, rue de l'étang gran castel, 56800 Ploermel, France, [3] Terres Inovia, 11 rue Monge, Parc industriel, 33600 Pessac, France

As part of the CASDAR PRESAJE project, which aims to improve our understanding of the mechanisms related to chick (0-10 old days) nutrition and health, the hypothesis that early-life digestive health may be improved by reducing dietary protein intake during the first day's post-hatch was investigated. In this context, the use of locally sourced feedstuffs that are lower in protein and richer in fibre as alternatives to soybean meal could represent a viable solution. Such an adapted starter diet would facilitate the transition to a more diversified diet during the growth phase. However, scientific references regarding the digestive utilization of raw materials by very young animals remain infrequent. For this reason, ARVALIS conducted several trials to evaluate the digestibility of various high-protein raw materials (HPRM) and thereby determine their nutritional value (energy, protein, starch, amino acids). Ten raw materials were evaluated in ROSS 308 and the nutritional values were obtained by difference calculation using the values of a complementary diet. This one was given alone for several birds and mixed with the tested raw materials for the other birds. The digestibility balance was conducted over three days, from day 5 to day 8. At this age, excretion levels are very low; therefore, animals were housed in pairs. Given the low amount of excreta of the young chicks, their chemical composition was predicted using Near-Infrared Spectroscopy (NIRS), based on calibrations developed by ARVALIS. Amino acid analyses were performed at the faecal level, whereas amino acid digestibility is usually assessed either in caecectomized roosters or through ileal sampling in chickens. This methodological choice was deliberate, as we consider the hypothesis of a negligible effect of caecal modifications at this age to be plausible. In comparison with defatted soybean meal (SBMdef), several expeller meals – two rapeseed expeller meals (RSMexp), two sunflower expeller meal (SFMexp), and two soybean expeller meals (SBMexp) – were assessed, along with dehulled faba beans (FBdeh) and peas (Pdeh) and toasted soybean seeds (SBStos). Across all tested HPRM, crude protein content ranged from 23 (Pdeh) to 49% DM (SMexp), and NDF levels ranged from 7.8 (FBdeh) to 25% DM (RSMexp and SFMexp). Regarding apparent crude protein digestibility, the best-utilized HPRM were FBdeh (92.3%), SBStos (88.3%), and both SBMexp samples (88.1% on average). Semi-dehulled RSMexp showed the lowest nitrogen digestibility (75.3%). Energy utilization of these HPRM ranged from approximately 2000 kcal/kg DM for SFMexp and semi-dehulled RSMexp to 3748 kcal/kg DM for toasted soybean seeds. For the use of a SBMdef, the impact of a higher degree of dehulling (90% versus 60%) resulted in an improvement in AMEn values of 209 kcal/kg DM, along with increases of 9.1 points in nitrogen apparent digestibility and 2.0 points in energy apparent digestibility. Regarding amino acid digestibility, and lysine in particular, the highest values were observed for FBdeh (94.5%) and for one RSMexp (91.6%), whereas the lowest value was recorded for semi-dehulled RSMexp (78%). These results clearly demonstrate the large diversity of HPRM, many of which are efficiently utilized by very young birds and could therefore be incorporated into starter diet formulations for chicks, with the objective of promoting adaptation to diverse and locally sourced feedstuffs during the starter period. These reference values were used to formulate diets in performance trials.

Impact of BSF Larvae Inclusion on Pig Growth

A. C. G. Monteiro[1], T. Mariano[1], R. Pereira[1], R. Fortunato[2], D. Murta[3,5], V. Pinheiro[4], D. Monteiro[4]
[1] FeedInov CoLAB, Av. Prof. Doutor Vaz Portugal, 2005-424 Vale de Santarém, Portugal, [2] Rações Zêzere, S.A., Rua António Teixeira Antunes nº 1269, 2240-037 Ferreira do Zêzere, Portugal, [3] Ingredient Odyssey, R. Eng. Albertino Filipe Pisca Eugénio 152, 2005-002 Santarém, Portugal, [4] Universidade de Trás-os-Montes e Alto Douro, Quinta dos Prados, 5000-081 Vila Real, Portugal, [5] Egas Moniz School of Health & Science, Egas Moniz Center for Interdisciplinary Research (CiiEM), Campus Universitário, Quinta da Granja, 2829 - 511 Caparica, Portugal

The growth of the world's population results in an increased demand for animal products, placing increasing pressure on conventional feed ingredients such as soybean meal and fish meal. The use of insect meal is an opportunity to reduce the pressure on raw materials for animal feed and "Food vs Feed" competition, leveraging a new sector with great potential. This study is being conducted under the Mobilizing Agenda InsectERA (AAC nº02/C05-i01/2022). The study aims to evaluate the added value of defatted BSF larvae meal in growing pigs feed, considering zootechnical performance. The trial was conducted in the UTAD facilities, and was divided in two phases: In the 1st phase 18 litters were selected (6 replicates/treatment; 6 animals/replicate), from which 72 male piglets were selected for the 2nd phase. Piglets' average weight was 3.2 kg at 8 days of age.The 2nd phase of the trial was divided in two sub-phases:from 28 to 42 days (pre-starter diet). Each treatment had 8 replicates for consumption (measurements by pen; 3 animals/pen) and 24 replicates for growth (measurements by animal; 24 animals). Afterwards 8 animals per treatment were slaughtered. This data was presented at EAAP Annual Meeting in 2025.from 42 to 63 days (starter diet). Each treatment had 8 replicates for consumption (pens) and 16 replicates for growth (animals). A total of 48 growing pigs with an average initial body weight of 12.104 kg were distributed to three feeding groups, Control (0% BSF larvae meal), T2 (2.5% BSF larvae meal) and T3 (5.0% BSF larvae meal). Diets (starter diet) were isonitrogenous and isoenergetic.The measurements were individual live weight (LW), individual average daily feed intake (ADFI) of feed, average daily gain (ADG), feed conversion ratio (FCR), morbidity and mortality during the period of the trial. There were no differences in LW, at the end of this phase of the trial, which averaged 25.008 kg. The ADFI, ADG and the FCR at this stage did not show significant differences between the experimental treatments, either over the weeks or over the entire period, averaging 0.946 kg/day, 0.6149 kg and 1.549, respectively. As conclusion we realised that the inclusion of 2.5% and 5% in the starter diet had no relevant positive or negative effects on the productive response of piglets under the conditions of our trial.

Effects of Replacing Plasma Meal with Defatted Black Soldier Fly (Hermetia illucens) Larva Meal on Post-Weaning Piglet Performance, Blood Parameters, and Histopathology

M. Parreiras[1,2,3,4], V. Pinheiro[1,2,4], O. Moreira[3,4], D. Monteiro[1,2,4]
[1] University of Trás-os-Montes and Alto Douro, Animal science, Quinta dos Prados, 5000-801 Vila Real, Portugal, [2] Center for Animal Science and Veterinary Medicine, Animal science, Quinta dos Prados, 5000-801 Vila Real, Portugal, [3] National Institute for Agricultural and Veterinary Research, Agriculture and veterinary medicine, Quinta da Fonte Boa, 2005-048 Santarém, Portugal, [4] AI4Animals, Animal science and veterinary medicine, Professor Egas Moniz Avenue, 1649-028 Lisboa, Portugal

Black soldier fly (Hermetia illucens) larvae have been used in swine nutrition due to their high content of protein, vitamins, minerals, essential amino acids, polyunsaturated fatty acids, and bioactive compounds such as chitin and antimicrobial peptides. Animal production seeks sustainable strategies to improve efficiency, and insects can play an important role in this context. The weaning period is critical for piglets and is often associated with post-weaning diarrhea caused by Escherichia coli. H. illucens larvae have been studied as a feed ingredient due to their nutritional value and antimicrobial potential. This study aimed to evaluate the effects of replacing spray-dried plasma (SDP), a feed ingredient with high protein content, digestibility, and biological value widely used in piglet diets, with defatted BSF meal (DBSFM) in post-weaning piglet diets. The trial included two experimental treatments: 1) Control, with pre-starter and starter diets containing 2.5 and 3.0% SDP, respectively; and 2) DBSFM, with pre-starter and starter diets containing 3.1 and 8.35% DBSFM, respectively. Diets were formulated to be iso-nitrogenous and iso-energetic for each feeding phase. A total of 48 piglets ((LW × LR) × Pi) were randomly allocated to the two treatments and housed in pairs in 24 nursery pens for five weeks. Piglets were weighed weekly, and feed intake was recorded to determine average daily gain (ADG), average daily feed intake (ADFI), and feed conversion ratio (FCR). No significant differences were observed in initial body weight (6.500 vs. 6.302; P=0.4743), final body weight (18.168 vs. 19.028; P=0.3827), ADG (0.331 vs. 0.361; P=0.1895), or FCR (1.803 vs. 1.747; P=0.6446). However, pigs fed the BSF diet showed higher ADFI (0.576 vs. 0.668; P=0.0404). No significant differences were observed between treatments for most hematological and biochemical parameters (P>0.05). However, pigs fed DBSFM showed lower eosinophils (0.375 vs. 0.917; P=0.006), basophils (0.883 vs. 1.442; P=0.029), and absolute eosinophils (0.064 vs. 0.177; P=0.002) compared with pigs fed plasma. In the erythrogram, hemoglobina (10.225 vs. 11.242; P=0.006), hematocrit (34.083 vs. 37.358; P=0.011), and MCH (15.825 vs. 16.492; P=0.044) were lower in the BSF group. In serum biochemistry, only magnesium (2.0 vs. 2.2; P=0.015) and phosphorus (9.2 vs. 10.2; P=0.014) differed between treatments. However, all values remained within the physiological reference ranges. The inclusion of BSF larva meal in place of plasma meal in piglet diets did not cause significant histopathological changes in the heart, lungs, kidneys, liver, or spleen (p > 0.05), suggesting the safety of the ingredient. It is concluded that the inclusion of defatted BSF meal in replacement of plasma meal in post-weaning piglet diets can be carried out without any negative effects. Future trials are suggested to increase sample size and to evaluate other inclusion levels. Keywords: BSF meal, plasma meal, performance, blood parameters, histopathology, piglets

Recovering missing calving events to improve lactation number accuracy in commercial dairy cow datasets

A. Edvardsson Rasmussen[1], I. Ohlsson[2], T. Klingström[2]
[1] Swedish University of Agricultural Sciences, Clinical Sciences, Box 7054, 750 07 Uppsala, Sweden, [2] Swedish University of Agricultural Sciences, Animal Biosciences, Box 7023, 750 07 Uppsala, Sweden

Accurate information on lactation number (parity) is essential in dairy science as both milk yield and lactation curve shape depend strongly on parity. With the increasing availability of data from automated farm systems, large datasets can be used for research, but completeness and recording errors remain a challenge. Farms, even when using the same herd management system, may to various degrees record data about key events such as inseminations, pregnancy checks, calvings, dry off dates and culling decisions. Differences between expected and actual user behaviour may also lead to issues such as a new lactation, as recorded by the herd management system, beginning several days into the actual lactation period. This makes it difficult to accurately filter out dry off periods or dairy cows with high milk yields towards the end of their lactation. The objective of this study was to improve the accuracy of lactation number estimation by identifying and correcting common sources of error in calving registrations and by integrating multiple data sources. Data were obtained from 11 commercial dairy farms participating in the Gigacow infrastructure. The dataset included daily milk yield records, calving registrations and calf birthdates from the DeLaval DelPro herd management system, as well as calving information from the Swedish Official Milk Recording Scheme (SOMRS). Data were retrieved on 6 March 2026. Additional calving events were inferred using calf birthdates linked to their dam through individual identification numbers. The combined dataset was screened for erroneous registrations using biological plausibility checks. Calving intervals shorter than 42 days were considered erroneous, while intervals between 42 and 260 days were retained but flagged as likely abortions. Calving data were merged with milk yield records, and only cows with at least one positive milk yield observation were retained. To ensure temporal consistency, calving events were restricted to periods when milk yield recordings from each respective farm were available in Gigacow. Cow birthdates were used to calculate age at calving and age at first milking. Records with biologically implausible ages were inspected and removed when errors were detected. Data processing and validation were conducted in R using tidy data workflows. Visual inspection of timelines combining birthdates, calving events and milk yield records was used for visual validation of reconstructed lactation histories. Data from the herd management system with and without recovery of calving dates was compared with calving data from SOMRS. Preliminary results show that the initial DelPro dataset contained 75% (2443/3257) of the calving records in the SOMRS dataset. Cleaning of the DelPro dataset where improperly recorded national animal ID numbers were restored recovered an additional 340 calving events and resulted in 85% coverage. Finally, the integrated dataset including inferred calvings contained 87% (2836/3257) of the records in SOMRS. Further improvements are expected by incorporating additional checks based on daily milk yield patterns and age at calving. The proposed approach demonstrates how integrating multiple farm data streams can substantially improve data quality and enable large-scale dairy production research as data becomes available through new data standards and exchange services such as the ICAR Animal Data Exchange standard and the International Dairy Data Exchange Network (iDDEN).

Toward a digital model of dairy cow time budget and related energy expenditure

M. Danglot[1], O. Martin[2], M. Valenchon[2], C. Largouët[3], C. Gaillard[1]
[1] INRAE, UMR 1348 PEGASE, Domaine de la Prise, 16 le Clos, 35590 Saint-Gilles, France, [2] Université Paris-Saclay, INRAE, AgroParisTech, UMR 0791 MoSAR, 22 Place de l'Agronomie, 91120 Palaiseau, France, [3] L'Institut Agro Rennes-Angers, UMR 6074 IRISA, 263 Avenue du Général Leclerc, 35000 Rennes, France

Advances in on-animal and in-barn sensing technologies enable high-resolution behavioural monitoring. However, the utility of these data depends not only on accurate behavioural classification but also on the availability of predictive behavioural models capable of describing the expected temporal organization of activities under normal conditions. Such models can serve as benchmarks for detecting behavioural deviations. To date, very few mathematical models of dairy cattle behaviour have been proposed, and most have been designed with highly specific objectives, typically aiming to predict a single behavioural variable. There is therefore a need for integrative modelling frameworks capable of capturing the full structure of an animal's activity over time.This study proposes a mechanistic and dynamic model that predicts individual dairy cattle time budgets across physiological states, management contexts, and environmental conditions. The model assumes that animals allocate behaviour by minimizing deviations from behavioural needs, defined as daily requirements for feeding, drinking, milking, resting, sleeping, ruminating, social interaction, and environmental engagement. These needs are expressed in terms of target behaviour durations, computed on the basis of daily individual performance variables (milk yield, intake, body weight, etc.) predicted by a lifetime model of dairy cows (InSiliCow), combined with management cues (diet composition, outdoor access, etc.). Stochasticity and adjustable individual parameters (e.g., personality traits) generate inter-individual variability in targeted needs and sensitivity to constraints. Transitions between behavioural states arise from the interaction between internal motivation (unmet needs) and external opportunity (resource availability), while environmental factors (indoor vs. outdoor; parlour vs. robot), temporal cues (feeding schedules, milking, circadian phases), and social constraints (crowding, hierarchy) modulate the decision-making process. The model produces coherent time budgets and additionally estimates individual energy expenditure associated with physical activity.Overall, this framework offers a biologically grounded and flexible tool for exploring how intrinsic animal characteristics, environmental conditions, and management practices shape behavioural dynamics. It also provides a basis for detecting behavioural deviations, competition effects, and welfare-relevant disturbances over time.

Digital Transformation in Animal Assessment: A Mobile Application for Real-Time Data Collection and On-Site Analysis

M. Volk[1], L. Jung[2], D. Hinrichs[1]
[1] University of Kassel, Animal Breeding, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany, [2] University of Veterinary Medicine Hannover, WING, Bischofsholer Damm 15, 30559 Hannover, Germany

Manual data collection using paper forms remains a widespread practice in animal assessment, particularly in field studies, on-farm welfare evaluations, breeding programs, and long-term ecological or behavioral research. However, paper-based workflows require post-hoc transcription into digital systems, which is time-consuming, labor-intensive, and prone to entry errors. This delays analysis and can compromise data quality and reproducibility. Additionally, paper-based documentation may pose biosecurity risks, as forms handled on farms are brought into office environments where pathogens can spread to surfaces, materials, or personnel and subsequently be carried to other farms. To address these systemic challenges, we developed an offline-first mobile application designed for all major farm animal species (cattle, pigs, sheep, goats, poultry), suitable for research, breeding, and on-farm welfare assessments. The application enables fully digital data collection directly in the field. All data is stored locally on the device and is not automatically transmitted, ensuring data security and user control. A key innovation is integrated real-time data analysis. Prior to assessment, the application calculates required sample size, while optional trend monitoring and automated alerts flag outliers or critical values during data collection. Animals can be selected either randomly or automated (e.g., NFC or QR codes). Assessments may be conducted at individual or group level, depending on the study design. Following data entry, results are immediately visualized through interactive graphs, summary statistics and deviation indicators, enabling real-time quality control and detection of anomalies. The system features modular architecture, allowing new assessment criteria, scoring schemes, or image-based guidance to be integrated easily. This supports adaptation to diverse research objectives, genetic evaluations, and welfare assessments. By replacing paper-based workflows, the application reduces transcription effort and minimizes entry-related errors, thereby improving data consistency and reproducibility. It was developed as a non-commercial app with domain experts to ensure practical applicability. The system supports standardized data collection, facilitates data sharing within research teams, and enables tracking of individual animals. Overall, it integrates field assessment and data analysis into a coherent digital workflow for animal science research and on-farm evaluation.

Human classification of pig vocalizations shows limited context-independent emotional structure

C. Winters[1], B. Sleurs[2], W. Gorssen[1]
[1] ETH Zürich, Universitätsstrasse 2, 8092 Zürich, Switzerland, [2] Independent software developer, Marsestraat 72, 3950 Kaulille, Belgium

Pig vocalizations are increasingly used as indicators of affective states in research on emotional capacities. Such interpretations typically assume that animals exposed to similar experimental contexts experience comparable affective states and that vocalizations can be assigned to discrete emotional categories—presupposing biologically fixed emotional signatures inferable from acoustic structure alone. However, advances in affective neuroscience emphasize degeneracy, whereby similar behavioral outputs may arise from different internal processes, suggesting emotional categories may reflect observer-dependent interpretations rather than direct access to internal states. Previous studies have relied largely on forced- or multiple-choice paradigms, which may inflate classification accuracy. Few studies have examined how humans spontaneously group pig vocalizations without contextual cues. This study examined human classification of pig vocalizations using a free-sorting paradigm. Vocalizations were obtained from the Soundwel database and filtered using objective acoustic quality criteria (SNR ≥ 6 dB, duration ≥ 0.10 s, loudness ≥ −30 LUFS), yielding 3,144 calls from 18 experimentally defined contexts. In February 2026, 216 participants freely grouped 40 sounds (two per context plus controls) into self-defined categories online. Similarity matrices based on co-classification patterns were constructed at the context level, hierarchical clustering applied using hclust in R, and semantic analysis performed via WordNet through Python's NLTK interface within R. Within-context consistency was moderate (mean = 48.0%, SD = 16.9%) and varied substantially across contexts. Highest consistency was observed for negative conditioning (70.4%), positive conditioning (69.0%), and castration (61.1%); lowest for crushing (27.3%), novel object test (30.6%), and short reunion (30.6%). Hierarchical clustering revealed three broad clusters corresponding to handling-related (e.g., castration, restraint), social (e.g., nursing, huddling), and experimental or environmental contexts (e.g., enrichment, barren), with within-cluster similarity of 0.52–0.89 and between-cluster similarity of 0.10–0.71. The most distinct cluster contained vocalizations from castration, restraint, fighting, and crushing in piglets. Semantic analysis showed these contexts received the highest proportion of "feeling"-related labels (27–35%), predominantly negative in valence. Sounds from positive and lower-intensity negative contexts showed considerably more overlap, with mixed positive and negative semantic labels. Clustering patterns were highly similar across expertise levels ($r = 0.92–0.94$). Higher-expertise participants replayed sounds fewer times before classifying (−1.3 replays, $p < 0.0001$), but expertise did not improve classification consistency. Overall, humans showed only moderate ability to recover context-related structure without contextual information. Substantial overlap across contexts and limited influence of expertise suggest spontaneous perception relies on coarse acoustic heuristics rather than stable, context-specific vocal signatures, supporting a cautious interpretation of pig vocalizations as direct indicators of discrete emotional states.

Low cost IoT system for monitoring environmental conditions and behavior in pig production

J. A. Osorio Saraz[1], V. Gonzalez Cadavid[4], F. A. Obando Vega[2], E. Herrera Pasos[4], A. M. Diaz Lopera[3]
[1] Universidad Nacional de Colombia - Sede Medellín, Departamento de Ingeniería Agrícola y Alimentos, Carrerar 65#59A, 0500 Medellín, Colombia, [2] Institución Universitaria Digital de Antioquia, Engineering Faculty, Carrera 55#42, 0500 Medellín, Colombia, [3] Politecnico Colombiano Jaime Isaza Cadavid, Engineering Faculty, Carrera 48#7, 0500 Medellín, Colombia, [4] Universidad Nacional de Colombia Sede Medellín, Departamento de Producción Animal, Carrera 65#59A, 0500 Medellín, Colombia

Livestock farming production have been using modern technologies and techniques in order to impact the sustainability of the animals production. Conventional livestock production systems, as well some research in different livestock areas have been using equipment and tools to monitoring the environment and Pig behavior, that are usually expensive, reducing the opportunities to be acquire either for small and medium producers and research applications in livestock production. Based on this context, a low-cost open-source IoT tool for monitoring pig behavior and environmental conditions in facilities production was developed. The system was validated and tested in a maternity pig farm, where the developed sensor network has provided reliable information as temperature, humidity, light intensity, temperature of the sows and piglets, black globe temperature, sound, CH4 concentration and records normal or abnormal animal behavior, and it could be used to support decision-making and technological processes in livestock production, as well in various research projects. Further adjustments specific variables will be implemented the second phase of this research.

Added value of multi-sensor behavioural monitoring in infectious disease trials: a case study with pigs challenged with African Swine Fever Virus

H. P. Doekes[1,2], B. Han[1], N. Oreshkova[1], R. De Jong[1]
[1] Wagenigen University & Research, Wageningen Bioveterinary Research, Houtribweg 39, 8221 RA Lelystad, Netherlands, [2] Wageningen University & Research, Aniaml Breeding and Genomics, Droevendaalsesteeg 1, 6708 PB Wageningen, Netherlands

Animal experiments, such as vaccine efficacy trials, can benefit from sensor-based behavioural monitoring. Compared to traditional (bi-)daily clinical observations, sensors provide 24/7 behavioural data that may allow for earlier detection of anomalies and for a more detailed assessment of differences between animals. Here, we explored the added value of sensor-based monitoring of activity and feeding behaviour in a vaccine efficacy trial with three groups of pigs challenged with African Swine Fever Virus. Four weeks before the challenge, group 1 (n = 6) had received a candidate vaccine orally, group 2 (n = 6) had received the same vaccine intramuscularly, and group 3 (n = 4) was mock-vaccinated. From one week before the challenge onwards, we used our recently developed tool RAMSMART (https://git.wur.nl/nlas-asg/ramsmart) to monitor individual animal activity in all three groups. RAMSMART uses a lightweight accelerometer that continuously computes the Vectorial Dynamic Body Acceleration (VeDBA) through edge computing and broadcasts this VeDBA once per minute through Bluetooth low energy to a nearby receiving device. In group 3, we also applied a RFID system in the feeder (with 4-7 reads per second) to detect feeding visits. A feeding visit was defined as a series of detections lasting for at least 3 seconds and at most 5 minutes, with a maximum gap in between subsequent detections of 10 seconds. On day 3 after the challenge, VeDBA levels significantly dropped in orally vaccinated group 1 and the mock-vaccinated group 3, whereas the intramuscularly vaccinated group remained on its normal activity level. This was in line with the onset of fever in the groups, and RAMSMART detected these anomalies one day earlier than the rise in (bi-)daily clinical activity scores. On day 5, the mean VeDBA in groups 1 and 3 had reduced to <30% of what it used to be before challenge. Similarly, the RFID-based number of feeding events and feeding duration dropped in group 3 from day 3 onwards, whereas clinical appetite scores only increased on day 4 after the challenge. In the week before the challenge, each pig of group 3 visited the feeder approximately 75 times a day (with total duration ~60 minutes), whereas on day 4 after the challenge this reduced to less than 10 times a day (in total < 5 minutes). Overall, we demonstrate the added value of sensor-based monitoring in clinical (vaccine) trials and recommend wider implementation of such technologies to improve the quality of experimental results and refine animal trials.

Application of Multimodal IMU Metrics to the Behavioral Assessment of Pigs

D. Foy[1,2], T. Smith[1], J. Reynolds[1], T. Parsons[2,3]
[1] AgriGates, Philadelphia, 19146 Philadelphia, United States, [2] DAT-AI-LAB, 505 Byrd Rd, 19348 Kenneth Square, United States, [3] University of Pennsylvania School of Veterinary Medicine, Swine Teaching and Research Center, 382 West Street Road, 19348 Kennett Square, United States

Multimodal data streams are becoming increasingly prevalent in animal behavior research, offering new opportunities to capture behavioral states and events with greater temporal resolution and contextual depth. Common data stream sources include video cameras, audio recorders, global positioning system (GPS) trackers, and wearable inertial Measurement Units (IMUs). The latter incorporates accelerometers, gyroscopes, and magnetometers to provide 9-axis high-frequency primary sensor outputs for interpretation, and, when synchronized with video and/or audio recordings, allows for fine-scale temporal alignment between observed behavior and underlying movement dynamics. Several interesting metrics can be derived directly from the individual IMU component outputs. The accelerometer yields a measure of activity from the total three-axis acceleration. The gyroscope offers angular velocity and acceleration, and the magnetometer reports orientation across three axes. However, the ability to define multimodal metrics via calculations across outputs from different sensors can provide novel insights into animal behavior. For example, combining the accelerometer and magnetometer outputs enables tracking an animal's path via dead reckoning. Calculating across the accelerometer and gyroscope data allows for the determination of an animal's true movement independent of posture via gravity-compensated linear acceleration. While there are a variety of other multimodal metrics that can arise from sensor fusion (Linear acceleration, Gravity vector estimate, Orientation estimates [Pitch / Roll / Yaw], etc.),a convenient platform for applying these novel metrics to animal behavior has not been available, particularly for easily calculating and visualizing them in an interpretable context. Here, we present a workflow that starts with parsed raw IMU wearable outputs and ends with the simultaneous, time-aligned visualization of behaving sows equipped with animal-borne IMUs, and the multimodal metrics calculated from those IMUs' outputs. A single interactive environment enables the calculation and visualization of user-defined metrics from the IMU's accelerometer, gyroscope, and magnetometer outputs. A dedicated annotation software facilitates the labelling of multimodal data for behavioral states and events from concurrently coded IMU data and video recordings. These multimodal annotations are then visualized within a custom analytical interface developed in Power Query for relational structure and Power BI, allowing users to readily explore synchronized behavioral labels alongside calculated IMU metrics. By linking multimodal IMU orientation and amplitude metrics with annotated behavioral patterns, this approach provides deeper insight into behavioral transitions, a digital ethogram with states and events, and temporal structure that are often lost in traditional ethograms. Such multimodal visualization and fusion frameworks support more robust behavioral assessment and facilitate the development of biologically grounded machine-learning models.

Development of an Automated Posture Prediction System for Sows Using Artificial Intelligence

T. Cochou[1], N. Barry[1], J. F. Bompa[1], W. Hébrard[3], S. Ferchaud[4], G. Delosières[1], M. Aletru[1], L. Canario[1], M. Bonneau[2]
[1] INRAE, 24 Chemin de Borde Rouge, 31320 Castanet-Tolosan, France, [2] INRAE, Domaine de Duclos, 97170 Petit-Bourg, Guadeloupe, [3] INRAE, Domaine du Magneraud, 17700 Surgères, France, [4] INRAE, La Gouvanière, 86480 Rouillé, France

Monitoring animal behavior is needed for detecting major physiological events in livestock farming and for assessing welfare. The objective was to develop an automated posture prediction device for loosed-housed sows using a Convolutional Neural Network, the YOLO object detection. The system, consisting of a minicomputer included in a waterproof central unit and connected to one to three cameras positioned above and behind the sow's pen to enable individual observation, was developed in our workshop and then tested under farm condition in INRAE experimental farm. The artificial intelligence model was trained on a database of 10,483 images including two different farms and conditions whether animals were housed on slatted floor or on straw and dozens of Large White sows, taken from any moment of the day, to recognise eight distinct sow postures, as well as the location of her head and the location of each piglet. Dedicated softwares were designed for system configuration, real-time data processing, and result visualisation. It can be controlled without internet using a digital device that can connect to a wireless connection. The processing and visualisation softwares are also available for use at the office with additional features. Initial results from on-farm testing show a significant correlation between postural activity and the approach of farrowing. Notably, a marked increase in the frequency of posture changes and the increased use of specific postural sequences were observed in the hours preceding the event. These behavioral variations, automatically quantified by the system for each sow (each camera), represent promising early indicators for predicting farrowing and identifying potential health issues. This computer vision system, encompassing both hardware and software components, demonstrates the potential of embedded artificial intelligence techniques for developing decision-support tools in precision livestock farming. Its flexible architecture also allows for future applications in other species, simply by retraining the model on the target species' behavioral data. It paves the way for non-invasive, continuous monitoring, ultimately improving both animal health and welfare, and farm management efficiency.

Automated computer vision analysis of pig appeasing pheromone effects on social behaviour and welfare in group-housed sows

N. Ipek[1], J. Verwaeren[1], B. De Baets[1], F. Tuyttens[2,3]
[1] Ghent University, Department of Data Analysis and Mathematical Modelling, Coupure Links 653, 9000 Gent, Belgium, [2] ILVO, Animal Sciences Unit, Burg. van Gansberghelaan 119, 9090 Merelbeke-Melle, Belgium, [3] Ghent University, Department of Veterinary and Biosciences, Heidestraat 19, 9820 Merelbeke-Melle, Belgium

In the EU, the reproductive cycle of sows commonly includes prolonged periods of individual housing during the farrowing and insemination phase, followed by the mandatory group housing during the gestation phase. The regrouping of previously familiar and partly unfamiliar sows at the start of gestation triggers agonistic interactions for (re-)establishing a social hierarchy. This period of social unrest is associated with stress and a high incidence of lesions and lameness, posing welfare and productivity challenges. The aim of this study was to investigate whether social unrest and its negative consequences could be alleviated by the application of a Pig Appeasing Pheromone (PAP) during the first week of the gestation period. In a double-blind experiment, 8 groups of sows (16–20 per group) were randomly allocated to a PAP (9 diffuser blocks containing 2% SecurePig® distributed across the pen from 3d before until 7d after mixing) or placebo treatment (identical placement of diffuser blocks lacking the active PAP component) at the start of the gestation period. Skin lesions obtained after mixing were scored on d2, d7, d9 and d17. Four cameras per pen were used to video-record the uniquely marked sows continuously from 8-20h for 17d after mixing. An in-housed developed and validated automated computer-vision-based system was used to enable high-resolution, continuous tracking and analysis of individual and dyadic behaviour. Zero-shot-learning-based segmentation, identification, and tracking enabled quantification of movement and agonistic interactions. Our AniDomNet tool was fitted separately to sequential fleeing and displacement interactions to infer social dominance matrices and directed acyclic graphs. Effects of treatment were tested using linear mixed models. PAP was associated with reduced overall movement ($p = 0.002$), fighting ($p = 0.011$), fleeing ($p < 0.001$), displacements ($p < 0.001$), and skin lesion scores ($p = 0.046$). The largest reduction occurred between d2 and d7 post-grouping, following the initial peak in agonistic behaviour immediately after mixing. These effects were sustained following PAP diffuser removal at d7 without signs of a rebound effect. The AniDomNet hierarchies based on fleeing vs displacements showed 65% agreement, and indicated a broadly linear dominance structure with some unsettled dyads. The effects of PAP on hierarchy structure seemed marginal: PAP groups showed slightly less linear hierarchies (using Landau h) and less settlement at lower ranks. High-ranked animals had more strongly preferred resting places, were on average further away from the feeding station, moved less (especially in control groups), were closer to each other during resting, and occupied areas less equally as compared to lower-ranked sows. This study demonstrates that PAP administration can reduce social stress during early gestation grouping, and that integrating zero-shot learning with continuous tracking provides a scalable, observer-independent approach for advancing ethological research in group-housed farm animals.

Camera-based computer vision monitoring of pig behaviour under heat stress

N. Hlel[1], D. A. Mendez[1], X. Díaz De Otálora[1], F. Estellés[1], S. Calvet[1], D. Liu[2], T. Norton[2]
[1] Institute of Animal Science and Technology (ICTA), Universitat Politècnica de València, Camino de Vera, 46022 Valencia, Spain, [2] Division M3-BIORES: Measure, Model & Manage Bioresponses, Catholic University of Leuven, Department of Biosystems, Kasteelpark Arenberg 30, 3001 Heverlee, Leuven, Belgium

Animals' exposure to high temperatures increases the risk of heat stress. Precision livestock farming (PLF) tools, such as camera-based computer vision, enable continuous, non-invasive monitoring of animal behaviour and can help detect heat stress at an early stage. This study aimed to assess behavioural responses of fattening pigs to heat stress using video-based analysis. The study was conducted at the CITA-IVA facilities (Segorbe, Spain) from 19 June to 18 July under commercial conditions. Here eight cameras were installed in top view in eight pens, each with a different floor type: four with fully slatted floors and four with partially solid floors with stirring fans. Each pen housed eight pigs and was continuously monitored. Temperature and humidity were continuously recorded using Dräger sensors, and the temperature–humidity index (THI) was calculated to quantify heat load. A total of 500 labelled images from our recordings were used to train the model for our experimental setup. Videos were analysed at 1 frame per second using the M3PIG pipeline (https://gitlab.kuleuven.be/m3-biores/public/m3pig). Rotated bounding boxes, ten keypoint positions (from snout to tail base), and posture (lying on the belly, right and left sides, sitting, standing) were also extracted. Space use (solid vs slatted floor), feeding and drinking behaviour were derived from annotated regions of interest, allowing the identification of animal position relative to floor type, feeders, and drinkers. Preliminary results showed that pigs spent most of their time lying (83.1%), with standing and sitting accounting for 15.2% and 1.7%, respectively, reflecting pigs' reduced activity in hot conditions as a thermoregulatory response. Lying time increased ($r = 0.2$), standing decreased ($r = -0.2$), and feeding time decreased ($r = -0.3$) with increasing THI. These behavioural changes may contribute to differences in emission dynamics reported in partially solid flooring systems. Increasing THI was also associated with greater use of the solid floor ($r = 0.32$) and less use of the slatted floor (-0.32), indicating a shift toward cooler areas under heat stress. These behavioural changes demonstrate that posture, floor use and feeding are sensitive indicators for automated detection of heat stress in pigs, supporting their integration into PLF tools for early management decision-making.

Zero-shot computer vision-based analysis of social behaviour among group-housed sows

N. Ipek[1], J. Verwaeren[1], B. De Baets[1], F. Tuyttens[2,3]
[1] Ghent University, Department of Data Analysis and Mathematical Modelling, Coupure Links 653, 9000 Gent, Belgium, [2] ILVO, Animal Sciences Unit, Burg. van Gansberghelaan 119, 9090 Merelbeke-Melle, Belgium, [3] Ghent University, Department of Veterinary and Biosciences, Heidestraat 19, 9820 Merelbeke-Melle, Belgium

In group-housed sows, dominance hierarchies are established through frequent, often brief agonistic interactions. Quantifying reliable dominance dynamics requires high-resolution, individual-level monitoring of behaviour. Traditional behaviour scoring is often limited by short observation periods and constrained by observer subjectivity. Existing automated approaches often depend on human annotations for supervised models and require pen-specific tuning, limiting transferability across environments and experiments. Here, we present the development and validation of a scalable computer vision pipeline for long-term automated monitoring of group-housed sows using zero-shot learning, enabling quantification from movement patterns to dominance hierarchies with reduced reliance on pixel-level annotations. Four ceiling-mounted cameras per pen captured continuous video of 16–20 uniquely marked sows per group over a 17-day observation period. These video recordings were analysed at the frame level using a zero-shot segmentation pipeline that combined DINO-based self-supervised features, a U-Net refinement step, and SAMv2 mask proposals. Individual (re-)identification was performed using a supervised MaxViT network trained on unique marking patterns, where confidence-weighted predictions were aggregated within tracks to reduce identity switches. Multi-camera detections were aligned on a common timeline and filtered using mask geometry to mitigate peripheral lens distortion. Tracklets were formed using spatiotemporal continuity and automatically linked across pen sections using pen geometry. Occlusions and short recording gaps were handled using conservative track termination and hourly stitching, without interpolating missing positions. A grid-based post-processing step was applied to further reduce jitter and improve the stability of spatial position estimates for individual sows. Three agonistic interaction types (fighting, fleeing, and displacement) were modelled using a rule-based classifier based on trajectories and dyadic configurations. These interactions were used to infer group-level dominance dynamics with AniDomNet, a probabilistic dominance inference model that estimates a dominance matrix from sequential dyadic interactions and constructs a directed acyclic graph to derive rankings. Dominance hierarchies were inferred separately for fleeing and displacement behaviours. The track precision when validated against manual annotations showed high robustness, reaching 96.6%. The (re-)identification network achieved a validation accuracy of 98.6%. Detection precision for agonistic interactions was 0.82 for fighting, 0.73 for fleeing, and 0.77 for displacement. Overall, integrating zero-shot learning with multi-camera tracking enabled scalable, observer-independent behavioural quantification in group-housed farm animals, with improved transferability to new pens.

Moo4feed R package: Decoding individual animal narratives through precision livestock monitoring data

K. Sheng[2], B. Foris[1,2], D. Weary[2], M. Von Keyserlingk[2]
[1] University of Veterinary Medicine, Animal Welfare Science Unit, Veterinärpl. 1, 1210 Vienna, Austria, [2] Animal Welfare Program, The University of British Columbia, Faculty of Land and Food Systems, 2357 Main Mall, V6T 1Z6 Vancouver, Canada

Precision Livestock Farming (PLF) technologies enable continuous, automated monitoring of individual animals, yet most data analysis still relies on group-level comparisons that omit meaningful individual differences. There is a growing acceptance that animals housed in identical environments exhibit different behaviors even when healthy, thus for accurate and timely detection of health or welfare challenges it is important to track within animal changes, rather than applying herd-level thresholds and a 'one size fits all' treatment. The aim of this study was to extract existing PLF data streams to identify novel behavioral variables and characterize individual-level behavioral consistency in dairy cows. Data were collected from 159 lactating Holstein dairy cows at the UBC Dairy Education and Research Centre over 10 months. We applied strict data cleaning and filtering to exclude periods of illness, lameness (based on two consecutive non-lame weekly scores), estrus, technical outage, and regrouping events, which resulted in a total of 73 cows across 47 days within 3 stable periods. We identified 21 behavioral variables derived from electronic feed bin and water trough (Insentec, NL) data. Beyond conventional intake metrics (e.g., feed and water intake, duration, meal frequency), we extracted variables capturing exploratory behavior (e.g., non-nutritive visits), social dynamics (e.g., rate of initiating or receiving agonistic displacements per meal), and indicators of feed access quality (e.g., proportion of meal time spent actively eating versus waiting, proportion of fresh feed remaining upon arrival). Bayesian mixed-effects models were used to quantify repeatability (CVi; between-individual variation in average behavioral expression) and predictability (rIIV; residual intra-individual variance). Non-nutritive visits per meal (CVi = 0.676, rIIV = 2.330), proportion of actor displacements per meal (CVi = 0.638, rIIV = 2.065), total non-nutritive visits per day (CVi = 0.622, rIIV = 2.170), proportion of reactor displacements per meal (CVi = 0.469, rIIV = 2.024), median water visit duration (CVi = 0.412, rIIV = 2.637), and median visits per meal (CVi = 0.377, rIIV = 1.925) all exhibited high between-individual variation alongside low residual intra-individual variance, indicating these behaviors stay relatively consistent within individuals but differ between individuals. To support full reproducibility, we developed the moo4feed R package (www.skysheng.io/moo4feed/), a well-validated (96% test coverage) data science workflow with detailed tutorials for extracting these behavioral variables from raw PLF data, enabling future work to verify and build upon our methods. These findings demonstrate that in the case of automatic feeding and drinking systems there is tremendous potential to capture additional behavioral information beyond what is typically reported. Promoting individual-based behavioral profiling in dairy cattle, enabled through PLF technologies, is an important first step to developing new ways of improving early disease detection, affective state assessment, and personality characterization.

Influence of incomplete milking on the oxidative stress status in dairy cows during peak to mid lactation

K. M. Flüchten[1], P. M. Von Trotha[1], R. Joest[1], B. Heitkönig[1], C. Heinemann[1], U. Müller[1]
[1] University of Bonn, Institute of Animal Science, Katzenburgweg 7-9, 53115 Bonn, Germany

High milk production may represent a metabolic challenge in dairy cows. Previous studies demonstrated that automated short-term incomplete milking (IM) has the potential to alleviate metabolic load without impairing udder health or animal welfare indicators. The objective of this study was to investigate the effects of IM on oxidative stress status in multiparous Holstein cows during peak to mid lactation. As digital innovation for IM, a specialized software that precisely controlled milk withdrawal was implemented. A total of 46 multiparous Holstein cows housed under standardised conditions were included in a controlled experimental design. Twenty-three cows were assigned to the IM group, in which IM was implemented according to the individual milk yield using a software module that enabled automated early cluster removal. During the first phase of IM, milk withdrawal was gradually reduced by 9%/ day for 5.5 days to achieve an approximate 40% reduction. In the second phase of IM, milk withdrawal was maintained at the approximate 40% reduction in a constant manner for an additional 5.5 days. Two weeks before and after the IM period, IM cows were milked equally to control cows (CON group, n = 23), which underwent milk flow-based cluster removal at <0.3 kg/ min). Blood samples were collected weekly from the Vena Jugularis and plasma were analysed photometrically for indicators of oxidative stress, including derivates of reactive oxygen metabolites (dROM), advanced oxidation protein products (AOPP), thiobarbituric acid reactive substances (TBARS) and ferric reducing ability of plasma (FRAP). Additionally, the oxidative stress index (Osi = dROM / FRAP * 100) was calculated for each cow. Data were analysed using a linear mixed – model including treatment, time, treatment × time interaction, number of lactation and milk yield groups (> 40 kg vs. < 40 kg ECM / d) as fixed effects, and cow and days in milk at the beginning of the treatment as random effects. Alpha error correction for multiple comparisons was applied using the Bonferroni method Statistical significance was set at $P \leq 0.05$ and values are shown as mean ± SE. Oxidative stress indicators were comparable between groups and remained stable over time: (a) dROM: IM group 99.2 ± 3.6 µg H2O2 equivalent/mL, CON group 103.6 ± 3.6 µg H2O2 equivalent/mL; (b) AOPP: IM group 1.04 ± 0.09 µmol/g Protein, CON group 1.07 ± 0.02 µmol/g Protein; (c) TBARS: IM group 311 ± 5.3 nM, CON group 289.3 ± 3.6 nM; (d) FRAP: IM group 251.7 ± 2.4 µM Fe^{2+}/L, CON group 258.9 ± 2.6 µM Fe^{2+}/L; (e) Osi: IM group 40.01 ± 1.5, CON group 40.7 ± 1.3. No significant effects of IM were detected for any oxidative stress indicator ($P > 0.05$), neither between treatments, nor across weeks within a treatment group. In conclusion, automated short-term IM did not affect oxidative stress status in multiparous Holstein cows during peak to mid lactation, suggesting that the previously observed reduced metabolic load induced by IM does not translate into altered oxidative cell stress.

Automatic detection of cattle vocalizations based on spectrogram correlation, eigensounds, and deep learning embedding approaches

D. Gavojdian[1,2], L. S. Dragne[2], M. Mincu-Iorga[1,2], A. C. Olteanu[2]
[1] Research and Development Institute for Bovine, Sos. Bucuresti - Ploiesti, km 21, 077015 Balotesti, Romania,
[2] National University of Science and Technology Politehnica, Splaiul Independentei 313, 060042 Bucharest, Romania

The use of vocal indicators represents a unique and non-invasive means of assessing farmed animals' behaviour and welfare. The current study aimed to develop and evaluate the performance for a number of three detection approaches in order to automatically identify cattle vocalizations from audio recordings, as follows: i) spectrogram correlation using Praat and Parselmouth, ii) eigensounds analysis based on Principal Component Analysis, and iii) deep learning embeddings using the pre-trained YAMNet model. For this reason, we used curated audio-recordings from 20 Romanian Holstein lactating multiparous dairy cows, each monitored individually in a tied stanchion barn, following visual isolation of 1-hour post-morning milking. To assess and compare performance of the detection approaches, we evaluated the median precision and recall across all recordings. The spectrogram-correlation achieved a modest performance, with a precision of 0.53 and a recall of 0.28, reflecting most likely sensitivity to background environmental noises. The eigensounds approach had a moderate precision of 0.57 and a recall of 0.72, indicating thus a stronger sensitivity to factual vocalizations. In contrast, the YAMNet based embedding method offered the highest precision, of 0.88, all while maintaining a recall of 0.58. Current findings suggest that the three approaches can play distinct and synergistic roles in the development of future acoustic monitoring systems. This work targeted the automated detection and segmentation of individual vocalizations emitted by cattle, under farming conditions. Manual annotation of cattle vocalizations, although accurate when trained technicians are being used, requires intensive and time-consuming labour, while being difficult to keep consistent when hours long audio files are concerned. Therefore, throughout automatization of this step, two potential benefits arise, firstly it enables to work with significantly larger audio-sets, and secondly, makes real-time on-farm surveillance plausible, with no or little human-assistance needed during routine operations.

Gender-Related Differences in Growth Performance, Carcass Traits and Blood Parameters of Finishing Pigs

J. Paié-Ribeiro[1], D. Outor-Monteiro[1,2], V. Pinheiro[1,2]
[1] University of Trás-os-Montes ald Alto Douro, Veterinary and Animal Research Centre (CECAV), Quinta de Prados, 5000-801 Vila Real, Portugal, [2] University of Trás-os-Montes ald Alto Douro, AL4Animals, Quinta de Prados, 5000-801 Vila Real, Portugal

Gender remains a key factor influencing growth performance, carcass traits and metabolic profile in pigs, particularly during the finishing phase. Within this framework, the present study aimed to assess sex-related differences in productive performance, backfat thickness and blood parameters in commercial pigs during the last four weeks of finishing. The study was conducted at UTAD Experimental Pig Farm facilities in Vila Real. Twenty-four Landrace × Large White pigs (12 males and 12 females) with initial body weight of 81.2 kg for females and 82.9 kg for males were allocated in individual pens and fed balanced diets under ad libitum conditions. Feed intake and live weight gain were monitored weekly. At the end of the trial, subcutaneous fat was evaluated at the rib level using a UTR device. Animals were sent to an official slaughterhouse, and at the time of slaughter, individual blood samples were collected and analysed to determine complete blood count and serum biochemistry. Data were analysed using ANOVA with gender as the main factor, and Tukey test was used for multiple comparisons of means. Statistical analyses were performed using JMP Pro 17. At the end of the finishing period, males exhibited significantly higher final body weight compared to females (110.0 vs. 103.7 kg; $p = 0.007$). Average daily gain followed the same trend, being greater in males (113.5 vs. 103.7 g/day; $p = 0.006$). No significant differences were observed in average daily feed intake ($p > 0.05$), while feed conversion ratio was markedly better in males (3.30 vs. 3.84; $p = 0.0001$), indicating superior growth efficiency. Backfat thickness tended to be higher in females (11.7 vs. 10.4 mm; $p = 0.096$). Serum biochemical analysis revealed no significant sex effects on GGT, ALT, AST, alkaline phosphatase or total bilirubin ($p > 0.05$). However, females presented higher total cholesterol (75.8 vs. 64.7 mg/dL; $p = 0.046$) and triglyceride concentrations (49.1 vs. 40.5 mg/dL; $p = 0.024$). Regarding haematological parameters, haematocrit percentage (46.05 vs. 42.53%; $p = 0.0061$) and haemoglobin concentration (14.23 vs. 13.03 g/dL; $p = 0.0145$) were significantly higher in females, while other parameters (erythrocytes, leukocytes, platelets, leukocyte formula, and mean corpuscular haemoglobin concentration) were not affected by sex. Overall, these findings confirm that biological sex significantly modulates growth efficiency and lipid-related metabolic traits in finishing pigs. Males demonstrated superior productive performance, whereas females exhibited a more pronounced lipid and erythroid profile. These differences should be considered when interpreting physiological responses in finishing pigs and in the optimisation of finishing management strategies. Keywords: Finishing pigs, sex differences, blood parameters Acknowledgments: This work was supported by the projects UID/00772/2025, DOI https://doi.org/10.54499/UID/00772/2025 funded by the Portuguese Foundation for Science and Technology (FCT).

Automated Monitoring of Rabbit Activity Using Computer Vision: A Comparison of Gaussian, SAM3, and YOLO Algorithms

T. Monreal Fernandez[2], B. Fajardo Viloria[1], E. Gil Vidal[1], F. Marco[1], S. Calvet[1], D. A. Méndez Reyes[1]
[1] Universitat Politècnica de València, Instituto de Ciencia y Tecnología Animal, Ca, Camí de Vera s/n, 46022 Valencia, Spain, [2] Universitat Politècnica de València, Instituto Universitario Valenciano de Investigación en Inteligencia Artificial, Camí de Vera s/n, 46022 Valencia, Spain

The management of commercial rabbit farming currently faces significant operational challenges, prominently the difficulty of detecting and analyzing rabbit activity in real-time. In this context the continuous monitoring of rabbit activity is time consuming, but key for detecting specific movement patterns that serve as early indicators of the animal's welfare and physiological state, such as identifying productive periods or detecting early signs of stress before they impact animal health. To address this, this study evaluates and implements multiple computer vision methodologies to quantify rabbit movement under standard husbandry conditions. Data acquisition was conducted at the experimental rabbit farm of the Universitat Politècnica de València (Eastern Spain). Video data was captured continuously over one month using top-view cameras. The experimental setup consisted of 8 individual cages (58×40 cm), housing one rabbit each, and two collective group-housing pen (176×176 cm) with 45 rabbits to monitor free interaction. Initially, a traditional, lightweight approach was tested using a Gaussian Mixture Modeling (GMM)-based background subtraction function (BackgroundSubstractorMOG2) via OpenCV. While effective for basic overall motion detection, more advanced segmentation was required in order to identify additional activities. Consequently, the heavy-computational Segment Anything Model 3 (SAM3) was implemented. Relying only on a prompt for rabbit identification, SAM3 provided highly reliable segmentation and tracking; however, its high computational cost made processing long videos difficult and restricted real-time, on-farm application. To overcome these processing demands, an efficient pipeline was developed. SAM3 was utilized strictly as an automatic annotation tool to precisely segment and label rabbits in their housing conditions with human verification. To enrich the model's predictive capacity, frames with high uniqueness were preselected for this auto-generated dataset, which was then used to train a computationally lighter object detection model (YOLO26). Preliminary results indicate that while the GMM approach effectively measures general movement, SAM3 offers the highest potential for segmentation at the cost of deployability. On the other hand, YOLO26 achieved reliable detection and faster inference speeds. It also demonstrated the capability to classify specific activities, such as visiting feeders or drinkers, and measure overall speed and movement in the collective pens. Ultimately, this methodology demonstrates that distilling high-load foundational models like SAM3 into efficient models like YOLO26 provides a viable, scalable solution for real-time activity measurement in precision livestock farming.

Can piglets self-regulate their intake when offered two contrasting diets differing in protein and energy?

M. Traineau[1], J. Danel[2], M. Vilarino[1]
[1] ARVALIS, 2 pouline, 41100 Villerable, France, [2] ARVALIS, Rue de L'Etang, Gran Castel, 56800 Ploërmel, France

Precision feeding has emerged as a promising nutritional strategy in modern swine production, aiming to closely align nutrient supply with the individual requirements of animals across physiological stages. In piglets, whose nutritional needs are particularly dynamic during the post-weaning period, precision feeding helps limit the oversupply of costly nutrients such as amino acids and phosphorus, thereby reducing nitrogen excretion and the environmental footprint of pig production. Previous studies have shown that precision feeding systems based on real-time sensors and automated feeding technologies can maintain or even improve growth performance—including average daily gain (ADG), feed conversion ratio (FCR), while reducing feed costs by up to 10–15%. Beyond imposed dietary regimens, pigs exhibit active feed preferences linked to macronutrient composition, consistent with the concept of nutrient-specific appetites. When offered dietary choices, piglets are able to self-select macronutrient intakes that approximate a regulated intake target, prioritizing protein under limiting conditions or favouring energy-dense diets when energy demands are high. The present study investigated the dietary choices of group-housed piglets given simultaneous access to diets differing in net energy (NE) and crude protein (CP) content, with the objective of characterizing macronutrient selection patterns and assessing the nutritional and performance consequences of voluntary feed choice. To this end, 80 male and female piglets equipped with RFID tags were housed in four group pens and provided access to two automatic feeders capable of recording feed intake, number of visits to the feeder, and time spent at the feeder. One NE (kcal/kg) / CP (%) diet pair was evaluated under free-choice conditions in each pen, with the individual animal considered as the experimental unit. A control treatment consisted of the same diet offered in both feeders (2260/18.5), while three levels of nutritional contrast were tested under free-choice conditions: High (2400/13.5 and 2120/23.5), Moderate (2344/15.5 and 2176/21.5), and Low (2316/16.5 and 2204/20.5). If piglets consumed both diets in a 50:50 ratio, the resulting intake would be nutritionally equivalent to the control diet. Over the experimental period, piglets receiving the control diet consumed similar amounts from both feeders. In contrast, in pens offering contrasted dietary choices, animals showed a clear preference for energy-rich diets from the first week until the end of the experiment. After three weeks, piglets consumed 78% of the 2400/13.5 diet in the high-contrast pair, 70% of the 2344/15.5 diet in the moderate-contrast pair, and 60% of the 2316/16.5 diet in the low-contrast pair. Time spent at the feeder reflected feed intake patterns, whereas the number of feeder visits did not differ between diets within any pair throughout the trial. Despite these pronounced preferences, no differences in final body weight were observed after three weeks of dietary choice, although piglets offered the low-contrast diets were numerically heavier by approximately 1.6 kg compared with those in the other pens. Similarly, no differences—either statistical or numerical (<1.5%)—were detected in feed conversion ratio. In conclusion, when faced with strong dietary contrasts, piglets preferentially overconsume energy-rich diets relative to protein-rich diets, demonstrating a clear preference for high-energy feeds. Importantly, these dietary imbalances did not impair growth performance compared with piglets consuming a conventional complete diet.

Effects of incomplete milking during summer on metabolic and oxidative status in peak-lactation dairy cows: a pilot study

R. Joest[1], M. Ghaffari[2], T. Hartinger[1], U. Müller[1]
[1] University of Bonn, Institute of Animal Science, Katzenburgweg 7, 53115 Bonn, Germany, [2] Research Institute for Farm Animal Biology, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany

Heat stress places a significant metabolic burden on high-producing dairy cows, as the energy required for milk synthesis increases endogenous heat production and limits thermoregulatory capacity under elevated ambient temperatures. Temporarily reducing mammary nutrient demand may therefore serve as a physiological strategy to lessen metabolic strain during thermal challenges. As a digital innovation, incomplete milking (IM) can be defined using a specialized software for a controlled reduction in milk withdrawal. Previously, it has been shown to decrease lactation-associated metabolic load without compromising udder health or subsequent productivity. The objective of this pilot study was to apply an established IM protocol during peak lactation under summer conditions and evaluate its effects on milk yield, metabolic and oxidative cell status. In summer 2024, clinically healthy cows in peak lactation were assigned to either complete milking (HCOMP; n=3; DIM 46±16; parity 2.3±0.3) or incomplete milking (HINCL; n=3; DIM 62±14; parity 2.3±0.3). In HINCL cows, milk withdrawal was reduced by 9% per day over 5.5 d to achieve an approximate 40% reduction (phase 1), followed by maintenance of this reduction for an additional 5.5 d (phase 2). One week prior to the intervention (baseline) and two weeks following the intervention served as reference periods. Milk yield and feed intake were recorded daily, and blood samples were collected on d -2, 6, 13, 20, and 27 relative to the start of IM for analysis of non-esterified fatty acids (NEFA), insulin-like growth factor-1 (IGF-1), derivatives of reactive oxygen metabolites (dROM), and advanced oxidation protein products (AOPP). Due to the limited sample size, results are presented descriptively. The average daily THI was 65±0.56 during phase 1, 63±0.89 during phase 2, and 70±0.46 in the week post-IM. Baseline milk yield ranged from 24.1 to 48.9 kg/d in HINCL and from 32.2 to 43.4 kg/d in HCOMP. In HINCL cows, the targeted reduction in milk withdrawal during the two IM phases was successfully achieved. During phase 1, NEFA concentrations were variable in both groups (HCOMP: 0.35–0.51 mmol/L; HINCL: 0.16–0.61 mmol/L). In phase 2, NEFA concentrations decreased and stabilized at lower levels (HCOMP: 0.11–0.18 mmol/L; HINCL: 0.10–0.12 mmol/L), then increased after cessation of IM. Baseline IGF-1 concentrations were comparable between groups (HCOMP: 81.1–126.8 ng/mL; HINCL: 97.9–138.9 ng/mL). While IGF-1 concentrations in both groups remained within baseline ranges during phase 1, HINCL cows showed a marked increase during phase 2 (166.9–303.0 ng/mL), whereas HCOMP cows showed only moderate variation (105.1–147.2 ng/mL). Baseline dROM values ranged from 42.4 to 104.9 µg H2O2 equivalent/mL in HINCL and from 54.9 to 121.9 µg H2O2 equivalent/mL in HCOMP. During phase 2, dROM values in HINCL cows increased markedly (111.0–138.8 µg H2O2 equivalent/mL), whereas HCOMP cows showed different trends by individual (93.6–116.9 µg H2O2 equivalent/mL). In contrast, AOPP values per g protein in HINCL decreased to a lower level in phase 2 (baseline: 0.97–1.18 µmol/g, phase 2: 0.74–1.03 µmol/g), whereas AOPP values in HCOMP were variable in both weeks (baseline: 0.63–1.19 µmol/g, phase 2: 0.95–1.32 µmol/g). Due to the limitations of this pilot study, it is not possible to provide a definitive answer to the targeted research question. Still, these preliminary observations support further investigation of IM as a potential strategy to modulate metabolic load during periods of thermal challenge in dairy cows.

Hoof Temperature Differences in Relation to Lameness Score

T. Bobić[1], N. Raguž[1], M. Oroz[1], M. Oroz[1], Ž. Radišić[1], P. Mijić[1], B. Lukić[1]
[1] Faculty of Agrobiotechnical Sciences Osijek, Department of Animal Production and Biotechnology, Vladimira Preloga 1, 31000 Osijek, Croatia

Besides mastitis and reproductive problems, lameness is one of the most common issues on dairy farms. Lameness has a negative effect on dairy herd performance and farm profitability due to its association with reduced milk yield, an increased risk of culling, impaired reproductive performance and also has negative impact on the cows' welfare. Early detection of cows with a lower degree of lameness is therefore essential to prevent progression to more severe stages and to improve overall herd welfare. Combining different methods, particularly those with the potential for automation, could significantly improve heard health monitoring and farm management. In order to improve the detection of lame cows on the farm, the aim of this study was to monitor hoof temperature and its relationship with the lameness score. Infrared temperature values were recorded at the coronary band (CB) of the cow's hooves. The four-point manual locomotion scoring system was used to assess four levels of lameness score (LS0 – LS3). The coronary band temperatures of unhealthy hooves were significantly higher comparably compared to those of healthy hooves. Under ambient recording conditions with air temperature of 14.27°C and relative humidity of 85.57%, significant differences in CB temperature were observed between cows with different lameness scores. The IR MEAN values of cows with LS0 (16.28°C) were significantly ($p < 0.05$) lower than those of cows with LS1 (17.59°C), LS2 (17.71°C) and were highly significantly lower compared to cows with LS3 (18.04°C). The results obtained in this study further advance the application of thermography by demonstrating that coronary band temperature distribution is influenced by hoof health status, ambient recording conditions, and lameness severity. The combination of methods used in this study enables early, non-invasive monitoring of hoof health and supports practical implementation within precision livestock farming frameworks. Although the practical implementation of automated systems still presents certain challenges, the combination of different methods that increase the reliability and accuracy of hoof disease detection may improve the prevention of lameness under farm conditions in the future, although further development is still required.

Improving Real-Time Sow and Piglet Behavior Detection Using Mixed-ELAN Architecture

Y. H. Choi[1], H. J. Kim[1], C. B. Lim[1], H. J. Park[1], J. E. Kim[1], Y. J. Min[1], Y. D. Jeong[1], H. Jung[1]
[1] Rural Development Administration, Swine Science Division, 114, Sinbang 1gil, 31000 Cheonan, South Korea

The need for effective livestock management has increased with the evolving dynamics of the agricultural industry, characterized by an aging workforce and the expansion of large-scale farming operations. Conventional monitoring methods, which rely predominantly on manual observation, are increasingly reaching their limits, necessitating the development of innovative automated solutions. In this study, a system for real-time sow and piglet behavior detection using an extended version of the ELAN architecture, known as mixed-ELAN, using diverse kernel sizes was presented. The standard convolutional operations within the ELAN framework were replaced by MixConv using diverse kernel sizes to enable superior feature learning capabilities. The proposed structure was applied to YOLOv7 and YOLOv9, and the experiments showed improvements of 1.5% and 2%, respectively, with a mean average precision of 0.805 and 0.796, compared to the original models. In addition, both models demonstrated significant performance improvements in behaviors critical for piglet growth and survival, such as crushing and lying down, highlighting the effectiveness of the proposed architecture. These advances underscore not only the potential of leveraging AI and computer vision technologies in agricultural practices, but also the benefits of the system in enhancing animal welfare and farm management efficiency. The proposed architecture, by providing a more sophisticated comprehension and real-time monitoring of livestock behavior, establishes higher benchmarks for smart farming technologies, and opens up possibilities for further innovation in livestock management.

AI-Based Early Warning System for Tail Biting Risk Detection suitable for Diverse Pig Husbandry Systems

K. Shehzad[1], D. S. Küster[2], D. S. Diers[3], P. D. .. H. J. M. Gómez[1], P. D. I. Traulsen[2]
[1] University of Oldenburg, Computer Science, Business Informatics, Ammerländer Heerstr. 114-118, 26129 Oldenburg, Germany, [2] Christian-Albrechtes University Kiel, Behavioural Informatics in Livestock Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [3] Landwirtschaftkammer Schleswig-Holstein, Fachbereichsleiterin Schweinehaltung, Versuchswesen, Aus- und Weiterbildung, Beratung ökologische Schweinehaltung, LVZ Futterkamp, 24327 Blekendorf, Germany

Tail biting represents one of the most persistent welfare and economic challenges in intensive pig production systems, leading to pain, tissue damage, infection, reduced growth performance and increased antibiotic use. Effective prevention depends on the early detection of behavioral changes preceding visible injury. Previous scientific initiatives, including "DigiSchwein" and related precision livestock farming projects, have demonstrated the feasibility of automated monitoring in pig husbandry. However, a scalable real-time early warning system specifically addressing tail biting risk under diverse farm conditions remains insufficiently established. This research is conducted within the framework of the "DeTail – Detection of Tail Biting" project funded by the European Innovation Partnership Agrar (EIP-Agrar) in Schleswig-Holstein and led by Landwirtschaftskammer Schleswig-Holstein in cooperation with the University of Oldenburg and Christian-Albrechts-University Kiel as scientific partners. The project aims to bridge this gap by integrating deep learning-based tail posture detection with motion-derived behavioral threshold modelling. Pigs exhibiting hanging tails are more frequently associated with stress, discomfort or ongoing biting events. Building upon these findings, this study implements a deep learning object detection architecture based on the YOLO framework. The model is trained via transfer learning on heterogeneous annotated datasets from multiple farms to detect individual pigs and classify tail posture states (tail up, tail down) together with posture categories (pig lying, pig not lying). For the prototype implementation, 392 training images and 158 validation images from ten pens across four farms were used. Despite the relatively small yet environmentally diverse dataset, transfer learning from a pre-trained model enabled stable convergence and effective feature reuse. The resulting performance achieved an overall mAP@0.5 of 0.816 across all classes. Class-wise precision–recall results show strong performance for pig not lying (0.964) and pig lying (0.909), while tail up (0.656) and tail down (0.736) reflect the increased complexity associated with small-object detection and class imbalance. Given the limited number of annotated tail instances, transfer learning proved essential for reliable discrimination between tail posture states. The system processes live video streams directly within the barn and aggregates detections at per-second intervals to generate structured behavioral time series. By combining tail posture distributions with motion-based activity thresholds, adaptive alarm points indicating elevated tail biting risk are estimated. Unlike earlier monitoring systems that relied primarily on offline video analysis, DeTail implements real-time processing within the barn environment, eliminating continuous video transfer and reducing bandwidth requirements. Alarm states are visualized in a dashboard interface accessible to farm operators, supporting timely intervention and enabling objective and continuous behavioral assessment. This system advances precision livestock farming toward welfare-oriented and demonstrate how AI can transition from experimental research to field-ready system under EU animal welfare directives.

Dietary Phosphorus Restriction Alters IGF Availability Independent of Hepatic GHR Signalling in Young Goats

K. Wittenberg[1], K. Hustedt[1], N. Schnepel[1], A. Hoeflich[2], A. S. Muscher-Banse[1]
[1] University of Veterinary Medicine Hannover Foundation, Institute of Physiology and Cell Biology, Bischofsholer Damm 15, 30173 Hannover, Germany, [2] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany

Reducing dietary phosphorus (P) and nitrogen (N) intake in livestock is discussed as a strategy to decrease nutrient excretion and environmental pollution. Owing to their capacity to recycle phosphate (Pi) and to utilise N via microbes in the forestomach, ruminants are a particularly promising group for reducing the P and N content of feeds. However, both nutrients are tightly linked to endocrine growth regulation. Dietary N restriction is known to impair the somatotropic axis via downregulation of hepatic growth hormone receptor (GHR) expression and reduced circulating IGF1 in young goats [1]. Dietary P restriction has also been associated with lower plasma IGF1 in these animals [2], but the underlying mechanisms remain unclear. We therefore aimed to characterise the effects of reduced P intake, alone or combined with N restriction, on the hepatic GHR-IGF1 axis in young goats and hypothesised that reduced P intake impairs IGF availability through mechanisms analogous to N restriction. Twenty-eight young male goats were assigned to four feeding groups (adequate vs reduced P, with or without concurrent N reduction; n = 7 per group) in a six-week feeding trial. After slaughter, blood and liver samples were collected. Hepatic mRNA expression of components of the GHR-IGF system (including IGF1, IGF2 and acid-labile subunit (ALS)) was quantified, and plasma protein concentration of IGF binding proteins (IGFBP2 and IGFBP3) was assessed. Data were analysed using two-way ANOVA; statistical significance was set at $P < 0.05$. Reduced P intake decreased hepatic IGF1 ($P < 0.05$) and ALS ($P < 0.01$) mRNA expression. At protein level, P restriction reduced circulating IGFBP3 concentration ($P < 0.01$) and lowered both the IGF1:IGFBP3 ratio ($P < 0.05$) and the IGFBP3:IGFBP2 ratio ($P < 0.001$). In contrast, hepatic GHR expression and indicators of downstream JAK–STAT signalling were not affected by reduced P intake. Hepatic IGF2 mRNA expression was increased under P restriction ($P < 0.05$). In conclusion, dietary P restriction reduces circulating IGF1 independently of hepatic GHR/JAK-STAT signalling. The concomitant reduction in circulating IGFBP3 and hepatic ALS mRNA suggests altered IGF transport and/or availability, potentially reflecting changes in ternary complex formation or stability. These findings indicate that the endocrine response to P restriction in young goats differs fundamentally from that observed under N restriction and should be considered when developing reduced P feeding strategies to mitigate environmental P pollution. Maternal methionine supplementation in low-protein diets during late gestation and lactation increases the performance and alters fecal microbiota of the sows and their offspring

Y. Duan[1], M. Wan[1], Y. Yin[1]
[1] Institute of Subtropical Agriculture, Chinese Academy of Sciences, No. 644 Yuanda Road, Furong District, Changsha Hunan 410125, China, 410125 Changsha, China

Methionine (Met) is known to enhance antioxidant defense and reproductive efficiency in sows, but its role under low-protein feeding conditions is unclear. This study evaluated the effects of Met supplementation on lactation performance, antioxidant status, and gut microbiota of sows and their piglets. Sixty-six multiparous sows were assigned to a normal protein diet (18% crude protein, CP) or low-protein diets (15% CP) containing graded standardized ileal digestible Met levels from day 107 of gestation to day 21 of lactation. Compared with normal protein diet, low-protein diets supplemented with 0.30% Met significantly ($P < 0.05$) reduced serum urea nitrogen in sows at weaning and improved milk yield, piglet growth, and post-weaning estrus interval. In addition, 0.30% Met supplementation resulted in enhanced milk immunoglobulin M, glutathione, and taurine concentrations and increased serum antioxidant enzyme activities. Microbiome analysis indicated higher relative abundance of Christensenellaceae_R-7_group in piglets from the 0.30% Met group, positively correlated with growth traits. These findings suggest that a 0.30% Met level in a 15% CP diet supports sow performance and piglet development comparable to normal protein feeding through improved antioxidant capacity and beneficial microbial modulation.

Comparison between copper sources and benzoic acid supplementation in weaned piglets

Y. J. Manaig[1], L. Blavi[2], A. Rigo Monteiro[1], S. Durosoy[1], S. Tibble[2], F. Gonzalez[2]
[1] Animine, 10 Rue Léon Rey Grange, 74960 Annecy, France, [2] AB Neo, PL Fraga, C/ Comunidad de Murcia, parc. LIE-1-03, 22520 Fraga, Spain

Monovalent copper has been reported to exhibit stronger antibacterial properties than divalent copper. Benzoic acid is commonly used in pig nutrition as a feed preservative and gut health additive and has been reported to form stable complexes with cuprous ions in aqueous environments, potentially stabilizing copper in its monovalent form. This study evaluated the effect of benzoic acid supplementation on the efficacy of dietary copper from monovalent (CR) or chelated divalent (MHA-Cu) sources in weaned piglets. A total of 1,200 piglets (Danbred × Pietrain), weaned at 24 days of age with an average body weight of 5.6 kg, were allocated to a 2 × 2 factorial design evaluating copper source (CR vs. MHA-Cu) and benzoic acid inclusion (0 or 0.5%). Four treatments were tested with 12 replicates of 25 pigs each. The trial lasted 42 days and consisted of three phases (1–14 d, 15–28 d, and 29–42 d). Copper was supplied at 140 ppm during phases 1 and 2 and 25 ppm during phase 3. Growth performance, mortality and morbidity, medication use, and fecal parameters (score and pH) were recorded. Data were analyzed using the General Linear Model procedure of JMP (version 17.0) with the pen serving as the experimental unit. During phase (Phase 2), pigs fed CR showed significantly higher feed intake compared with pigs fed MHA-Cu ($P < 0.05$). No significant differences in body weight were observed among treatments, although pigs fed CR with benzoic acid displayed numerically higher average daily gain and improved feed conversion ratio over the 42-day period compared with both MHA-Cu treatments. In Phase 1, pigs receiving CR showed the lowest proportion of individually medicated animals, indicating improved adaptation to weaning. Overall mortality and morbidity tended to be higher in pigs fed MHA-Cu ($P < 0.10$). During Phase 2, pigs receiving MHA-Cu alone exhibited higher fecal scores compared with pigs fed CR or MHA-Cu with benzoic acid, indicating reduced intestinal stability. A tendency for higher fecal pH was observed in pigs fed MHA-Cu with benzoic acid compared with CR and MHA-Cu alone, which may reflect reduced hindgut fermentation due to antimicrobial activity earlier in the digestive tract. No differences were detected in total fecal enterobacteria counts among treatments. Overall, CR supported higher feed intake during the critical starter phase and numerically improved growth efficiency, health status, and fecal consistency. Benzoic acid supplementation did not consistently enhance responses across copper sources, indicating that the primary performance benefit was driven by the copper source. These results demonstrate that monovalent copper is a reliable alternative to chelated copper sources in commercial weaned piglet diets.

Effect of trace mineral source on copper, manganese, and zinc concentrations in ruminal content and feces of crossbred steers in grazing conditions

F. P. Leonel[1], D. Brito De Araujo[2], K. V. Z. Augusto[3], M. E. L. Rezende[1], T. Engle[4]
[1] Federal University of Sao Joao Del Rey, Department of Animal Science, Rodovia 494, s/n, 36301-360 Sao Joao Del Rey, Brazil, [2] Nutreco Nederland, Selko, Stationstraat 77, 3811MH Amersfoort, Netherlands, [3] Trouw Nutrition Brazil, Av. Jose Rocha Bonfim, 214, 13080-650 Campinas, Brazil, [4] Colorado State University, Department of Animal Sciences, 350 W. Pitkin St., 80523 Fort Collins, United States

Copper, Mn, and Zn from highly soluble sources in the rumen, can strongly bind to fiber, reducing absorption in the small intestine. Thus, our objective was to evaluate the effect of different trace mineral sources on Cu, Mn, and Zn concentrations in the ruminal contents and feces of crossbred steers under grazing conditions. Four steers were assigned to a 4×4 Latin square design: Control (No supplemental Cu, Mn, or Zn); Cu, Mn, and Zn-sulfate; Cu, Mn, and Zn-organic; and Cu, Mn, and Zn-hydroxychloride. Samples of feces and ruminal contents were collected at the end of each period and analyzed for Cu, Mn, and Zn concentrations. Data were subjected to analysis of variance ($P < 0.05$), and the means were separate using the SNK multiple comparison test. No treatment x animal x period interactions were observed ($P > 0.05$). Fecal Cu concentrations were greater ($P < 0.05$) in animals receiving sulfate forms of Cu, Mn, and Zn compared to all other treatments. Fecal Cu concentrations were similar between hydroxychloride, organic, and control steers. Fecal Mn concentrations were greater ($P < 0.05$) in steers receiving Mn-sulfate compared to all other treatments. Fecal Mn concentrations were similar between steers receiving hydroxychloride and organic forms of Mn. Steers receiving Mn in sulfate, hydroxychloride, and organic forms had greater fecal Mn compared to controls. A similar pattern was observed for fecal Zn concentrations. Copper, Mn, and Zn concentrations in the solid fraction of the ruminal contents were greater ($P< 0.05$) for the steers receiving sulfate forms compared to all other treatments. Copper, Mn, and Zn concentrations in the solid fraction of the ruminal contents were similar between steers receiving hydroxychloride, organic, and control diets. Overall, sulfate sources increased the concentrations of Cu, Mn, and Zn in both feces and in the solid fraction of the ruminal contents, suggesting that Cu, Mn, and Zn from sulfate bind strongly to digesta.

Calcium, bone and energy metabolism of dairy goats supplemented with poplar leaves during early lactation

K. Helffenstein[1], M. R. Wilkens[2], B. Kuhla[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm- Stahl Allee 2, 18196 Dummerstorf, Germany,
[2] Leipzig University, Institute of Animal Nutrition, Nutrition Diseases and Dietetics, An den Tierkliniken 19, 04103 Leipzig, Germany

Early lactating dairy goats experience increased energy and nutrient demands for colostrum and milk production, which cannot be met by a sufficient increase in feed intake. As a consequence, does mobilize, among others, their fat and bone reserves, thereby entering negative energy and Ca balances. Black poplar leaves are rich in metabolizable energy and Ca, suggesting they are a valuable feed source for meeting the increased requirements of early lactation. Therefore, the objective of this study was to investigate the effect of black poplar supplementation on the Ca, bone and energy metabolism of early lactating dairy goats. Sixteen one-year old Saanen goats in the third trimester of pregnancy were group housed at least four 4 weeks until parturition. Goats were fed hay ad libitum, wheat, 0.2 to 0.3 kg wheat daily and had access to a mineral lick stone. After birth, access to the mineral lick stone was blocked and dams and their lambs were moved to individual pens and assigned to one of two groups. One group was fed 700 g of black poplar hybrid foliage, gradual increase in wheat (100 to 250 g from week 1 to 5 postpartum), and hay for ad libitum intake (POPLAR, n = 9). The control group received only hay for ad libitum intake and wheat as described (CON; n = 7). Individual foliage and hay intakes were recorded daily and dams were blood sampled weekly starting 1 week before the calculated lambing date. Both groups had a comparable dry matter intake and plasma glucose and non-esterified fatty acid concentrations. However, POPLAR goats tended to have lower plasma osteocalcin concentrations postpartum and had a lower osteocalcin/CTX ratio and lower serum Ca concentrations in week 2 pp postpartum. These results indicate that black poplar supplementation had no impact on the energy status but compromised calcium and bone metabolism, the latter likely due to tannins hindering intestinal Ca absorption. Therefore, black poplar supplementation cannot be recommended as feed supplement in early lactation.

Discovering the plasma metabolic fingerprint of heat-stressed Holstein dairy cows

F. Koch[1], D. Rico[2], R. Mandal[3], B. Kuhla[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] Centre de recherche en sciences animales de Deschambault (CRSAD), 120-A Chemin du Roy, G0A 1S0 Deschambault (QC), Canada, [3] University of Alberta, Dept. of Biological Sciences, CW 405, T6G 2E9 Edmonton, Canada

Heat stress can impact dairy cow feeding behavior, ruminal function, intermediary metabolism and nutrient partitioning. Wholesale changes in plasma metabolic profiles may serve as a tool to provide further mechanistic insights in regards to the heat stress phenotype. This study aimed to elucidate the plasma metabolic profile differences between cows under heat stress or feed restriction in thermoneutrality. Thirty German Holstein cows (169 ± 9 days in milk; DIM) were kept in a climate chamber under thermoneutral conditions (16°C; 63% relative humidity (RH); temperature-humidity-index (THI) 60) for 6 days and fed a total mixed ration for ad libitum intake. Subsequently, 10 cows were exposed to 28°C (heat stress, HS; 52% RH; THI 76) for 6 days, whilst 10 cows remained under thermoneutral conditions (CON). To mimic the lower feed intake under HS, pair-feeding using a diet identical to the HS group was applied to the CON group. Milk yield, dry matter (DMI) and water intake were determined daily. Rectal temperature (RT) and respiration frequency (RF) were measured twice daily. Blood samples were collected on day 6 after treatment for targeted metabolomic analysis. Plasma samples were subjected to targeted quantitative metabolomics using reverse-phase HPLC/MS/MS. Statistical analysis of plasma metabolites was performed by utilizing MetaboAnalyst 6.0. Daily measurements on the same animal were analyzed with a repeated measure ANOVA using the MIXED procedure of SAS (V9.4) with the fixed effects of treatment (HS, CON, PF), time (day), and treatment by time interaction; and DIM served as a covariate. Multiple comparisons were performed with the Tukey-Kramer test. Milk yield was reduced by 25% in HS than CON cows, whilst in the PF group, milk yield decreased by 13% relative to the CON group ($P<0.05$, respectively). DMI was lower in HS and PF than CON cows, whereas water intake was higher in HS than PF and CON cows ($P<0.05$, respectively). RT and RF increased in HS than CON and PF cows ($P<0.01$, respectively). In total, 164 plasma metabolites were detected, of which 53 metabolite concentrations were differently abundant. HS cows exhibited higher plasma concentrations of creatinine, methylhistidine, acetylornithine, sphingomyelins SM (OH) C22:1, C22:2, SM C24:1 and methionine sulfoxide concentrations than CON and PF cows, whilst butyrylcarnitine concentration was significantly lower ($P<0.05$). Oleic acid, linoleic acid, margaric acid, palmitoleic acid, butyric acid, docosapentaenoic acid, heptanoic acid, methylmalonic acid myristic acid and pentadecylic acid concentrations were higher in PF than in HS and CON cows, whereas hippuric acid, alanine, uric acid, tyrosine, and propionic acid concentrations were lower in PF than in CON and HS cows (all $P<0.05$). To conclude, heat stress increased the concentrations of metabolites related to skeletal muscle proteolysis, oxidative protein modification and sphingolipid metabolism, independent of reduced feed intake. Plasma profile of cows with a reduced feed intake at thermoneutrality suggests increased fatty acid mobilization, altered rumen-derived metabolites, and enhanced phospholipid turnover.

Proteome characterization of milk extracellular vesicles isolated from cows during heat stress

Y. Dadi[1], M. Delosiere[2], L. De Matos[1,3], A. Delavaud[2], M. Penati[1], D. Viala[2,4], G. Salvi[1], O. Balbi[1], A. Imbert[2], P. De Palo[5], A. Maggiolino[5], F. Ceciliani[1], M. Bonnet[2], C. Lecchi[1,3]
[1] University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Universita 6, 26900 Lodi, Italy, [2] INRAE, Université Clermont Auvergne, Vetagro Sup, UMRH, Route de Theix, 63122 Saint-Genès-Champanelle, France, [3] MOOVET DXC S.r.l., Precision Diagnostics LAB for Animal Health – Spin-off of the University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Universita 6, 26900 Lodi, Italy, [4] INRAE, Université Clermont Auvergne, Vetagro Sup, PFEM, Route de Theix, 63122 Saint-Genès-Champanelle, France, [5] University of Bari A. Moro, Department of Veterinary Medicine, SP 62, 70010 Valenzano, Italy

Heat stress (HS), intensified by climate change, threatens dairy cow welfare and productivity, yet early molecular adaptations remain unclear. Milk-derived extracellular vesicles (mEVs) reflect the physiological state of mammary cells and represent promising non-invasive biomarkers. This study evaluated the effects of acute HS on the mEV proteome in lactating Holstein and Brown Swiss cows. Fourteen multiparous cows (7 Holstein, 7 Brown Swiss) were exposed to thermoneutral (TN; THI < 68) and HS (THI 69–84) conditions by deactivating the cooling system in a commercial farm (July 2023). Cows were sampled under TN conditions and again after 24 h of HS exposure. Milk and blood samples were collected at 3 p.m. under both conditions. Systemic biomarkers included adiponectin, leptin, haptoglobin, and lactoferrin, along with oxidative stress indicators (d-ROM, FRAP, and AOPP). mEVs were isolated by ultracentrifugation and size-exclusion chromatography, characterized by nanoparticle tracking analysis and transmission electron microscopy, and analyzed by nano–LC–MS/MS. Proteomic data were identified by MASCOT and quantified by Progenesis QI using the Bos taurus UniProt database. The differential abundance of proteins was assessed using a univariate analysis with Benjamini-Hochberg correction, with HS as the main fixed effect. This was complemented by multi-level sparse partial least squares discriminant analysis(sPLS-DA), in which the proteins with non-zero loadings in the most discriminating HS component were retained and listed by using R software. Acute HS induced moderate physiological changes without affecting milk yield or most systemic biomarkers. However, significant remodeling of the mEV proteome was observed. Overall, 134 proteins were differentially abundant between TN and HS conditions (24 increased, 110 decreased under HS). Multivariate analysis showed clear separation between groups, with positive loadings under HS mainly driven by signal peptidase complex subunit 3, DnaJ heat shock protein family member C3, alpha-S2-casein, and keratin type II cytoskeletal 71. These proteins are associated with secretory activity, stress response, and structural organization. Functional enrichment indicated modulation of metabolic, immune and stress-response pathways. These results demonstrate that acute HS markedly alters mEV protein cargo, highlighting mEVs as sensitive indicators of early heat stress adaptation in dairy cows.

Heat stress induced alterations in the hepatic lipid metabolism in primiparous dairy cows

S. M. Sarkar[1], D. Dannenberger[1], D. Rico[2], B. Kuhla[1], F. Koch[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany,
[2] Centre de recherche en sciences animales de Deschambault (CRSAD), 120-A Chemin du Roy, G0A1S0 Deschambault (QC), Canada

Heat stress is a global challenge for dairy cows due to rising environmental temperatures. Heat stress has shown to induce metabolic adaptations, such as reduced lipolytic activity and nutrients prioritization, to cope with increased heat and concomitantly reduced feed intake. This study aims to investigate heat stress-induced alterations in the hepatic lipid metabolism in Holstein dairy cows. In this study, 30 mid-lactating, non-pregnant German Holstein dairy cows were randomly selected and acclimated for six days to thermoneutral conditions (TN) at 16°C, 63% relative humidity (RH), temperature-humidity-index (THI) of 60 in climate-controlled chambers. Thereafter, animals were evenly allocated to heat stress (HS), control (CON), or pair-feeding (PF) group (n = 10 cows per group) and subjected to a 7-day trial. HS group was exposed to 28°C, 52% RH and THI of 76, whereas CON and PF groups remained under TN. On trial day 7, cows were slaughtered and liver samples were collected. Gene expression related to lipid metabolism was quantified by RT-qPCR. Hepatic fat content and fatty acids (FA) profiles (percent of total FA) were determined using high-resolution gas chromatography. Statistical analyses were conducted using linear mixed models in R. HS cows showed a tendency towards lower percentages of total liver fat ($P<0.09$) and monounsaturated FA (MUFA) than PF cows, whereas PF cows had higher percentage of total fat and MUFA than CON cows ($P<0.001$, respectively). Saturated FA were comparable among the groups. Further, HS cows had higher percentage of n-3 PUFA than CON and PF cows and higher n-6 PUFA than PF cows ($P<0.001$, respectively). In total, 31 FA were detected, of which 25 FA were differently abundant and 6 FA were unaltered among the groups. HS cows tended to have lower C14:0 ($P<0.09$) and significantly lower C16:0 percentage than PF cows ($P<0.001$), but higher percentage of C17:0 and C18:0 than PF cows ($P<0.05$, respectively). In addition, HS cows had a higher percentage of C16:0 but lower C17:0, C21:0 and C23:0 percentages ($P<0.05$, respectively) and a tendency of a lower C18:0 portion ($P<0.09$) compared to CON cows. Percentages of C16:1cis-9, C17:1cis-9, C18:1cis-9, C18:1trans-9 and C18:1trans-11 were lower in HS than PF cows ($P<0.05$, respectively). A lower proportion of C18:1trans-9 but higher C18:1trans-11 was found in HS than CON cows ($P < 0.001$, respectively). The PUFA fraction had higher C18:2cis-9trans-11 and C20:3n-3 and lower C18:3n-3, C18:4n-3, C20:3n-6 and C20:5n-3 (EPA) percentages in HS than CON cows ($P<0.05$, respectively). Percentage of C20:3n-3, C20:3n-6, C20:2n-6, C20:4n-6, and C20:5n-3 tended or were significantly higher in HS than PF group ($P<0.09$, respectively). The mRNA abundance of hepatic sterol-CoA desaturase (SCD1) was lower in HS and PF than in CON cows ($P<0.001$, respectively). Similarly, mRNA abundance of acetyl-CoA carboxylase (ACACA) tended to be lower in HS than in CON cows ($P<0.09$), whilst mRNA abundances of fatty acid synthase (FASN) and ACACA tended ($P<0.09$) or were lower ($P<0.05$) in the liver of PF than CON cows. In conclusion, differences in hepatic fatty acid composition between the HS and the other two groups are likely due to differences in the mobilization of extrahepatic fat and the concomitant suppression of de novo lipogenesis in HS and PF cows. This suggests that the amount and profile of circulating fatty acids may have influenced hepatic lipid composition in the liver of HS and ectopic fat storage in the liver of PF cows.

Predicting subclinical ketosis in Holstein dairy cows using fatty acid content in milk

A. R. Sharifi[1], M. Zschiesche[2,4], N. Gengler[3], J. Hummel[4], H. Jansen[4,5]
[1] University of Goettingen, Animal Breeding and Genetics, Albrecht-Thaer-Weg 3, 37075 Goettingen, Germany, [2] Landesanstalt für Landwirtschaft und Gartenbau Sachsen-Anhalt, Lindenstraße 18, 39606 Iden, Germany, [3] Teaching and Research Center, Gembloux Agro-Bio Tech, University of Liège, Pass. des Déportés 2, 5030 Gembloux, Belgium, [4] University of Goettingen, Division of Ruminant Nutrition, Kellnerweg 6, 37077 Goettingen, Germany, [5] Chamber of Agriculture Lower Saxony, Mars-la-Tour-Str. 1 - 13, 26121 Oldenburg, Germany

Subclinical ketosis (SCK) is a metabolic disorder in dairy cows that occurs during the early postpartum period and is associated with reduced feed intake, decreased milk yield, increased risk of clinical ketosis, displaced abomasum, and impaired fertility. It is characterized by elevated levels of ketone bodies in the blood, milk, and urine. A blood serum level of β-hydroxybutyric acid (BHBA) of 1.2 mmol/l is proposed as a suitable threshold value for the initial detection and treatment of SCK. The milk fat content and fatty acid (FA) profile in particular, are promising indicators of negative energy balance during early stages of lactation. The main objective of this study was to evaluate whether specific milk FA profiles can provide precise indicators for identifying cows at risk of SCK, using their association with BHBA as a diagnostic reference parameter. The data was collected on ten dairy farms in Germany. On each farm, ten Holstein dairy cows were selected for the study. The primary criterion for selection was the nearest anticipated calving date (2–3 weeks) in relation to the initiation of data collection. The data collection process was conducted over a period of 11 days per farm. BHBA was determined on days 2, 4, 9 and 11 after milking using blood samples. The FA profile was determined using mid-infrared spectra-based prediction equations. The quantities of FA were calculated as the proportion of milk fat. Milk fat originates from the synthesis of FA in the mammary gland, from FA supplied by the diet or from FA released from body fat during a negative energy balance. The following FA were selected for the ensuing analysis: C4:0, C6:0, C8:0, C10:0, C12:0, C14:0, C14:1, C15:0, C15:0 anteiso, C15:0 iso, C16:0, C16:1 cis, C17:0, C18:0, C18:1 cis-9, C18:2 cis-9 cis-12, C18:2 cis-9 trans-11, C18:3 cis-9 cis-12 cis-15, and total C18:1 trans. Due to multicollinearity among the different FA, they were clustered (CL) into 9 groups of correlated milk FA by cluster analysis. A binary parameter (0 = SCK, 1 = no SCK) was created and used as the response variable in relation to the FA within each cluster. The statistical analysis to predict the occurrence of SCK was performed using a generalised linear model with a logit link function, considering parity as a fixed effect and FA as a regression term. The results of the study revealed a significant negative association between the concentrations of C14:0 ($P<0.0001$) and C8:0 ($P=0.0004$) (CL4) and the occurrence of SCK. In contrast, C4:0 (CL5) exhibited a significant positive ($P=0.008$) association with SCK, despite the fact that the FA in both CLs are predominantly synthesised in the mammary gland. A positive association was found between C18:0 (CL7) ($P<0.0001$), C18:1 cis-9 ($P<0.0001$) (CL9) and an increased risk of SCK. These long-chain FA are primarily derived from the mobilisation of body fat reserves. Furthermore, a negative association was found between C15:0 ($P<0.0001$) (CL1), an odd chain FA produced mainly by microbial fermentation, and the risk of SCK. The correlation between the FA mentioned above and BHB ranged from -0.5 to 0.34. This study shows that specific milk FAs are strongly linked to the risk of SCK in Holstein dairy cows and can serve as non-invasive indicators for its early detection.

Can milk fatty acid profile serve as a predictor of different types of hyperketolactia in dairy cows?

J. Kwaśniewska[1,2], W. Młocek[3], K. Słoniewski[2], R. J. Van Saun[4], Z. M. Kowalski[1]
[1] Department of Animal Nutrition and Biotechnology, and Fisheries, University of Agriculture in Krakow, Aleja Mickiewicza 21, 31-120 Krakow, Poland, [2] Polish Federation of Cattle Breeders and Dairy Farmers, Zurawia 22, 00-515 Warsaw, Poland, [3] Department of Applied Mathematics, University of Agriculture in Krakow, Aleja Mickiewicza 21, 31-120 Krakow, Poland, [4] Department of Veterinary and Biomedical Sciences, College of Agricultural Sciences, The Pennsylvania State University, University Park, PA 16802 Old Main, United States

This study aimed to explore relationships between selected fatty acids (FA) in milk and concentrations of beta-hydroxybutyric acid (mBHB) and acetone (mACE), and to develop models predicting the risk of hyperketolactia (HYKL) types for potential use in milk recording in Poland. Data from 1,023,838 test-day samples provided by the Polish Federation of Cattle Breeders and Dairy Farmers (PFHBiPM) between 10 August 2017 and 28 December 2019 were analyzed. Samples were collected from Holstein–Friesian cows at 6–60 DIM. Relationships between milk components were assessed using Spearman's rank correlations. Samples were classified into healthy (NKL) and hyperketolactic (HYKL) groups based on thresholds (de Roos et al., 2007): NKL (mACE < 0.15 mmol/L and mBHB < 0.1 mmol/L) and HYKL (mACE ≥ 0.15 mmol/L or mBHB ≥ 0.1 mmol/L; Kowalski et al., 2021). In addition, HYKL milk samples were further classified into three HYKL groups: HYKLACE (mACE ≥ 0.15 mmol/L and mBHB < 0.1 mmol/L), HYKLBHB (mACE < 0.15 mmol/L and mBHB ≥ 0.1 mmol/L), and HYKLACEBHB (mACE ≥ 0.15 mmol/L and mBHB ≥ 0.1 mmol/L). Multiclass logistic regression models were developed using DIM and selected milk traits (mBHB, mACE, MF, MP, LCFA, SCFA, MUFA, C16:0, C14:0, C18:0, C18:1) as predictors and HYKL groups as outcomes. Principal component analysis (PCA) was used to select key predictors. A strong positive relationship was found between mACE and mBHB (r = 0.78). Negative correlations were observed between mACE and the contents of SCFA and C14:0 (r = –0.26 and –0.23, respectively). The content of MP was weakly negatively correlated with both mACE and mBHB (r = –0.16 and –0.21). The strongest associations were observed between mACE and LCFA and TUFA (r = 0.45 and 0.43), as well as between mACE and C18:1 and C18:0 (r = 0.45 and 0.44). Similar relationships were found for mBHB (r = 0.49 for LCFA, r = 0.44 for TUFA, r = 0.46 for C18:1, and r = 0.48 for C18:0). The correlations observed between mBHB, mACE, and FA contents provide a foundation for further research on the use of these parameters in diagnostic models for monitoring dairy cow health. The most important predictors of assignment to particular HYKL groups were the ketone bodies, i.e., mACE and mBHB. The contents of C18:0 and C18:1 were also relatively strong predictors. In predicting HYKLACE, the most important variables were MUFA, TUFA, LCFA, C18:1, C18:0, MY, MP, C14:0, and DIM. In predicting HYKLBHB, the most important variables were mBHB, MY, MP, C14:0, C16:0, MF, C18:0, C18:1, and LCFA. In contrast, in predicting HYKLACEBHB, the most important variables were mBHB, mACE, DIM, SCFA, and C14:0.The developed models showed the lowest predictive accuracy for the HYKLACEBHB group, indicating greater complexity in correctly classifying cases where both ketone bodies are elevated. Overall, the results confirm that milk fatty acid profiles, particularly LCFA, MUFA, SCFA, C18:0, and C18:1, are significantly associated with ketone body concentrations and can be used as indicators in predictive models. Inclusion of selected FA improves the ability to differentiate between specific types of hyperketolactia.

Associations between hyperketonaemia, glucose and phosphate

M. O. Matthäi[1], G. Köller[2], S. U. Kononov[1], J. Rehage[3], L. H. Baumgard[4], M. R. Wilkens[1]
[1] Leipzig University, Institute of Animal Nutrition, Nutrition Diseases and Dietetics, An den Tierkliniken 9, 04103 Leipzig, Germany, [2] Leipzig University, Large Animal Clinic Laboratory, An den Tierkliniken 11, 04103 Leipzig, Germany, [3] University of Veterinary Medicine, Hannover, Clinic for Cattle, Bischofsholer Damm 15, 30173 Hannover, Germany, [4] Iowa State University, Department of Animal Science, 313J Kildee Hall, 50011 Ames, United States

Hyperketonaemia (HK) develops when acetyl-CoA, mainly derived from non-esterified fatty acid (NEFA) oxidation, cannot be further metabolised in the citric acid cycle. In the present study, 48 cows from two dairy herds (Holstein-Friesian and Simmental) were monitored due to a known increased risk of clinical ketosis and associated health issues. Starting with day 1, animals were blood sampled weekly until 32 days in milk (DIM) and treated with oral propylene glycol for five days when serum β-hydroxybutyrate (BHB), determined using a hand-held device, exceeded 1.2 mM, and additionally with intravenous glucose monohydrate and fructose once when BHB exceeded 1.7 mM. If animals were treated intravenously, they were sampled again after 24 h and received a second i.v. treatment if BHB was still > 1.7 mM. During the observation period, 16 out of the 48 cows presented with HK and were treated either orally or intravenously once (HK1). Another eight HK cows were treated between three and twelve times (HK2). To gain further insight into intermediary metabolism and to evaluate whether animals at risk could be identified earlier, we analysed serum for NEFA, glucose, calcium and phosphate using standard methods conducted at the Large Animal Clinic Laboratory. Group differences were analysed using a mixed model (time, grade and interaction) followed by Tukey´s multiple comparisons test (grade). First test-day milk yield was higher in HK2 animals compared to non-ketonaemic cows (NHK) but did not differ from HK1 (HK2 vs. NHK: $P < 0.001$). On the second test-day, milk yield in HK2 also differed from HK1 (HK2 vs. NHK: $P = 0.003$; HK2 vs. HK1: $P = 0.029$). The body condition score of HK2 cows was lower compared to the other two groups at 16 DIM (HK2 vs. NHK: $P = 0.031$; HK2 vs. HK1: $P = 0.040$), 24 DIM (HK2 vs. NHK: $P = 0.008$; HK2 vs. HK1: $P = 0.016$), and 32 DIM (HK2 vs. NHK: $P = 0.032$; HK2 vs. HK1: $P = 0.042$). Serum NEFA and BHB were increased in both HK groups compared to NHK during the entire observation period except for 1 DIM, while a significant difference between HK1 and HK2 could only be detected for NEFA on 8 DIM ($P = 0.008$) and 16 DIM ($P = 0.030$), but not for BHB. Calcium concentrations did not differ between the groups, while glucose was deceased in HK1 cows compared to NHK. The most notable finding in HK2 animals was a significantly lower product of serum glucose and phosphate concentrations in comparison to both NHK and HK1 cows on 8 DIM (HK2 vs. NHK: $P < 0.001$; HK2 vs. HK1: $P = 0.001$) and 16 DIM (HK2 vs. NHK: $P = 0.003$; HK2 vs. HK1: $P = 0.014$) and compared to NHK on 24 DIM ($P = 0.035$) and 32 DIM ($P = 0.042$). When expressed relative to NEFA, a significant reduction compared to the NHK and HK2 groups was already evident on 1 DIM (HK2 vs. NHK: $P = 0.005$; HK2 vs. HK1: $P = 0.006$) and persisted until 24 DIM. This observation might indicate that the combination of these parameters could be associated with metabolic alterations linked to high milk yield; adjustments that might also explain the unresponsiveness of serum BHB to treatment in HK2. Such homeorhetic adjustments, however, may be potential risk factors for morbidity. Whether the product of glucose and phosphate related to NEFA on 1 DIM might be suitable for the early identification of cows that require special attention and possibly support would need to be investigated in a larger sample.

The association of postpartum inflammatory-metabolic status with early-lactation milk yield in clinically healthy cows

N. Taechachokevivat[1], L. M. Avila-Granados[1], J. Grantz[1], A. Ueda[1], R. Neves[1]
[1] Purdue University, Veterinary Clinical Sciences, 625 Harrison St, 47906 West Lafayette, United States

In the early postpartum, most dairy cows experience some systemic inflammation from processes such as tissue injury and remodeling, microbial exposure in the uterus, mammary gland, and gastrointestinal tract, lipid mobilization, and oxidative stress. Although controlled inflammation is normal in the periparturient period, excessive inflammation is associated with reduced milk yield. Concurrently, decreased dry matter intake and increased energy and nutrient demands for milk production predispose cows to metabolic disorders such as subclinical hypocalcemia (SCH) and hyperketonemia (HYK), which are also associated with lower production. However, it is unclear whether the combination of excessive inflammation and metabolic disorders affects milk yield differently than either condition alone. We hypothesized that cows with both excessive inflammation and ≥1 metabolic disorder will have lower milk yield than cows with one or neither condition. Our objective was to evaluate the association of inflammatory-metabolic status with milk yield in early lactation (SCH and HYK were combined to represent overall metabolic dysfunction). Blood samples were collected from 513 Holstein cows from 2 herds at 1, 2, 3, 5, and 7 days in milk (DIM) to measure plasma haptoglobin (Hp), total calcium (Ca), and blood β-hydroxybutyrate (BHB). Only cows without metritis, clinical mastitis, milk fever, clinical ketosis, or displaced abomasum within 21 DIM were included (final n = 428). Excessive inflammation was defined as Hp above threshold on ≥2 days using parity- and DIM-specific thresholds from our previous study (primiparous: 0.4, 0.4, and 0.6 g/L at 3, 5, and 7 DIM; multiparous: 0.2, 0.3, 0.5, and 0.1 g/L at 1, 3, 5, and 7 DIM). Subclinical hypocalcemia was defined as total Ca ≤2.15 mmol/L at 2 DIM in primiparous cows and ≤2.20 mmol/L at 3 and/or 5 DIM in multiparous cows (McArt and Neves (2020); as 4 DIM was not sampled in our study, we applied multiparous threshold to the closest time points), and HYK as BHB ≥1.2 mmol/L at 3, 5, and/or 7 DIM. Cows were categorized into four inflammatory-metabolic groups: NON (no excessive inflammation, SCH, or HYK), MET (SCH and/or HYK only), INF (excessive inflammation only), and INF+MET (excessive inflammation with SCH and/or HYK). Repeated measures linear mixed models were used to assess associations between inflammatory-metabolic status and milk yield through wk 12 of lactation. In multiparous cows, INF and INF+MET cows produced 4-9 kg/d less than NON and MET cows during the first 4 wk of lactation, and INF+MET cows produced 5 kg/d less than INF cows in wk 1. In primiparous cows, INF cows produced 6-8 kg/d less milk than MET cows in wk 1 and 3 of lactation and 6–8 kg/d less than INF+MET cows from wk 4 to 12, whereas INF+MET cows tended to produce less than MET cows only in wk 1. Overall, excessive inflammation was associated with lower milk yield in multiparous cows regardless of metabolic status (NON & MET > INF & INF+MET). In primiparous cows, inflammation was associated with lower milk yield in the first wk regardless of metabolic status (NON & MET > INF & INF+MET); however, from wk 2 onward, cows with both inflammation and metabolic disorders showed production recovery, whereas cows with inflammation alone had decreased milk yield throughout the 12 weeks (NON & MET & INF+MET > INF). These findings suggest that parity modifies the association between inflammatory–metabolic status and early-lactation milk yield, with inflammation appearing to be the primary factor associated with reduced production in multiparous cows, whereas concurrent metabolic disorders may alter this relationship in primiparous cows.

Effect of phosphate source on phosphorus digestibility in cows

C. Omphalius[1], A. Bonnel[2], C. Gousset[2], B. Ribeiro[2], S. Julliand[1]
[1] LAB TO FIELD, 26 bd du Docteur Petitjean, 21000 DIJON, France, [2] Phosphea, 27 av Franklin Roosevelt, 35400 SAINT-MALO, France

Phosphorus (P) is an essential mineral for the production and health of dairy cows. As basic diets do not always meet nutritional requirements, an inorganic phosphate (Pi) supplement may be necessary to ensure adequate P intake. However, P digestibility (dP) may vary among Pi sources and these variations remain poorly described. To clarify the dP values of various products used in cow nutrition, a digestibility study was conducted. At the same time, the impact of different forms of Pi on P metabolism was investigated, as well as the impact on the total digestibility of other dietary components. Twelve Prim'Holstein cows (560±68 kg, 5.5±1.7 yo) were divided into six homogeneous groups of two animals and assigned to a 6×6 Latin Square (with 7-day periods). The diet, individually monitored, was formulated to meet 100% of individual energy and protein requirements, but only 75% of P requirements. To meet 100% of theoretical P requirements, additional P was provided with one of the 5 following Pi supplements: dicalcium phosphate (DCP), monocalcium phosphate (MCP), monoammonium phosphate (MAP), monosodium phosphate (MSP), magnesium phosphate (MagP). During one of the experimental period of the Latin Square, no supplement was provided (control treatment). Feces were collected and analyzed during the last three days of each experimental period. Urine, blood, and saliva samples were also collected for P measurement on the last day of each experimental period. True dP (dPDiet) was calculated using an indigestible marker (TiO_2) to estimate fecal output, and endogenous P losses were predicted from Meschy (2003). Phosphate dP (dPPi) was obtained by difference, assuming identical basal dPDiet as in the control treatment. The effect of Pi source was tested using a GLIMMIX procedure (SAS) and LSmeans were compared using the Tukey-Kramer method. The substantial differences in dPDiet and dPPi between treatments were not significant (Table 1) due to the high inter-individual variability. DCP increased urinary P concentration, suggesting a modification in P metabolism. Numerically, dPPi was lower with MCP, with no notable difference in the digestibility of the other components of the ration or in the P concentration in the matrices analyzed. The MagP treatment stood out with numerically higher digestibility of NDF (P=0.147, +3.1%, in MagP compared to other treatments) and crude protein (P=0.163, +2.3%), suggesting an overall improvement in digestive efficiency. For this treatment, as the metabolic parameters of P do not stand out particularly compared to the other treatments, the effect might originate from ruminal ecosystem. This work has drawn references value for dP from different Pi sources. Except for MCP whose low dPPi was not explained, the dPPi of other supplements were ranked as expected in the literature (Jongbloed et al., 2002). In this study, Pi source had limited impact on dPPi but the trends observed in the digestibility of other constituents and P metabolism deserve closer examination.

Table 1. Digestibility and metabolism of P depending on Pi source.

	DCP	MCP	MAP	MSP	MagP	SEM	Treatment effect P-value
Digestibility of P							
dPDiet (%)	67.5	61.9	67.8	68.9	68.2	2.8	0.168
dPPi (%)	43.3	9.0	48.4	50.4	45.4	17.2	0.214
dPPi (% dPDCP)	100	21	112	116	105		
P concentration in matrices (mmol/L)							
Blood	1.69	1.67	1.70	1.64	1.72	0.06	0.795
Saliva	6.71	7.33	6.94	6.79	6.23	0.85	0.793

Changes in rumen fermentation pattern with additional dietary potassium supply

Y. Zhang[1], H. Han[2], J. Guyader[3], S. Li[2]
[1] Evonik Co., Ltd, 19 Dongfang East Road,Chaoyang District, 100600 Beijing, China, [2] China Agricultural University, State Key Laboratory of Animal Nutrition and Feeding, College of Animal Science and Technology, 2 Yuanmingyuan West Road, 100193 Beijing, China, [3] Evonik Operations GmbH, 4 Rodenbacher Chaussee, 63457 Hanau, Germany

Dietary cation-anion difference (DCAD) is calculated as the difference in concentration between sodium and potassium (K) cations and chlorine and sulfur anions. The beneficial effect of increasing DCAD or the electrolyte balance (EB calculated as DCAD minus sulfur) of a diet on performance of lactating dairy cows has been reported in several meta-analyses, which all agreed that dry matter intake (DMI), milk production and fat-corrected milk (FCM) are maximized at an EB level between +350 and +550 mEq/kg DM. Behind this performance response, changes in rumen fermentation pattern are among the main mechanisms, though these effects have been less studied. Therefore, the objective of the present work was to assess the effect of an elevated dietary DCAD level through additional K on the rumen fermentation of lactating dairy cows. Thirty multiparous Holstein cows from a commercial herd in China were splitted into two homogeneous groups based on initial milk yield (38.8 ± 1.20 kg), days in milk (DIM: 126 ± 33 days) and body weight (BW: 600 ± 25 kg). For 84 days, cows were fed either a typical corn silage-based diet alone (Control; 16.2% CP, 28.4% NDF, and EB level of 355 mEq/kg) or supplemented with 250 g/d of potassium carbonate hydrate (PCH; K-pron®, Evonik, 56% K on a DM basis; EB level of 508 mEq/kg). Individual DMI and milk yield were recorded daily, whereas individual milk composition was tested every 2 weeks. Intake was measured with a Roughage Intake Control (RIC) system (Hokofarm, NL). After 0, 42 and 84 experimental days, blood and rumen samples were taken on 6 cows, 2h after feeding. Blood was taken from the tail vein and analyzed for K concentration. Rumen samples were taken by stomach tubing, and analyzed for pH as well as for K, ammonia (NH3) and volatile fatty acids (VFA) concentrations. Data were statistically analyzed with R software according to a linear model with the fixed effects of treatment, sampling time and their interaction. Significance was declared at $P < 0.05$. Increased levels of K were observed in the blood and milk of cows fed PCH, highlighting the high bioavailability of the tested potassium source. Cows fed PCH presented higher rumen pH compared to control cows (6.48 versus 6.39; $P = 0.002$). Ammonia and total VFA concentrations were not different between diets (9.14 mM and 109 mM, respectively), but changes in individual VFA proportion were noticed. Rumen acetate proportion was higher with PCH (51.2 versus 49.6%; $P = 0.012$) leading to a higher acetate to propionate ratio (1.66 versus 1.49; $P = 0.001$). These changes in rumen fermentation pattern, most likely related to the rumen buffering effect of PCH (carbonate fraction), must have triggered the higher milk fat percentage observed for cows fed PCH (4.06 versus 3.90%; $P = 0.002$). As a consequence, FCM also tended to increase with PCH (+1.5 kg/d; $P = 0.061$). Other performance-related parameters such as DMI, milk yield, milk protein or milk urea were similar between groups. In summary, this study linked the beneficial effect of increasing the dietary DCAD level on performance of lactating dairy cows, with changes in rumen fermentation pattern.

The effects of total dietary copper, sulfur, molybdenum, and Cu:Mo ratio on Cu status of sheep: A meta-analysis

J. A. Johnson[1], J. L. Ellis[2], G. B. Penner[1]
[1] University of Saskatchewan, Department of Animal and Poultry Science, 51 Campus Drive, S7N 5A8 Saskatoon, SK, Canada, [2] University of Guelph, Centre for Nutrition Modelling, Department of Animal Biosciences, 50 Stone Road East, N1G 2W1 Guelph, ON, Canada

Copper is an essential micronutrient for all ruminants, but sheep are especially susceptible to dietary imbalances due to poor metabolic regulatory mechanisms and antagonism between dietary Cu, S, and Mo which may reduce Cu absorption. Understanding what impacts plasma Cu concentration, the pool of Cu that is functionally available, may aid in developing nutritional management strategies. Therefore, a systematic literature review was conducted and data from 22 studies published between 1975 and January 2025 were compiled to evaluate the impact of varying dietary Cu, S, Mo, and the Cu:Mo ratio on plasma Cu concentration in sheep utilizing a meta-analytical approach. Data extracted from each publication included study design, study duration (d), number of experimental units including breed, sex, and age of sheep, dietary content of Cu, Mo, and S as well as form of Cu, Mo, and S when supplemented, end-of-study plasma Cu concentration, and end-of-study liver Cu concentration. Information on dry matter intake, average daily gain, and gain:feed were also extracted but due to a lack of reporting or incomplete information were not considered for use in modelling. All statistical procedures were conducted using SAS version 9.4 (SAS Institute Inc., Cary, NC). Prior to model development, the dependent variable (plasma Cu) was evaluated for normality using PROC UNIVARIATE. Mixed models were developed including the random effect of experiment with plasma Cu (mg/L) as the dependent variable. Fixed effects were evaluated for collinearity (and avoided), and effects were retained in models when $P \leq 0.05$. Independent variables assessed included the linear and quadratic effects of total dietary Cu and Mo (mg/kg DM), the Cu:Mo ratio (log transformed), total dietary S (% DM), end-of-study liver Cu (mg/kg DM), and study duration (d). Only independent variables with significance ($P \leq 0.05$) in univariable models were considered for inclusion in multivariable models. To account for heterogeneity in error and sample size across experiments, models were weighted by the inverse variance of the observation mean using the WEIGHT statement in PROC MIXED. Outliers were identified using the INFLUENCE option in PROC MIXED. Observations with a Cook's distance value greater than 4/n (where n = number of observations) were removed sequentially from the database. The final dataset included 22 experiments from 21 publications encompassing a total of 93 treatment mean observations. The final predictive models developed were evaluated using the developmental database. The model that best predicted plasma Cu included the quadratic effect of dietary Cu ($P = 0.044$), negative linear effect of dietary S ($P < 0.001$), and positive linear effect of dietary Mo ($P < 0.001$). The regression equation was expressed as: plasma Cu (mg/L) = 0.9761 (± 0.09280) + 0.0111 (± 0.00474) × Cu − 0.00012 (± 0.000056) × Cu^2 + 0.0055 (± 0.00110) × Mo − 0.6259 (± 0.17900) × S. This model demonstrated the best predictive performance with a concordance correlation coefficient (CCC) value of 0.835, a Pearson correlation coefficient (R) value of 0.850, and a root mean square prediction error (RMSPE) value of 14.11. No relation to study duration or liver Cu were observed ($P > 0.05$). Results support that dietary content of Cu, Mo, and S have significant influence on plasma Cu concentration of sheep. The positive effect of dietary Mo on plasma Cu concentration should be interpreted with caution as it does not indicate the form or availability of the Cu.

Influence of copper source on hepatic Cu accumulation, redox status and bile acid profiles in weanling and growing pigs

S. Cros[1], M. Fornòs[1], A. Monteiro[2], I. R. Ipharraguerre[3], G. Rimbach[3], H. H. Stein[4], J. F. Perez[1], D. Solà[1]
[1] Universitat Autònoma Barcelona, Animal Nutrition and Welfare Service (SNiBA), 08193 Bellaterra, Spain, [2] Animine, 10 Rue Léon Rey Grange, 74960 Annecy, France, [3] University of Kiel, Human Nutrition and Food Science, 24118 Kiel, Germany, [4] University of Illinois, Division of Nutritional Sciences, IL 61801 Urbana, United States

Copper (Cu) is an essential trace mineral involved in multiple physiological processes. Although pharmacological Cu supplementation improves growth performance in pigs, high dietary inclusion has been associated with excessive hepatic accumulation, oxidative stress and alterations in lipid and glucose metabolism (1). The present experiment was conducted to test the hypothesis that use of Cu2O rather than CuSO4 in diets for weanling and growing pigs favourably affects post-absorptive tissue Cu distribution, hepatic oxidative status, and bile acid (BA) metabolism. A total of 120 weaned pigs (7.13 ± 0.6 kg) were randomly allocated to 3 dietary treatments. The treatments consisted in a negative control diet (NC), formulated to provide 6-7 Cu mg/kg of Cu in accordance with NRC requirements (2012), and two diets supplemented with 250 mg/kg of Cu, provided either as CuSO4 or Cu2O. There was a total of 8 pens/treatment, with 5 pigs/pen. Body weight (BW) and feed intake were periodically recorded. On the last day of the experiment (Day 84), one pig per pen was euthanized to obtain liver, bile, and colon samples. Cu concentrations in liver and bile were quantified by ICP-MS. Hepatic oxidative status was assessed using the thiobarbituric acid reactive substances (TBARS) assay and glutathione (GSH) determination. BA profiles were analysed in bile, liver and colonic mucosa by HPLC-MS/MS. One-way ANOVA was used to determine the variance among treatments, followed by Tukey's post hoc test at a significance level of $P < 0.05$. Pigs from Cu supplemented groups showed higher BW at the end of the study ($P < 0.05$) and increased hepatic and biliary Cu concentrations ($P < 0.001$) compared with the NC. Cu hepatic accumulation was higher ($P < 0.05$) in the CuSO4 group. Hepatic GSH was increased ($P < 0.05$) in the Cu2O group but not in the CuSO4 group. TBARS did not significantly differ among groups ($P > 0.1$). Both Cu-supplemented groups had altered BA profiles relative to the NC. Lower ($P < 0.05$) concentrations of primary BA (CDCA and HCA) were observed in the colon and liver of the Cu2O group. The secondary BA (HDCA, LCA) were reduced in the colon ($P < 0.01$) in both Cu-supplemented groups compared with the NC. Performance results and liver Cu concentrations observed in this experiment are consistent with previous studies (2). The differences in hepatic Cu concentrations may be attributed to the greater solubility of CuSO4 relative to Cu2O, leading in a greater intestinal absorption and hepatic accumulation. Oxidative stress marker results suggest a more effective antioxidant response in the Cu2O group compared with CuSO4. The BA profile observed in Cu2O group suggests reduced hepatic BA synthesis. Although the underlying mechanisms of BA modulation remain unclear, the results point towards a potential involvement of the FXR receptor and increased ileal reabsorption, in response to altered signalling. In conclusion, dietary Cu supplementation at 250 mg/kg in diets for weaned and growing pigs influenced hepatic Cu metabolism, redox status, and BA metabolism. Compared with CuSO□, Cu□O resulted in less hepatic Cu accumulation and a more effective antioxidant response, together with changes suggestive of reduced hepatic BA synthesis at the same inclusion level. Genetics of traits derived from measures of milk electrical conductivity collected by milking robots and their correlations with clinical mastitis in Holstein cattle

J. M. Maskal[1], S. Y. Chen[1], L. F. Brito[1]
[1] Purdue University, Department of Animal Sciences, 270 South Russell Street, 47907 West Lafayette, United States

Genetic selection for mastitis resistance in dairy cattle has been conducted through both direct selection on clinical mastitis and indirect selection via correlated traits like SCS. Even with these efforts, mastitis remains a major concern for the dairy industry. Automatic milking systems collect measures of milk electrical conductivity (COND) for individual quarters of the udder at every milking visit, and traits derived from these measures may be good candidates for inclusion in selection indexes as indirect indicators of mastitis resistance. Therefore, the objectives of this study were to 1) derive multiple traits from quarter-level measures of milk COND collected by automatic milking systems; 2) estimate genetic parameters for traits derived from these measures; and 3) estimate (co)variance components between traits derived from measures of milk COND, health traits, and test-day traits in a population of American Holstein cattle. Quarter-level milk COND and visit milk yield were collected at every milking visit on 7,157 Holstein cows milked with automatic milking systems on a farm in north-central Indiana, USA. Additionally, producer-recorded events of clinical ketosis and clinical mastitis and test-day records of fat content, protein content, and SCS were available for an expanded population of cows that were milked in both automatic milking systems and conventional parlors. Eight traits were derived from quarter-level measures of milk COND collected at each milking visit. These visit-level traits were then summarized into daily values, either as the daily average or daily maximum, for subsequent analyses. Two additional traits were derived as the coefficient of variation or variance of all quarter-level measures of milk COND for an individual within a day. Additionally, data were analyzed separately by lactation: 1, 2, or 3+. Pedigree data for 53,186 individuals and genotype data for 29,126 individuals, imputed to 50,886 SNP, were used in the analyses. (Co)variance components were estimated using single-step GBLUP and linear animal models with REML. Estimates of heritability for traits derived from measures of milk COND ranged from 0.01±0.00 (range of COND scores; lactation 3+) to 0.52±0.01 (average of electrical COND; lactation 1). Estimates of genetic correlation between traits derived from measures of milk COND and clinical mastitis ranged from 0.27±0.09 (right-front COND score; lactation 3+) to 0.89±0.05 (coefficient of variation of COND scores; lactation 2), while estimates of genetic correlation between traits derived from measures of milk COND and SCS ranged from -0.05±0.09 (quarter extremes ratio of COND scores; lactation 1) to 0.76±0.03 (variance of COND scores; lactation 3+). Our results show that traits derived from measures of milk COND are heritable, and they have moderate to high genetic correlations with clinical mastitis, while having near-zero to high genetic correlations with SCS. These results suggest that traits derived from measures of milk COND are promising indicators of clinical mastitis and incorporating them into selection indexes in complement to traits already included in indexes for udder health can enhance genetic selection for mastitis resistance.

Personality-informed genomic prediction of sensor-derived feeding behaviour and resilience traits in dairy cows

A. Seidel[1], P. Hasenpusch[1], T. Wilder[1], G. Thaller[1]
[1] Kiel University, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany

Large amounts of data from automated feeding systems enable the derivation of novel phenotypes capturing feeding behaviour and resilience in dairy cattle. In addition to environmental and physiological drivers, stable individual differences in personality may influence how cows interact with feeding resources, potentially leading to consistent differences in feeding behaviour and resilience. Therefore, this study aimed to (i) derive feeding behaviour and resilience traits from automated feeding records, (ii) estimate genomic parameters, and (iii) evaluate whether personality information improves their genomic prediction. Daily records from an automated feeding system (155,843 cow-days) were quality-controlled and restricted to days in milk (DIM) 5–400. Implausible observations were set to missing on a variable-specific basis, and short data gaps were interpolated within cow and lactation. Feeding behaviour traits were defined as feed intake per visit (IPV) and the proportion of unsuccessful visits (UVR). Resilience was quantified as the log-transformed variance of deviations from generalized additive model (GAM)–derived lactation trajectories (y ~ s(DIM)) for milk yield, dry matter intake, and UVR. Personality was assessed using standardized behavioural tests, including novel object and forced human approach tests. Responses were pre-adjusted for environmental effects and summarized into four personality dimensions using principal component analysis. The final dataset comprised 597 lactations from 263 cows with complete phenotype, personality, and genotype information. To improve the stability of individual-level estimates, cow-level phenotypes were derived as the median across available lactations. Additionally, personality traits were reduced to the first principal component (PC1; 30.1% variance explained), providing a composite personality descriptor. To estimate genomic parameters, a genomic relationship matrix based on 45,613 markers was used in genomic mixed models, with mean parity per cow included as a covariate to account for differences in lactation structure and information content. Genomic prediction was evaluated using repeated five-fold cross-validation with GBLUP. For this analysis, three representative traits were selected to illustrate prediction performance, and the potential contribution of personality information was assessed through changes in test-set RMSE and R^2. Sensor-derived feeding behaviour and resilience traits showed moderate to high genomic heritabilities (±SE), including IPV (0.68 ± 0.09), dry matter intake resilience (0.52 ± 0.10), UVR resilience (0.64 ± 0.09), milk yield resilience (0.42 ± 0.10), and mean UVR (0.32 ± 0.11). Genomic prediction accuracies, expressed as correlations between predicted and observed phenotypes, were 0.36, 0.38, and 0.48 for intake resilience, UVR resilience, and IPV, respectively. However, including personality PC1 did not improve prediction performance ($\Delta RMSE \approx 0$; $\Delta R^2 \approx 0$). Overall, automated feeding system data enable the derivation of biologically interpretable feeding behaviour and resilience phenotypes with measurable genomic signals. Within the present dataset, personality information did not provide additional predictive value beyond genomic relationships. Larger datasets and alternative modelling strategies, including models explicitly accounting for repeated lactations (e.g. repeatability or random regression models) or alternative personality indices, may help to further evaluate the potential role of personality in genomic prediction of feeding behaviour and resilience traits.

Genetic parameters of rumination and eating behaviour in Holstein cows monitored using collar-based precision livestock farming sensors

V. Brajkovic[1], M. Oroz[2], M. Oroz[2], N. Raguz[2], I. Drzaic[1], M. Shihabi[1], M. Špehar[3], T. Bobic[2], I. Curik[1], B. Lukic[2]
[1] University of Zagreb Faculty of Agriculture, Department of Animal Science, Svetosimunska cesta 25, 10000 Zagreb, Croatia, [2] JJ Strossmayer University of Osijek Faculty of Agrobiotechnical Sciences, Department for Animal Production and Biotechnology, Vladimira Preloga 1, 31000 Osijek, Croatia, [3] Croatian Agency for Agriculture and Food, Gorice 68B, 10000 Zagreb, Croatia

Precision livestock farming (PLF) technologies enable continuous monitoring of behavioural traits that may serve as indicators of animal welfare, productivity and environmental adaptation. The aim of this study was to evaluate feeding behaviour traits recorded by collar-based sensors and to estimate their genetic parameters in dairy cattle. Behavioural data were collected using Aficollar (AfiAct II) sensors on three commercial Holstein farms located in Osijek–Baranja County, Croatia. After data editing, 26,462 daily behavioural records from 454 cows (n = 171, n = 147 and n = 136 across farms) were available for analysis. Recording periods differed among farms and ranged from May 2025 to January 2026. Mean rumination and eating times were 491 and 325 minutes per day, respectively. Environmental conditions varied substantially across farms, with temperature–humidity index (THI) values ranging from 37.9 to 84.4, representing winter conditions to summer heat stress. Correlation analysis showed a positive relationship between rumination and eating time, while both behavioural traits were negatively associated with THI, indicating reduced feeding behaviour under heat stress. Mixed model analysis further confirmed this pattern, with both rumination and eating time decreasing by approximately 2.2 minutes per unit increase in THI. Genetic parameters were estimated using pedigree-based repeatability animal models including fixed effects of farm, parity, days in milk and THI, and random effects of animal additive genetic and permanent environmental effects. Heritability estimates were low for rumination time ($h^2 = 0.04$) and moderate for eating time ($h^2 = 0.24$). Repeatability estimates were moderate for both traits (0.52–0.55), indicating consistent behavioural differences among cows. These preliminary results demonstrate that collar-derived behavioural traits capture meaningful biological variation and that eating behaviour shows moderate genetic variability, suggesting potential for inclusion of such traits in future breeding and management strategies. Ongoing genomic analyses will further support the investigation of genetic architecture underlying behavioural responses recorded through PLF technologies.

Big Data Meets Behavior: Genetic Characterization of AMS-Based Indicators in Dairy Cows

J. Stuhlträger[1], F. Rosner[1], S. König[2], L. Behren[2], L. Breitmeier[2], H. H. Swalve[1]
[1] Martin-Luther-University Halle-Wittenberg, Institute of Agricultural and Nutritional Sciences, Theodor-Lieser-Str. 11, 06120 Halle, Germany, [2] Justus-Liebig-University, Institute of Animal Breeding and Genetics, Ludwigstr. 21, 35390 Gießen, Germany

Automated milking systems (AMS) continuously gain importance in dairy cattle herds which is mostly triggered by an increasing shortage of qualified labor. For AMS with free cow traffic, the behavior of cows to adapt to such systems is of high relevance and partly is determined by genetic effects. Apart from behavioral categories such as fear or aggressiveness, cows also need to learn that robot systems are programmed such that milking intervals cannot be too short as this would hamper the effectiveness of the AMS. AMS provide a number of parameters related to behavioral traits. Traits related to milking temperament will be udder scan time (UST) or connecting time (CT) while repeated short visiting intervals (VI) and a resulting high number of rejected milkings (RM) can be attributed to learning behavior. Aim of the present study was to define parameters from UST, CT, VI and RM and subsequently estimate genetic parameters as well as conduct a GWAS to unravel genomic regions of interest. Data was collected from 24 German dairy farms and covered a time span from 2007 – 2024. Data comprised 15,684 Holstein cows with 41,581 lactations and was aggregated on a daily basis to form 12,186,928 daily cow-AMS interactions. SNP genotypes were supplied by Vereinigte Informationssysteme Tierhaltung w.V. (VIT), Verden, and consisted of 10-K genotypes imputed to 50 K with 45,613 usable SNP. All cows were genotyped and phenotyped. For the estimation of genetic parameters under ssGBLUP, the BLUPF90 software was used. Heritability estimates were 0.1 (SE = 0.005) for RM and 0.25 (SE = 0.007) for VI, respectively, with a highly negative genetic correlation (-0.98) between them. Both traits are highly influenced by the ability of the cow to adapt to the time limits set for subsequent milkings and thus strongly determined by learning behavior. Furthermore, GWAS for the trait RM revealed a number of interesting regions on chromosomes 14 and 29 with several genes well known from model animal or human genomics. The traits UST and CT, which could be taken as indicators for AMS effectiveness exhibited lower heritabilities, ranging from 0.04 (SE =0.003) to 0.07 (SE =0.005), respectively. UST and CT had a positive genetic correlation of 0.76. GWAS for UST and CT revealed interesting regions on chromosome 8 and 26 with some genes related to fear behavior or stress.

Genetic parameters of feeder replacement traits from electronic feeders' records in cattle

J. D. P. S. Valente[2], L. F. M. Mota[2], G. R. D. Rodrigues[2], T. L. S. Soares[2], J. A. Silva[2], K. D. S. Pinto[2], L. F. C. Araujo[1], R. C. Canesin[1], S. F. M. Bonilha[1], J. N. S. G. Cyrillo[1], M. E. Z. Mercadante[1]

[1] Institute of Animal Science, Beef Cattle Research Center, Rod. Carlos Tonani, km 94, 14160-900 Sertãozinho, Brazil, [2] São Paulo State University, School of Agricultural and Veterinary Sciences, Via de Acesso Professor Paulo Donato Castelane Castellane, 14884-900 Jaboticabal, Brazil

Feeder replacements, defined as the rapid succession of two different animals at the same feeder, can indicate competition for access to feed in group-housed cattle. However, replacement detection from electronic feeders depends on the time interval between consecutive visits: short windows (<20 – 30 s) are more likely to reflect competitive displacements, whereas longer windows increasingly mix competitive and non-competitive successions. We therefore aimed to derive feeder replacement traits from electronic feeder records in Nellore cattle, quantify the impact of replacement windows on trait distributions, estimate genetic parameters, and test social genetic effects. Electronic feeder data (Vytelle SENSE) were collected in feed efficiency trials from 1368 young male Nellore cattle (three selection lines; born from 2013 to 2024; 32 pens). To standardize exposure, records were restricted to the first 70 days on trial, and animals with <39 valid days were removed, resulting in 1363 animals and 7,462,183 cleaned feeder visits (85.5% of the original records). For each feeder within the pen, visits were ordered chronologically, and the next visit at the same feeder was identified; the second animal was defined as the follower. After discarding sequences with the same animal as follower or missing follower identification, 7,312,133 visits remained to compute 2 traits per animal across five-time windows (≤5, ≤10, ≤20, ≤30, ≤300 s): average daily replacement frequency (Rd5 – Rd300) and the logit-transformed proportion of visits as follower (LPR5 – LPR300). Outliers (mean ± 3.5 SD within contemporary group) were set to missing. Genetic parameters were estimated via ssGBLUP using a relationship matrix combining pedigree (5,068 animals) and genomics (3,860 animals; 383,343 autosomal SNPs). Fixed effects included contemporary group (birth year × pen) and line, with covariates for animal age at beginning of the trial and dam age at calving; total feeder visits (Rd traits) or valid days on trial (LPR traits) were additionally fitted. A social animal model was fitted for LPR traits to partition direct and social additive genetic effects. Replacement events followed the daily feeder-use pattern, peaking after fresh feed delivery. The mean follower proportion increased from 35.5% (≤ 5-s) to 94.9% (≤ 300-s), consistent with broader windows capturing near-continuous feeder usage. Heritability for Rd traits was low to moderate and window-dependent (Rd5 = 0.33 ± 0.05; Rd10 = 0.36 ± 0.05; Rd20 = 0.33 ± 0.05; Rd30 = 0.30 ± 0.05; Rd300 = 0.14 ± 0.05). LPR traits were consistently moderately heritable (LPR5 = 0.40 ± 0.05; LPR10 = 0.46 ± 0.05; LPR20 = 0.44 ± 0.05; LPR30 = 0.44 ± 0.05; LPR300 = 0.40 ± 0.05), with the highest estimate at ≤ 10-s. Genetic correlations were positive and strongest among adjacent windows (up to 0.98), but weakened when the 300-s window was involved (rg = 0.39 – 0.86). Social additive genetic variance for LPR traits was near zero (≤ 3×10□□) and did not improve model fit. Feeder replacement traits are heritable, scalable behavioral phenotypes in Nellore cattle, and the replacement window affects both trait meaning and genetic inference. In this dataset, 10-s window maximized heritability. These phenotypes can be extracted routinely on a scale from electronic feeders data. Study supported by FAPESP Process #2026/07564-7.

Relationship between daily milking records and health status of dairy cows

E. Kašná[1], L. Zavadilová[1], Z. Krupová[1]
[1] Institute of Animal Science, Genetics and Breeding of Farm Animals, Přátelství 815, 10400 Prague, Czech Republic

Indicators derived from records generated by automated milking systems (AMS) are used for early indication of a health status of dairy cows. They can also be used to define new phenotypes for breeding a resilient and sustainable dairy population. Our aim was to evaluate several potential indicators based on AMS records and their relationship to the occurrence of common cattle diseases. The initial dataset contained more than 1.6 million records of 1,613 cows collected from March 2023 to December 2025 on three farms equipped with DeLaval AMS. Potential indicators included daily milk yield (DMY; mean = 33.2 kg per day), number of milkings (NM; 2.5 milkings per day), mean (ECmean; 4.6 mS/cm) and maximum (ECmax; 4.9 mS/cm) electrical conductivity (EC) of milk and natural log-transformed inter-quarter range (lnIQR = ln(ECmax/ECmin); 0.1). Pearson correlation coefficients showed a strong relationship between ECmean and ECmax (0.83), between DMY and NM (0.65) and between ECmax and lnIQR (0.63). The relationships between lnIQR and other traits were weak and negative (-0.15 with DMY, -0.11 with NM). The data were supplemented with records of mastitis (MAS; n = 682), reproductive disorders (REP; n = 286), hoof and leg disorders (HL; n = 374) and metabolic diseases (METAB; n = 149) occurrence. We used the GLM procedure (SAS 9.4; SAS Institute, Cary NC) to assess the impact of fixed effects on the variability indicators. The indicators differed significantly across farms (3 levels), years (3 levels; 1. 2023, 2. 2024 and 3. 2025) and seasons of milking (4 levels; 1. March–May, 2. June–August, 3. September–November, 4. December–February), parities of cows (3 levels; 1st, 2nd, 3rd and subsequent parities), breeds of cows (3 levels; 1. Czech Simmental, 2. Holstein, 3. crossbreeds) and lactation stages based on days in milk DIM (3 levels; 1. DIM0-100, 2. DIM101-200, 3. DIM201-305). We used the GLIMMIX procedure with a logit link (SAS 9.4) to evaluate the impact of selected indicators, fixed effects, and the random effect of cows on health status. The results showed a close relationship between health status and data obtained during robotic milking. Lower DMY was associated with an increased likelihood of disease occurrence, as expressed by estimated odds ratios (OR) and 95% Wald confidence limits (Cl) for MAS (OR = 0.92; Cl 0.91–0.92), REP (OR = 0.94; Cl 0.93–0.95), HL (OR = 0.96; Cl 0.95–0.97), and METAB (OR = 0.89; Cl 0.88–0.90). A decrease in milk production is one of the first signs of disturbed homeostasis, negative energy balance, or systemic inflammatory response. It may reflect both the direct impact of the disease on metabolism and feed intake, as well as changes in animal behaviour, such as reduced activity. An increased EC was associated with a higher probability of MAS with corresponding ECmean (OR = 4.31; Cl 3.88–4.79) and ECmax (OR = 2.8; Cl 2.70–2.95) values. LnIQR showed a very strong association with MAS, but the odds ratio was unstable (OR>999.99). LnIQR also showed associations with REP (OR = 11.73; Cl 2.72–50.65), HL (OR = 7.73; Cl 2.32–25.07) and METAB (OR = 22.06; Cl 4.15–117.37). Increased conductivity is a known consequence of inflammatory processes in the mammary gland, characterised by changes in epithelial permeability and increased ion penetration into milk. Uneven conductivity between quarters may reflect local pathological processes or subclinical inflammation, which can be a source of systemic stress and, secondarily, affect other physiological functions and health status of the animal. Supported by the Ministry of Agriculture of the Czech Republic, project QK24020269 and institutional support MZE-RO0723-V02.

ICAR/IDF Sensor Initiative: Guidelines and reference standards for using rumination sensor data in animal health and welfare - recommendations for sensor data use for genetic evaluation

The use of on-farm sensor systems is generating an ever-increasing volume of detailed data. These data can support genetic evaluation as novel auxiliary traits and enable improvement of animal health and welfare, while strengthening transparency and sustainability in the dairy sector. The joint ICAR/IDF Sensor Initiative aims to develop harmonised guidelines to facilitate the effective use of sensor-derived data to improve animal health and welfare. Bringing together experts from the ICAR Functional Traits Working Group and the IDF Standing Committee on Animal Health and Welfare, the initiative represents key stakeholders from academia, breeding organisations, and the dairy industry. The main objectives of this effort are to develop and reach consensus on: standardised definitions, data editing, and terminology for health conditions and behavioural traits measured with sensor systems; data exchange standards that support interoperability along the dairy value chain and are aligned with recognised ICAR and IDF principles; best prediction guidelines for data collection, processing and analysis to support genetic evaluations, management practices and health and welfare assessments; and, validation protocols for evaluating sensor performance. This platform enables discussion of results, refinement of proposals and alignment with the needs of stakeholders. The initial outcomes of the rumination sensor use case include recommendations for integrating rumination data into genetic evaluations and breeding programmes, developing auxiliary and key indicator traits, and establishing reference standards for resilience, health, and welfare assessment in dairy cattle. Scientific background papers on the application of sensor data in genetics and breeding, as well as guidelines for data cleaning, have already been published. Close collaboration between stakeholder groups within the ICAR/IDF initiative supports the strategic goals of both organisations by promoting widely accepted, science-based guidelines that benefit the entire dairy value chain. This presentation will provide an overview of the detailed recommendations, focusing on those related to data and information requirements for the use of sensor data in genetics.

Three-dimensional imaging provides scalable body weight phenotypes for management and breeding in dairy cattle

C. Bengtsson[2], K. Kupisiewicz[1], R. Bak Stephansen[3], J. Lassen[1,3]
[1] VikingGenetics, R&D, Ebeltoftvej 16, 8960 Randers, Denmark, [2] VikingGenetics, R&D, Järnvägsgatan 20, 53239 Skara, Sweden, [3] Aarhus University, Center for Quantitative Genetics and Genomics, C. F. Møllers Allé 3, 8000 Aarhus C, Denmark

Precision livestock farming technologies enable large-scale phenotyping under commercial conditions. Body weight (BW) and BW change across lactation are biologically relevant indicators of maintenance requirement and energy balance but are rarely recorded frequently enough in commercial herds to support routine decision-making and genetic evaluation. Three-dimensional (3D) imaging systems allow BW to be estimated automatically, non-invasively, and repeatedly under commercial conditions. The objective of this study was to evaluate scalable BW phenotypes derived from the CowFIT 3D camera system (VikingGenetics, Randers, Denmark) for use in herd management and genetic evaluation in Nordic Holstein, Jersey, and Red Dairy Cattle. Body weight was predicted from dorsal 3D images collected automatically in commercial Danish dairy herds. A total of 11,047 complete lactations recorded between 2019 and 2025 in Nordic Holstein, Red Dairy Cattle, and Jersey cows were analysed. Across lactations, average BW ranged from approximately 436 kg in primiparous Jersey cows to 740 kg in multiparous Holstein cows. Individual BW trajectories were used to derive BW level and early- and late-lactation BW change. Genetic parameters were estimated using bivariate animal models. Predicted BW during the final week before slaughter showed strong phenotypic correlations with slaughterhouse-recorded live and carcass weights ($r \geq 0.89$), supporting the plausibility of routinely collected 3D-derived BW under commercial conditions. Body weight level traits were moderately to highly heritable (0.40 – 0.63; SE = 0.03 – 0.04), whereas BW change traits showed lower heritability (0.13 – 0.19; SE = 0.03 – 0.04) as expected. On average, primiparous cows lost approximately 23 kg BW, whereas multiparous cows lost up to 60 kg from calving to minimum BW. Cows predisposed to greater BW loss after calving also tended to regain more BW later in lactation. Body weight change traits showed negative genetic correlations with milk yield (r_g = -0.30 to -0.18), whereas phenotypic correlations followed the same pattern but were weaker in magnitude. Greater BW at primiparous calving was associated with higher milk yield, but this relationship diminished in later lactations. In contrast, average BW showed weak or slightly unfavourable relationships with milk yield, particularly at the genetic level in later lactations. These results demonstrate how scalable 3D-derived BW phenotypes can be used to characterize size and energy dynamics, with potential applications in genetic evaluation and herd-level management through improved monitoring of BW development and energy balance across lactation in commercial dairy systems. While BW level traits largely reflect maintenance requirements commonly accounted for in feed-efficiency evaluations, BW change traits may provide additional information on metabolic resilience.

Grazing traceability of dairy cows with GPS and accelerometer sensors.

C. Allain[1], A. Delpeuch[2], M. Vimont[3], M. Legris[3]
[1] Institut de l'élevage, 8 route de Monvoisin, 35650 Le Rheu, France, [2] Institut de l'élevage, Boulevard des arcades, 87000 Limoges, France, [3] Institut de l'élevage, 149 rue de Bercy, 75012 Paris, France

In France, dairy farms producing milk for specific quality schemes such as Protected Designation of Origin (PDO) cheeses and organic milk must comply with strict grazing specifications, including a minimum grazing duration (generally ≥170 days per year with ≥6 hours per day) and a minimum grazing area (≥30 ares per cow per year). Compliance is currently verified through periodic on-farm audits based on visual observations, paper grazing records and farmer declarations. These procedures are time-consuming and lack precision. Digital technologies, including Global Positioning System (GPS) and accelerometer sensors combined with advanced data analysis, offer new opportunities to automate and objectify grazing traceability. This study evaluated the potential of GPS and accelerometer sensors to assess grazing time and pasture use in five dairy farms located in the Maroilles PDO cheese area (France). During the grazing season, one or two cows per farm were equipped with two types of collars: (i) a GPS collar (RF Track) recording positions every 15 minutes, and (ii) a high-frequency GPS/accelerometer collar (Tauro, Embeint) recording positions every second with high spatial accuracy. The objectives were: (1) to quantify outdoor time, paddock use and effective grazing time; (2) to generate relevant indicators for grassland management; and (3) to evaluate the added value of high-frequency positioning and behavioural data compared with standard GPS monitoring. As a first step, high-frequency GPS data were used as a reference to classify cow location (barn vs pasture), complemented by farmer declarations. Density-based clustering methods were applied to 15-minute GPS data to automatically detect barn areas and estimate time spent outdoors. Across farms, mean daily outdoor time during the grazing season ranged from 7 to 20 hours, highlighting substantial variability in grazing practices within the same production area. Spatial overlap between GPS positions and paddock boundaries enabled the estimation of time spent in each paddock, allowing both the reconstruction of grazing calendars and the calculation of daily grazed surface per herd. As a second step, high-frequency GPS and accelerometer data were analysed to assess their added value. Behavioural classification based on movement and activity signals allowed discrimination between grazing and non-grazing activities while outdoors. This approach enabled estimation of effective grazing time, identification of under-utilised areas and refinement of paddock-level utilisation indicators. Compared to low-frequency GPS alone, the combined high-resolution positioning and behavioural data improved the accuracy and robustness of grazing traceability metrics. These results demonstrate that embedded sensor technologies, combined with adapted data processing methods, can provide reliable and automated tools for grazing traceability in quality-labelled dairy systems. Beyond compliance monitoring, such systems offer additional decision-support indicators for farmers and advisers to improve grassland management.

Effect of eating dynamics on enteric gas concentration recorded via sniffer in dairy cows

G. Giagnoni[1], M. Bjerring[1], V. Milkevych[2], T. M. Villumsen[2]
[1] Aarhus University, Department of Animal and Veterinary science, Blichers Alle 20, 8830 Tjele, Denmark, [2] Aarhus University, Center of Quantitative Genetics and Genomics, C.F. Møllers Alle 3, 8000 Aarhus, Denmark

Enteric CH4 emission is affected by the diurnal pattern of eating dynamics. The aim of this study was to assess the effect of a cow's visit to the main feed on the gas concentrations measured by a sniffer instrument. Lactating Danish Holstein cows were housed in a loose pen with mats and slatted floors. The cows had access to a partial mixed ration fed in automatic feeding bins (AFB) which recorded individual feed intake. In addition, cows had access to an automatic concentrate feeder (ACF), which was fitted with a CH4 sniffer with Guardian hardware (Edinburgh Instruments, Livingston, UK). Data from three months, December to February, of recording was available from the Danish Cattle Centre, AU Viborg, Denmark. Cow's visits had to meet these conditions: 1) had sniffer visits with at least two minutes of gas recording, 2) had visited both AFB and sniffer on the same day, 3) had a minimum of three meals per day from the AFB, and 4) had at least 14 days with valid data. A visit to a feeder was considered as a meal if there was a minimum of 30 min break between the two consecutive visits to the same type of feeder. The sniffer-recorded gas concentrations were processed using the GEDA software to ensure a high quality data. Finally, AFB and ACF data were merged in chronological order, and time distance (TD) as min between a sniffer visit and the last meal at the AFB were calculated. In some instances, a visit to the ACF happened during a meal at the AFB, in which case the TD was considered 0. If a cows visited the AFB before going to the ACF, the feed intake as kg fresh matter, approximately 40% DM, from the AFB was associated with the visit to the sniffer, and defined as last feed intake before gas measurement (LF). The data was analysed with a generalized mixed linear model with CH4 (ppm), CO2 (ppm) or CH4:CO2 ratio as dependent variable using a Gamma distribution with log link. The explanatory variable of the model included a mean intercept, the regression coefficients for centred TD, centred LF, the interaction between the two, and the squared LF, as fixed effects. The random effects included the regression coefficients for centred TD and LF within cow, and the random intercepts for cow and date. The CV for the residuals was calculated as a percentage of the ratio between the SD of the residuals and the average of the observed variable. Data from 34 cows was retained, with an average of 32.8 ± 11.8 day per cow (14 – 61 d, min – max). The concentration of CH4 was affected by TD and LF ($p = 0.04$ and $p = 0.01$). Increasing TD and LF increased CH4 concentration with 0.29 10^{-3} ppm/min for TF, and 0.68 10^{-3} ppm/kg for LF. Similarly, the concentration of CO2 was affected by TD and LF ($p < 0.001$ and $p = 0.01$). Both increasing CH4 concentration with 0.50 10^{-3} ppm/min for TF, and with 6.1 10^{-3} ppm/kg for LF. The CH4:CO2 ratio decreased with increasing TD ($p < 0.003$, −0.24 10^{-3} ppm/min). The effect of LF was not significant, but it tended to increase the CH4:CO2 ratio ($p = 0.07$). The CV for the residuals on the mean were 51, 38, 32% for CH4, CO2, and CH4:CO2. This study indicates that eating dynamics affects gases concentrations measured from sniffer. However, the eating dynamics and random effect of date and individual cow left up to 50% of the gas concentration unexplained. Using the CH4:CO2 reduced the residuals error.

Non-invasive infrared measurement of exhaled methane in dairy cows based on spot sampling during automatic milking

F. Neubert[1,2], A. M. Scholz[2], A. K. Calliotte[1,2], C. Schmidt[1], P. V. Kremer-Rücker[1]
[1] Weihenstephan-Triesdorf University of Applied Sciences, Faculty of Agriculture, Food and Nutrition, Markgrafenstr. 16, 91746 Weidenbach-Triesdorf, Germany, [2] Livestock Center Oberschleissheim, University of Munich (LMU), Veterinary Faculty, St.-Hubertusstr. 12, 85764 Oberschleissheim, Germany

Ruminants are essential to sustainable agriculture by converting human-indigestible plant biomass into high-quality animal protein, yet their enteric methane emissions substantially contribute to the sector's climate impact. Robust and practical measurement technologies are needed to support mitigation strategies under commercial conditions. This study evaluated the effectiveness of a non-invasive methane sensing approach based on spot sampling, which was integrated into an automatic milking system for German Holstein, Fleckvieh, and crossbred dairy cows. Between April and December 2025, breath samples were continuously drawn via a small sampling probe during milking and analysed in real time using infrared detection (IRD). Methane prediction values obtained from routine milk recording provided by the Bavarian State Association for Animal Production (Landeskuratorium der Erzeugerringe für tierische Veredelung in Bayern e.V.; LKV) were used as the reference standard. A total of 425 observations from 148 cows recorded on six performance test dates were analysed. Prior to regression analysis, a mixed model analysis was performed using SAS 9.4, including the random effects cow and test date, as well as the fixed effects genetic group and the covariables days in milk, energy corrected milk, IRD minimum (IRD-Min) and IRD maximum (IRD-Max). In addition, stepwise regression analysis using the same variables (excluding the fixed and random effects) confirmed that all the predictors were significant contributors to the model, yielding an R2=0.56 [root mean square error (RMSE) 39.6 l/d]. After applying a breed-specific correction factor, the coefficient of determination improved to R2=0.59 (RMSE = 30.3 l/d). LKV-derived methane estimates showed a relatively high association with the predictors derived from the mixed model analysis containing the infrared-based methane measurements (IRD-Min, IRD-Max) as co-variables (R2=0.64, RMSE 35.4 l/d) – demonstrating substantial predictive capacity despite on-farm variability. These findings provide compelling evidence that infrared-based, non-invasive breath analysis during milking could become a robust and scalable method for quantifying enteric methane emissions in dairy cows and holds promise for integration into large-scale monitoring and mitigation frameworks.

Broader potential applications of sniffer systems: A pilot study of installation on automatic feeder station

C. Rossi[1], G. Grossi[1], N. Lacetera[1], A. Vitali[1]
[1] University of Tuscia, Department of Agriculture and Forestry Sciences, via San Camillo De Lellis snc, 01100 Viterbo, Italy

The implementation of sniffer systems for monitoring enteric emissions is supporting genetic improvement programmes for the selection of low-emitting animals within the context of global greenhouse gas mitigation strategies. Over recent years, trials involving sniffers have commonly been associated with the presence of automatic milking systems (AMS), facilitating the collection of emissions data in dairy production systems; however, limiting their application to farms with AMS. Automatic feeder stations (AFS) equipped with individual animal identification systems and structural containment can also be suitable for sniffer installation, as they recognize and maintain the animal isolated for defined periods during the day. Nevertheless, animals' use of AFS differs from the use of AMS in terms of visit duration and daily frequency; for this reason, appropriate sniffer data management strategies need to consider these conditions. This research aims to provide a pilot trial of enteric emission monitoring using a sniffer installed on an AFS and to compare the monitored emission levels to those estimated using the IPCC Tier 2 equations. The trial was conducted on a dairy farm rearing Holstein-Friesian and Pezzata Rossa cows, where a sniffer (MooLogger, Tecnosens IT) was installed on an AFS (DairyFeed C8000, GEA DE). Data on emissions, individual production and physiological state were gathered from 70 lactating animals between July 2025 and January 2026. The mean duration of animal visits to the AFS was 00:01:25, with an average frequency of 5.5±3.5 visits/head/day. Visits lasting less than one minute were discarded, as they were not consistent for evaluating CH4 and CO2 patterns. Sniffer data were aligned with AFS recordings using timestamps, and gas measurements were processed by removing outliers, negative values, and background gases. To detect eructation events, CH4 peaks were identified, showing an average of 1.43 ±0.70 peaks per visit. Visits with at least one peak were selected and CH4 emissions as grams per day were calculated through the CH4-to-CO2 ratio. Preliminary results indicate an 11% discrepancy between emission levels detected using the sniffer and those estimated with the IPCC Tier 2 equation. Mean CH4 emissions calculated from sniffer data were 349.8 ± 177.6 g/head/day, referring to a CH4-to-CO2 ratio of 0.09±0.04, whereas emissions estimated using the Tier 2 equation averaged 387.1 g CH4/day. Further research is needed to confirm these results, and different approaches can be explored to improve the quantification of CH4 emissions from AFS visits using sniffer data. The use of sniffer systems on AFS could represent a promising step toward enhancing in-vivo monitoring of enteric emissions in ruminant production systems, broadening the range of dairy farms that can participate in monitoring programmes and extending this capability to beef systems.

Proxies for early lactation ketosis in Austrian Fleckvieh dairy cattle based on daily milk yield and rumination data

K. Schodl[1], B. Fuerst-Waltl[2], F. Steininger[1], C. Egger-Danner[1]
[1] ZuchtData EDV-Dienstleistungen GmbH, Dresdner Str. 89, 1200 Vienna, Austria, [2] BOKU University, Institute of Livestock Sciences, Gregor-Mendel-Str. 33, 1180 Vienna, Austria

As the use of automatic milking systems (AMS) and sensor systems for herd management increases, the potential use of data from these systems for breeding purposes is being investigated more and more. There is particular interest in the potential to derive phenotypes that can be used as proxies for traits with low heritability and/or costly phenotyping. Due to the low frequency of diseases, functional traits related to dairy cow health are the perfect example of traits with low heritability and challenging phenotyping. In this study, we investigated the potential of using traits derived from daily milk yields and daily rumination time data to predict early lactation ketosis in Austrian Fleckvieh dairy cows. AMS data were available for 5,436 cows from 66 commercial dairy farms, 25 (1,727 cows) of which were also equipped with Lely sensor systems. Results from blood tests measuring β-hydroxybutyrate (BHB) levels were used as a reference for ketosis (available for 68 farms and 3,359 cows). In addition to BHB concentrations in mmol/L, a binary coding approach was applied to the ketosis level trait: concentrations exceeding 1.2 mmol/L indicated a state of (subclinical) ketosis (1), while concentrations below this threshold indicated a healthy state (0). As rumination curves resemble lactation curves, we investigated the potential of Wood function parameters and individual deviations from it to define auxiliary traits for early lactation ketosis using milk yield (MY) and rumination time (RT) data. First, we estimated the single parameter b, representing the ascending slope in the Wood function, for MY and RT for each cow within the first 30 days of milk production and calculated the ratio between these two. Additionally, Wood curves were fitted for all animals in parity 1 and for animals in higher parities, respectively, in a mixed model approach including animal (and lactation for animals in higher parities) as random effect and a correcting for autocorrelation of repeated measurements within the same lactation. The traits based on the residuals of each animal were defined as follows: the sum of the daily residuals divided by the number of days, and the ratio between the rumination and milk residual traits. Heritabilities were 0.18 (±0.03) for BHB blood levels and 0.12 (±0.03) for the binary ketosis trait, 0.09 (±0.02) for bMY and not significantly different from 0 for bRT. Due to the high genetic correlation between the two traits (-0.78 ±0.28), estimates for the ratio between them were not considered reliable. A negative genetic correlation was found between bMY and blood BHB level (-0.62 ±0.17). Based on this high genetic correlation and the presence of AMS on many dairy farms this trait may be considered as potential auxiliary trait for ketosis. Further results and genetic correlations with other traits in the total merit index will evaluate the suitability for routine genetic evaluation for metabolic stability in dairy cows.

AI-based 3D monitoring of behavior and welfare indicators in cows during the preclinical phase of atypical BSE

S. Jahn[1], S. Ernst[2], C. Fast[2], T. Homeier-Bachmann[1]
[1] Friedrich-Loeffler-Institut, Institute of Epidemiology, Südufer 10, 17493 Greifswald - Insel Riems, Germany, [2] Friedrich-Loeffler-Institut, Institute of Novel and Emerging Infectious Diseases, Südufer 10, 17493 Greifswald - Insel Riems, Germany

Atypical bovine spongiform encephalopathy (BSE), also known as “mad cow disease”, continues to challenge animal health, food safety, and fundamental research. In an ongoing experiment investigating the pathogenesis of atypical BSE, 20 young cows were infected with either H- or L-type atypical BSE by intracerebral inoculation. The clinical onset of the disease, characterized by typical neurological symptoms, is expected after an incubation period of approximately 12 to 20 months. However, subtle alterations may already occur during the preceding preclinical phase. These include behavioral changes such as apathy, social withdrawal, or compulsive patterns, as well as early physical warning signs including mild locomotor impairment, loss of condition, and increased sensitivity. The objective of this project is to investigate the preclinical phase of atypical BSE in experimentally infected cows and to identify subtle deviations in behavior and species-specific locomotion prior to the onset of overt clinical signs. Particular emphasis is placed on integrating animal welfare indicators into the analysis, including activity levels, social interactions, spatial use, posture, and movement quality. The study aims to detect quantifiable behavioral and movement parameters that may serve both as digital biomarkers of emerging neurological dysfunction and as objective indicators of animal welfare status. To this end, a computer-assisted monitoring framework based on state-of-the-art computer vision methods is being developed. The central goal is to establish and validate a robust, data-driven model for automated longitudinal anomaly detection, enabling the identification of progressive deviations from individual and group-specific baseline patterns under practical housing conditions. The cows were housed in an experimental barn similar to a conventional dairy cubicle system, without a milking unit. Continuous recording was achieved using four synchronized cameras installed at the barn corners. Multi-camera calibration enabled 3D reconstruction of relevant body points for quantitative analysis of gait, head posture, activity, spatial behavior, and social interactions. YOLO-based convolutional neural networks were trained to detect and track animals and to extract movement-related features. The system allowed reliable individual tracking under practical conditions and generated sufficiently accurate 3D movement data. Initial anomaly detection models identified significant deviations from individual baselines preceding clinically evident neurological symptoms. AI-supported 3D behavioral analysis demonstrates considerable potential for the objective detection of subtle preclinical changes in atypical BSE. Continuously collected movement, behavioral, and welfare-related parameters may serve as digital biomarkers for early neurological dysfunction while simultaneously providing an objective framework for continuous animal welfare assessment. Further research is required to validate model specificity and sensitivity and to distinguish disease-specific effects from age-, developmental-, or environment-related influences. This approach integrates experimental prion research with AI-supported behavioral analytics and offers novel perspectives not only for the automated early detection of neurological diseases in livestock but also for data-driven, continuous animal welfare monitoring under practical farming conditions.

Sniffing the sustainable dairy future: experiences establishing methane emissions monitoring in Swedish dairy herds

I. Ohlsson[1], I. Clegg[2], E. Lövbom[2], E. Rius-Vilarrasa[3], P. Ask-Gullstrand[3], S. Nyman[3], A. Medved[3], B. Gustafsson[3], L. Bark[3], M. Bjerring[4], T. Villumsen[5], T. Klingström[1]

[1] Swedish University of Agricultural Sciences, Animal Biosciences, Box 7023, 750 07 Uppsala, Sweden, [2] Swedish University of Agricultural Sciences, IT, Box 7079, 750 07 Uppsala, Sweden, [3] Växa Sverige, Box 288, 75105 Uppsala, Sweden, [4] Aarhus University, ANIVET Data Group, Blichers Allé 20, 8830 Tjele, Denmark, [5] Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus, Denmark

Issues with mitigation of methane from ruminants are ongoing worldwide. Since 2025 a Nordic Methane index based on Danish data is available in the Nordic Cattle genetic evaluation. While feed additives have a transitive effect and may cause digestive issues for some cows, breeding for an optimized balance of health, milk yield and methane production can produce effects that are permanent and sustainable. During 2025, the Swedish University of Agricultural Sciences (SLU) collaborated with Växa and Aarhus University (AU) within the Global Methane Genetics initiative to install gas sniffers (Guardian NG, Edinburg sensors) on five Swedish dairy farms attached to the SLU cattle data infrastructure Gigacow. This represents the first effort to establish large-scale dairy methane emissions monitoring in Sweden with the purpose of defining breeding values for methane production, with a focus on the local Swedish red and white dairy breed. Integrating the UK-made instrumentation and Danish data collection pipeline with two Swedish cattle databases and five active commercial dairy farms presented a variety of technical and organizational challenges. Here we present our strategies and experiences, and implications for further expansion of methane monitoring as well as international sharing of data. There are a small number of brands of automated milking systems (AMS) in use in Swedish dairy herds, but a greater variety of floorplans in dairy barns. This creates challenges in positioning gas sniffer units and connecting them to their corresponding AMS, power supply and wireless internet. In some cases, ad hoc modifications were necessary to fix sniffers atop AMS units. Sniffers manufactured for the Danish market also had to be modified in the field to add Swedish standard power plugs. The sniffer units were configured to transmit daily batches of output to SLU Gigacow, which was expanded to integrate gas data into the existing SQL database. Several issues with robot, sniffer and farm identities had to be accounted for when constructing the gas data import functionality. An application programming interface was developed along with an online dashboard (available at https://gigacow.slu.se/ – cancel the login prompt to access public data) to provide summary statistics and enable remote monitoring of sniffer function. Work is ongoing to combine cow identities recorded by AMS with the continuous gas measurements from the attached sniffer unit, using a pipeline developed at AU. The lessons learned from installing sniffers at a single pilot farm in south-central Sweden accelerated the installation procedure at a subsequent four farms around the southern half of the country. The remote monitoring system developed by SLU will allow a small team of technicians at Växa to maintain sniffers as needed and relocate them to new farms. Thus Swedish researchers and animal breeders can make a case for regular methane monitoring at dairy farms, define methane efficiency phenotypes in local and international breeds, and improve the sustainability of future dairy herds.

Combining population and quantitative genetics to improve genomic prediction

E. Tourrette[1,2], G. Hélène[1], B. Servin[1]
[1] GenPhySE, Université de Toulouse, INRAE, ENVT, 31326 Castanet-Tolosan, France, [2] Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350 Jouy-en-Josas, France

In breeding populations, the temporal dynamics of a causal allele for a selected trait results from a complex interplay between its effect on the trait, its frequency, the effects and frequency of other causal alleles and the evolutionary constraints affecting individuals (selection, drift, pedigree structure). These parameters will, in turn, also affect the estimation of marker effects and breeding values. However, they are typically not fully accounted for in genomic prediction (GP) models. In this work, we propose to improve genomic prediction models by incorporating additional information on the selection coefficients of the markers, estimated using a method from population genomics. This method, called selnetime (Uhl, Bunel et al. 2025), uses the temporal dynamics of the allele frequency trajectories through generations of selection to estimate a selection coefficient measuring the relative fitness of individuals carrying a particular allele. In a breeding population, we expect the favorable alleles for the trait to increase in frequency over time and therefore have positive selection coefficients. We developed a new statistical approach to re-estimate marker effects from modeling their joint distribution with their selection coefficient, using a meta-analysis method (mash, Urbut et al. 2019). We evaluated the performance of this new approach on simulations of a diverging selection experiment inspired by a real dataset. The selected trait is controlled by both a QTL and a polygenic effect. Additional neutral markers are also simulated, to evaluate the effect of selection on allele frequency dynamics solely due to the pedigree structure resulting from selection across generations. We show that state-of-the art statistical methods for GWAS/GP lead to non-null correlation between quantitative and adaptive effects, not only for the QTL but also for the neutral markers. This latter correlation results from population structure and leads to an overestimation of the estimated breeding values. Re-estimating the quantitative effects with our new approach removes most of the correlation for the neutral markers while preserving good performance at estimating true QTL effects. Overall, our proposed model improves genomic prediction by inducing an additional shrinkage on non-causal variants while preserving true QTL effects. We will discuss the implication of our results for managing breeding populations, in particular its relevance for the classically observed erosion of GEBVs or for cross-population genomic prediction.

Breeding Perspectives on Red and White Dual-Purpose Cattle: Results from a Multinational Survey

M. Albers[1], F. Schmidt[1], Y. Huppertz[2], N. Gengler[3], D. Hinrichs[4], G. Thaller[1], N. Krattenmacher[1]
[1] Kiel University, Institute of Animal Breeding and Husbandry, Olshausenstraße 40, 24098 Kiel, Germany, [2] Elevéo asbl, Rue de la Clef 41, 4650 Herve, Belgium, [3] University of Liège, Gembloux Agro-Bio Tech, TERRA Teaching and Research Center, Passage des Déportés 2, 5030 Gembloux, Belgium, [4] University of Kassel, Faculty of Organic Agriculture, Section of Animal Breeding, Nordbahnhofstraße 1a, 37213 Witzenhausen, Germany

Many local cattle breeds are endangered and some under the thread of extinction. The strong focus on milk production has led to a shift away from local dual-purpose breeds towards highly specialised dairy breeds. However, there are important arguments for the preservation of these local breeds such as maintaining genetic diversity and the adaptability in the face of changing environmental conditions. Red and White Dual-Purpose cattle (RWDP) was formerly spread across the Northwestern part of Germany (GER) but declined strongly in this region. At now, the largest RWDP population in GER is registered in Schleswig-Holstein (SH). Due to the relatively small population size, cooperation with closely related breeds is necessary to establish a reasonable reference population for genomic selection to be competitive. Due to their close relationship Rouge Pie de l´Est from Belgium (BEL) and Pie Rouge de l´Oesling from Luxembourg (LUX) were used in this study (hereinafter collectively referred to as RWDP). Little is known about population differences as well as the breeding perspectives for these three breeds. A multinational survey covering farm and sociodemographic characteristics, herd size and structure, management and breeding aspects and future opportunities was conducted among breeders in GER, BEL and LUX. The questionnaire was accessible from March to May 2024 and reopened for BEL and LUX from October 2025 to February 2026 as no initial responses were received. Overall, 28 (GER), 6 (BEL) and 1 (LUX) questionnaires were answered. In total, the participants kept 1,724 (GER), 290 (BEL) and 60 (LUX) RWDP cows. In GER, 82.5% of the answers came from SH, while in BEL all responses originated from the province of Liége. The proportion of GER farms keeping only purebred RWDP cattle was rather low (22.2%) compared to BEL (100%). In GER, the additional breed in mixed herds was mostly Holstein Friesian. The average herd size was 95 (range: 20-215) in GER, including on average 64 RWDP cows (range: 1-200), 73 (range: 60-110) in BEL and 63 in LUX, including 60 RWDP cows. The RWDP average milk yield is 7,000 kg (range: 5,000-8,000 kg) for GER, 6,083 kg (range: 5,000-7,000 kg) for BEL and 6,184 kg for LUX. Breeding progress (GER) and inbreeding (BEL) were identified as the main future challenges. GER and LUX breeders prefer to maintain type, whereas most BEL breeders aim for a stronger dairy type. Improvement of udder traits was the main priority in GER, while BEL and LUX focused more on output traits such as milk volume, milk components and meat production. Across regions, breeders agreed on the need for a sufficient number of elite sires. Current selection of dams emphasises milk yield and longevity (GER and BEL) and dual-purpose character (LUX). Most breeders would prefer genomic breeding values for selection decisions. Despite the current trend some aspects raise hope for RWDP in the near future. Most breeders are planning to maintain herd sizes and envisage a slight increase in RWDP proportion within herds. Additionally, 79.7% already have a potential farm successor, particularly among farmers aged >55 years. However, the strong confinement to specific regions within country poses a significant long-term risk.

Impact of relationship matrices on inbreeding control in pig populations under optimum contribution selection

K. Kelles[1,2], N. Leite[3], M. Van Son[1,3], Y. Wientjes[4], E. Hanenberg[3], E. Grindflek[1,3], P. Berg[2], T. Meuwissen[2]
[1] Norsvin, Storhamargata, 2317 Hamar, Norway, [2] Norwegian University of Life Sciences (NMBU), Oluf Thesens vei 6, 1433 Ås, Norway, [3] Topigs Norsvin, Meerendonkweg 25, 5216 s-Hertogenbosch, Netherlands, [4] Wageningen University & Research, Animal Breeding and Genomics, P.O. box 338, 6700 Wageningen, Netherlands

Maintaining genetic diversity is a major challenge in animal breeding programs. Optimum Contribution Selection (OCS) is among the most established strategies for balancing genetic gain with the preservation of genetic diversity by limiting the buildup of inbreeding across generations. However, the effectiveness of OCS depends directly on how relationships among selection candidates are defined. In general, the methods to construct the relationship matrix can be classified into 3 approaches: (i) IBD-based methods estimate the probability that alleles are identical due to common ancestry, (ii) Drift-based methods quantify deviations in allele frequency from a base population due to genetic drift, and (iii) Homozygosity-based (HOM) methods estimate genome-wide homozygosity. The choice of relationship matrix determines how the different inbreeding approaches (IBD, Drift, or Homozygosity) will be constrained. Theoretically, FDRIFT and FHOM estimated at neutral loci should be equal when there is no selection. Deviations between these estimates can indicate the impact of selection on genetic diversity, providing insight into whether breeding strategies effectively maintain genetic variation over time. The aim of this study is to evaluate the performance of different relationship matrices in OCS by comparing their effects on genetic gain and inbreeding. The modular breeding program simulator (MoBPS) will be employed to simulate breeding populations. Genomic selection will be based on breeding values estimated using a genomic relationship matrix (G), while six alternative relationship matrices will be used exclusively within the OCS framework to manage genetic diversity. The simulated population will reflect a pig breeding population, including a nucleus population of approximately 120 animals per generation, simulated over 10 discrete generations under genomic selection with OCS to control inbreeding. The genome will be distributed across 18 chromosomes. A total of 5,000 SNP loci will be sampled as marker loci for genomic prediction, 1,000 as additive QTL with allelic effects sampled from a normal distribution, and 1,000 as neutral loci to assess allele-frequency changes and loss of heterozygosity. Six matrices will be used for OCS, namely 2 IBD-based matrices (pedigree relationship matrix (A), and genomic relationship matrix based on linkage analysis (GLA)), 2 drift-based matrices (genomic relationship matrices (G) based on VanRaden methods 1 and 2), and 2 homozygosity-based matrices (runs of homozygosity matrix (GROH), and G matrix with allele frequencies fixed to 0.5 (G0.5)). Obtained genetic progress and inbreeding rates will be investigated using both drift-based and homozygosity-based approaches at neutral loci. The results of this study are expected to identify the most suitable relationship matrix for OCS and to provide practical recommendations for pig breeding programs to sustain genetic progress while controlling inbreeding rate, thereby ensuring the long-term sustainability of genetic improvement.

Performance of optimal contribution selection depends on the accuracy of selection candidates

J. R. Thomasen[1,2], H. M. Nielsen[2], M. Kargo[1,2], S. Tenhunen[3], H. Liu[2]
[1] VikingGenetics, Ebeltoftvej 16, 8960 Randers SØ, Denmark, [2] Aarhus University, Center for Quantitative Genetics & Genomics, C. F. Møllers Alle 3, 8000 Aarhus C, Denmark, [3] University of Helsinki, Department of Agricultural Sciences, Latokartanonkaari, 700790 Helsinki, Finland

Optimum-contribution selection (OCS) balances genetic gain and inbreeding, but its performance depends on the accuracy of genomic evaluations for selection candidates. We quantified how accuracy changes the gain-inbreeding frontier under OCS in a simulated dairy breeding program with an open breeding nucleus. The breeding goal included milk production (h^2 = 0.3) and a functional trait (h^2 = 0.04) with a negative genetic correlation (rg =-0.30). The traits were weighted equally in the breeding goal (~83 per additive genetic standard deviation). A base population of unrelated animals was simulated and assigned to age classes 1-5 years for females and 1-6 years for males. The nucleus consisted of 10,000 lactating cows and approximately 4,500 replacement heifers across 100 herds. Each year 500 one year old males and 2,000 one year old females were genotyped based on parental average of genomic estimated breeding values (GEBV). Bull calves produced via MOET were given priority for selection. Active sires for mating were selected using OCS from the 500 genotyped males. The number of selected sires was determined by the OCS algorithm. Among the genotyped females, 100 with the highest GEBV were chosen as MOET donors, each mated to two sires to produce a total of ten offspring. To vary evaluation accuracy while keeping genetic parameters, population structure, and the breeding scheme fixed, we used a pseudo-genomic evaluation: candidates' GEBV were constructed as noisy predictors of true breeding values (TBV) so that cor(GEBV, TBV) equaled 0.99 (High), 0.70 (Medium), or 0.50 (Low), rather than being obtained from an explicit SNP-based prediction model. The breeding schemes were simulated for 15 years. OCS maximized with g_T C+λ 1/2 c□ Ac with λ {0,-1,-3,-5,-10,-25,-50,-70,-85,-100,-1000}. Outcomes were summarized across replicates and years as 1) annual genetic gain (ΔG), estimated as the slope from a linear regression of TBV on year and 2) the rate of inbreeding (ΔF), estimated from the slope s of the linear regression of ln(1–F) on generation ($\Delta F=1-e_s$). Results showed that the shape of the frontier varies across accuracies. The marginal increase in ΔG by increasing λ from -1000 to -50, were 12.7; 8.3; 6.8 for High, Medium and Low. For penalties lower than -50, increase in ΔG was low. Overall, ΔF varied from 0.14% and up to 0.71% for High, 0.14% to 1.00% for Medium and from 0.16% up to 1.20% for Low per generation across all penalty levels, demonstrating that the maximum achievable ΔF along the frontier decreases substantially with higher accuracy. The preliminary results indicate that the performance of OCS is improved remarkably with higher selection accuracy of selection candidates. In practical breeding schemes, where selection candidates vary in evaluation accuracy across cohorts, further investigation is needed.

Surveying and evaluating UK farm animal genetic diversity estimates

C. M. Rochus[1], C. F. Price[2], I. Pocrnić[1]
[1] Roslin Institute, University of Edinburgh, Easter Bush Campus, EH25 9RG Midlothian, United Kingdom, [2] Rare Breeds Survival Trust, Stoneleigh Park, CV8 2LG Kenilworth, United Kingdom

Local and rare livestock breeds are highly adapted to niche environments and contribute more than expected to overall species diversity. These breeds are reservoirs for the genetic variation needed to face future challenges. Monitoring the genetic diversity found in these populations is key for prioritising resources for conservation purposes. In the UK, there are three sources of information for monitoring: annual diversity estimates published by the Department for Environment, Food and Rural Affairs (DEFRA); an annual watchlist published by the Rare Breeds Survival Trust (RBST), a charity that conserves and promotes native UK livestock and equine breeds; and diversity estimates published in peer-reviewed scientific literature. Our aims were to: (1) summarise genetic characterisation (effective population size (Ne) and inbreeding) of domestic populations in the UK and Ireland; (2) identify populations on the RBST watch list that have genetic diversity estimates in peer-reviewed literature; and (3) compare DEFRA's annually reported (census-based) estimates of Ne with (inbreeding- and DNA-based) estimates from peer-reviewed literature. We identified a total of 37 studies published from 1975 to 2024 with genetic diversity estimates. While 42% of the breeds on the RBST watchlist have been included in peer-reviewed publications with genetic diversity estimates at least once, there were still many breeds, and even a few species (goat, turkey, duck and geese) with no available pedigree- or DNA-based genetic diversity measures. In contrast, 79% of breeds have at least one census-based Ne estimate published by DEFRA. We found census-based Ne estimates were, on average, higher than DNA-based estimates, likely due to violated assumptions in the census-based methodology, because of the structure of livestock mating systems. While breeds identified by the RBST as the highest priority for conservation had similar Ne census-based and DNA-based estimates (average difference 7), the difference increased as the priority level of the population decreased, with the census-based estimates eight times higher than the DNA-based estimates for the lowest priority level (average difference 1468). We recommend that, where possible, DEFRA switch to F-based estimates, and eventually to DNA-based estimates as resources become available. Most of the peer-reviewed publications estimated genetic diversity measures using pedigree, microsatellite markers, or SNPs. However, to identify breed-unique variants responsible for adaptive traits in rare breeds, more studies using whole-genome sequencing will be needed. Having genetic diversity estimates are an important step to identifying breeds at risk, however, future resources should also be directed toward implementing breeding programmes with the aim to conserve genetic variation and unique traits, and improve functional traits. This will require not only pedigree information (and genomic information if possible), but phenotypic records as well.

A genomic survey of the Romagnola beef cattle breed

D. Colombi[1], F. Sbarra[1], F. Perini[2], A. Quaglia[1], E. Lasagna[3]
[1] National Association of Italian Beef-Cattle Breeders (ANABIC), Strada del Vio Viscioloso, 21, 06132 Perugia, Italy, [2] University of Perugia, Department of Chemistry, Biology, and Biotechnologies, Via dell' Elce di Sotto, 8, 06123 Perugia, Italy, [3] University of Perugia, Department of Agricultural, Food and Environmental Sciences, Borgo XX Giugno, 74, 06121 Perugia, Italy

Romagnola is an indigenous Italian beef cattle breed, reared in the Emilia-Romagna region. Although it was considered one of the most promising European beef breeds between 19th and 20th century, it progressively faced a reduction in its use and population. As of 2024, only 8,691 animals are registered in the herdbook. Due to the reduced population size, the risk of genetic erosion is considerable. This work aimed to explore the genomic conservation status of Romagnola breed; to this end, the complete set of genotyped Romagnola animals, consisting of 2,644 animals, and a common panel of 25,445 SNPs was used. The genetically close Marchigiana and Chianina breeds were used for comparison in population structure (i.e., PCA, linkage disequilibrium decay, pairwise FST values, admixture, computed via PLINK v1.9 and ADMIXTURE software); observed and expected heterozygosity, alongside fixation indexes FIS were also obtained via PLINK software, detectRUNS R package was used to detect runs of homozygosity, while SNeP1.11 software was used to estimate the effective population size. Results indicated, beside an evident genetic similarity with the other two breeds, a strong genetic identity for Romagnola, being the first to be differentiated by ADMIXTURE, and no faster linkage disequilibrium decay compared to the Chianina breed, which has not undergone genetic bottlenecks as Romagnola. FIS values resulted in an average of -0.005, confirming the lack of inbreeding and no relevant deviation from Hardy-Weinberg equilibrium. Nonetheless, the trend for such value across the years shows a progressive increase, although FIS is still close to 0, reaching 0.009 in 2024. Regarding the runs of homozygosity, on average each animal showed 27 regions under selection, with an average of 8.3 Mb of length, with the higher percentage of longer runs indicating more recent selection and inbreeding. Finally, the effective population size was 156 as of 13 generation ago, and a constant and linear decrease in the past 50 generations can be noticed. The analysis of genetic and genomic diversity in Romagnola breed did not evidence severe inbreeding conditions, but its increasing trend suggests progressive genetic erosion. Moreover, since its reduced population, and the constant and progressive decrease in census, the continuous monitoring is fundamental to support the efforts to preserve and valorize this breed. Funding: Regione Emilia-Romagna. Deliberazione della Giunta regionale n. 553/2025. Programma Operativo Regionale Triennale. Determinazione n° 23607 del 28 novembre. CUP E98H25001250009.

Seven decades in liquid nitrogen: Viability and fertility of historic bovine semen

R. Herbicht[1], K. Jilek[1], C. Klein[1], H. Henning[1]
[1] Friedrich-Loeffler-Institut, Institute of Farm Animal Genetics, Höltystraße 10, 31535 Neustadt, Germany

Gene banking of farm animal gametes serves as a critical safeguard for biodiversity, providing a biological insurance policy against diseases, climate change, and the loss of heritage lineages. While cryopreservation of semen is an established, routine procedure for long-term storage of male genetics, the theoretical time limits of storage are rarely tested over spans exceeding several decades. Validating the viability of long-term stored gamete samples is essential for confirming the efficacy of gene banks. This report details the functional analysis of semen samples of three German Black Pied cattle (DSN) bulls born in 1952, 1953, and 1966. These samples remained in cryostorage for 60 to 70 years. To evaluate the impact of ultra-long-term storage, the historic samples were compared against a control bull whose semen was cryopreserved in 2011 under modern EU standards. For each sample, semen quality parameters were assessed post-thaw. Kinetic data were collected via computer-assisted sperm analysis (CASA). Structural integrity was evaluated through flow cytometry, simultaneously assessing viability and acrosome integrity. To investigate potential cumulative genetic decay, DNA fragmentation was quantified using the sperm chromatin structure assay (SCSA). Furthermore, the functional competence of the historic germplasm was tested through in vitro embryo production (IVP) using oocytes retrieved from slaughterhouse ovaries. Post-thaw analysis revealed that while kinetic parameters presented a chronological decline, structural and genetic integrity remained remarkably high after ultra-long-term storage. Total motility for the bulls born in 1952 and 1953 was 17.1% and 14.0%, respectively, compared to 46.9% for the 1966 bull and 56.5% for the control bull. Flow cytometry confirmed that 16.5% (1952), 7.1% (1953), and 22.9% (1966) of the sperm populations maintained intact plasma and acrosome membranes. Most notably, the DNA fragmentation index (DFI) remained exceptionally low across all historical samples, comparable to the control sperm (0.5-1.0% vs. 0.1%). Morphologically normal spermatozoa were present at rates of 65.0% to 76.5% in the historical samples. Functional competence was confirmed through IVP, where the historic samples successfully achieved fertilization and progression to the blastocyst stage. The 1952 and 1953 samples each produced 10 blastocysts, while the 1966 sample produced 9 blastocysts. All embryos reached the blastocyst stage by day 7/8 and were classified as quality 1 or 2, suitable for cryopreservation. These findings validate the long-term efficacy of gene banking and confirm that germplasm from the pioneering era of cryopreservation remains a high-quality, biologically viable resource for modern biodiversity restoration and the genetic conservation of heritage breeds such as the German Black Pied cattle.

Genomic diversity and population structure in Nordic Red Dairy Cattle populations

S. Tenhunen[1], L. P. Sørensen[3], A. Gjuvsland[4], J. R. Thomasen[2,3], M. Kargo[2,3], P. Uimari[1]
[1] University of Helsinki, Agricultural Sciences, Koetilantie 5, 00014 Helsinki, Finland, [2] Aarhus University, Quantitative Genetics and Genomics, C. F. Møllers Allé 3, 8000 Aarhus, Denmark, [3] VikingGenetics, Ebeltoftvej 16, 8960 Randers SØ, Denmark, [4] Geno SA, Geno SA Storhamargata 44, 2317 Hamar, Norway

The Nordic Red Dairy Cattle comprises two main populations: the Red Dairy Cattle (RDC) and Norwegian Red (NR). The RDC breeding program, coordinated by VikingGenetics, unites Danish Red (DNK), Finnish Ayrshire (FIN), and Swedish Red (SWE) cattle within a joint genomic selection program. The NR breed (NOR), managed by Geno SA in Norway, has been developed independently under similar breeding objectives and with comparable selection intensity. Both breeding programs are supported by long-standing national recording and evaluation systems, which have enabled early adoption of genomic selection and a shared emphasis on production efficiency, health, and functional traits. Intensive selection within relatively small breeding populations, together with historical gene flow between the RDC and NR populations, has likely influenced patterns of genetic diversity and relationships among individuals, yet the extent and nature of these changes have not been comprehensively assessed. This study investigates the population structure and genomic diversity of RDC and NR AI bulls using medium-density SNP genotype data. The bulls were categorized into three groups: Group 1 represents animals born before the combined Nordic breeding program for RDC (prior 2009); Group 2 includes bulls from the era of the joint RDC program but before the implementation of genomic selection; and Group 3 consists of bulls after the full-scale adoption of genomic selection from 2015 onwards until the end of 2025. Population structure was characterized using Principal Component Analysis (PCA) and ADMIXTURE, while genetic differentiation was quantified using Fixation Index (FST). The PCA results revealed a clear trend of population unification within the RDC over time. Group 1 showed distinct clusters for DNK, FIN, and NOR bulls, with SWE bulls positioned between the FIN and NOR. In Group 2, the DNK and FIN bulls began to cluster more closely with the SWE bulls. By Group 3, the RDC bulls displayed substantial genomic convergence, reflecting the long-term impact of coordinated selection within the unified Nordic program. The NOR bulls consistently formed a distinct clade, maintaining genetic separation from the RDC across all three eras. ADMIXTURE analysis, conducted up to K=14, showed no clear plateau in cross-validation error, indicating a complex, highly admixed history of these populations. Despite this, clear group-specific trends were evident: Group 1 bulls displayed distinct country-specific admixture profiles, while in Group 3, the RDC bulls exhibited highly similar genomic compositions across countries. Throughout these eras, the NOR maintained a distinct admixture profile. These structural shifts were corroborated by FST analysis, which identified FIN and SWE populations as the most closely related. The highest historical differentiation was observed between DNK and FIN bulls in Group 1 (FST = 0.062), showing the genetic distance before integration. Furthermore, significant genetic drift within countries was evident over time, as seen in the FST distance of 0.034 between DNK bulls in Group 1 and Group 3. These findings show that past and ongoing breeding strategies have driven increased genomic similarity within the RDC population, while the NR population has maintained its distinct genetic profile. Together, the results reflect the long-term effects of selection within each breeding program and highlight the importance of continued monitoring of genetic diversity in both populations.

Global Variability of the Chicken D-Gene Region

J. Geibel[1], M. Brunner[2], A. Weigend[1], C. Reimer[1], T. V. L. Berghof[2], S. Weigend[1], B. Schusser[2,3]
[1] Friedrich-Loeffler-Institut, Institute of Farm Animal Genetics, Höltystraße 10, 31535 Neustadt, Germany, [2] Technical University of Munich, Reproductive Biotechnology, Liesel-Beckmann-Str. 1, 85354 Freising, Germany, [3] Technical University of Munich, Center for Infection Prevention (ZIP), Liesel-Beckmann-Str. 1, 85354 Freising, Germany

New emerging diseases and the increasing societal demand to keep chickens in less protected environments fosters the need for chickens with an immune system that allows reaction to those challenging environmental impacts. One critical component for an adaptive immune system is a variable repertoire of naive B-cells, which allows the generation of a broad spectrum of antibodies. Thereby, the antibodies consist of a heavy and a light chain. The light chain is encoded in the genome by a VL and a JL segment, while the heavy chain consists of a VH, DH and a JH segment. In vertebrates, immunoglobulin (Ig) diversity originates from the somatic recombination of the V- D- and J-gene segments in the Ig heavy chain locus, and V- and J-gene segments in the light chain locus with antibody diversity, in mammals further expanded by gene conversion. In contrast to mammals, chicken possess only one functional VH gene, followed by a cluster of DH segments and a single functional JH segment, limiting the combinatorial potential of V(D)J recombination. To date, the only published study on the native reservoir of chicken D-genes by Reynaud and Weill (1991) describes 16 distinct D-genes (very homologous D1-D15 and the slightly more different Dx) identified through Sanger Sequencing of chicken B-cells. However, only nine copies of D-genes are resolved in the current chicken reference genome GRCg7b with other published reference genomes varying between 3-19 D-gene copies. Further, studies in other vertebrates also describe the D-gene region as copy-number variable, suggesting a potential association between the number of germline D-genes and the adaptability of the immune system. The present study therefore aims to investigate the global variability of the chicken D-gene region, with the long-term goal of identifying potential global variation that could be valuable for current breeding programs. To explore the genetic diversity of the D-gene region in a broad set of breeds, we amplified the ~10-25kbp long D-gene region in 124 samples of 79 chicken breeds or lines (economically relevant breeds as well as German fancy and local breeds). The amplicons were sequenced using Nanopore sequencing and a custom pipeline was developed to phase and polish the D-gene haplotypes. D-gene sequences were identified by similarity matching to the 16 known sequences. Additionally, for a subset of the samples also the recombined region of the heavy chain was amplified from B-cells and Illumina Sequencing was used to analyze the usage of the germline encoded D-genes. A clustering of the newly identified D-gene sequences identified distinct clusters of D-genes being closely related to Dx, D1 and D2 respectively, while the other genes formed a relatively undifferentiated large cluster. This structure was also seen in the germline arrangement of the genes, with each haplotype starting with a D1, followed by a Dx and a D2 gene. This conserved region was followed by a variable number of genes from the large gene cluster. Overall, the different haplotypes consisted of 4 to 29 D-gene copies with a mode of nine D-gene copies, uncovering a broad global variation. This exemplarily highlights that chicken genetic resources offer a broad reservoir of unique diversity, which is potentially relevant for an adaptable immune system. Nevertheless, the direct link between the diversity of the D-gene region and the adaptability of the chicken immune system needs to be investigated by further research.

Genomic consequences of a historical bottleneck after demographic recovery in the Old Norse sheep

C. Brekke[1], P. Berg[1]
[1] NMBU, Institute of Animal and Aquacultural sciences, Arboretveien 6, 1433 Ås, Norway

Population bottlenecks can have long-lasting consequences for genomic diversity, patterns of inbreeding and the distribution of deleterious mutations, even in populations that later recover numerically. The Norwegian Old Norse sheep is one of the oldest sheep breeds in Scandinavia and belongs to the group of North European short-tailed sheep including Icelandic, Faroese and Soay sheep. The present population of old Norse sheep is considered a direct descendant of the ancestral sheep type present in Norway prior to the introduction of modern breed classifications and unlike many modern breeds, the breed has not been subject to intensive selection for production traits, but rather for individuals capable of thriving outside under extensive grazing systems throughout the year. This has resulted in a hardy sheep adapted to rough grazing environments, characterized by efficient resource use, easy lambings and a double-coated fleece with natural wool shedding. During the mid-twentieth century the population experienced a severe demographic bottleneck, followed by substantial numerical recovery in recent decades. Today the breed is no longer considered threatened based on census size. In this study we investigate the genomic consequences of the demographic history by analysing whole-genome resequencing data from 16 Old Norse sheep AI rams sequenced at >15X coverage. We identify runs of homozygosity (ROH) and partition them by length to distinguish signals of recent inbreeding from historic inbreeding. Most individuals showed low levels of recent inbreeding (FROH ≈ 0.01–0.04 for ROH >8 Mb), although a small number of individuals display elevated levels consistent with recent inbreeding events. Shorter ROHs occur at a relatively higher and similar levels across individuals, reflecting shared historical autozygosity likely associated with the known population bottleneck. Using genome-wide variant annotation, we further investigate whether the demographic history of this population shows genomic evidence of purging of highly deleterious mutations or accumulation of mildly deleterious mutations. Together, these analyses provide insight into how bottlenecks followed by demographic recovery shape genomic diversity and mutation load in managed animal populations and highlight the importance of genomic characterization for the conservation and sustainable use of livestock genetic resources.

Native African cattle as important genetic resource for environmental adaptation

J. Friedrich[1], S. Kambal[2,3], N. A. Adossa[3], A. M. Ahbara[4], M. T. Makumbe[5], O. Matika[1], J. M. Mwacharo[6], K. Bougiouri[7], F. Racimo[7], O. Hanotte[3,8], P. Wiener[1]

Native African cattle represent a fascinating genetic mosaic of Bos taurus x Bos indicus, shaped by a complex demographic history and natural selection for adaptation to a vast range of environments. At the core of sustainable agriculture in developing countries is the promotion of locally adapted populations. It is essential to capture the genetic diversity and gain insights into the genetic background that allows native populations to thrive under specific circumstances. Multiple studies have focused on finding selection signatures within and between native African cattle breeds. However, many adaptation traits are associated with the genetic composition rather than breeds per se, i.e. the proportion of indicine and taurine backgrounds, where breeds with a higher taurine proportion have been described as more trypanotolerant while indicine animals are better adapted to drought and heat stress. In this study, we employed different methods to detect selection on ancestral backgrounds (i.e., high taurine or indicine proportions and hybrids), based on whole-genome short -reads sequence data from over 40 breeds from West, Central, East, and Southern Africa. We identified various signals of ancient selection with the respective methods. Results from this study may inform breeding for genetic backgrounds with relevant adaptation mechanisms.

Comparison of genomic vs pedigree-based inbreeding in the Italian Simmental cattle breed

N. Macciotta[1], L. Degano[2], D. Vicario[2], C. Dimauro[1], A. Cesarani[1]
[1] University of Sassari, AGRARIA, Viale Italia 39, 07100 Sassari, Italy, [2] ANAPRI, Via Ippolito Nievo 19, 33100 Udine, Italy

Inbreeding is a relevant element of the genetic structure of a livestock population, that has to be considered for its genetic improvement and management of genetic diversity. Inbreeding calculation has been traditionally based on the pedigree (INB_PED). The outbreak of genomics has made available tools for calculating the genomic inbreeding (INB_GEN) based on metrics derived from molecular markers. In this work, the pedigree-based and different measures of genomic inbreeding are compared in Italian Simmental breed cattle. A data set of 5,817 primiparous cattle genotyped with the illumina 50K beadchip were analyzed. After edits, 42,100 SNP were retained for further analysis. The following metrics of inbreeding were calculated: the pedigree based (FPED) calculated with a recursive method; genomic relationship matrix based inbreeding coefficient using observed (FGRM) or fixed at 0.5 (FGRM0.5) base allele frequencies; whole genome runs of homozygosity (ROH) based inbreeding coefficient (FROH) calculated with different minimum length classes (2, 4, 8, 16 Mb). Inbreeding depression for milk yield was calculated with a linear model where the EBV was fitted with a random effect of the herd-year combination and the fixed covariable of the inbreeding metrics. The FPED showed a moderate correlation (0.44) with the FGRM0.5 and quite large (>0.55) with ROH-based metrics except FROH16. FGRM0.5 was highly correlated with all FROH measures (>0.75), whereas correlations of FGRM with all other metrics were lower. Principal component analysis (PCA) extracted 4 components able to explain 96% of the original variability. The first (71% variance) was associated mostly with FGRM0.5 and FROH metrics, the second (12%) with FGRM, the third (8%) with FPED, and the fourth (5%) mostly with FGRM0.5 and FROH16, respectively. Factor analysis showed partly similar results. Inbreeding depression estimates were larger for FROH based metrics, with a tendency to increase as the minimum length of ROH included in the inbreeding calculation increased. Pedigree-based and genomic inbreeding show a large degree of concordance and they can be considered together for having a more comprehensive picture of the inbreeding. ROH based metrics allow for estimating separately recent and remote inbreeding.

Detection of homozygosity and heterozygosity rich regions on German Black-Headed Mutton x Kıvırcık (Bandırma) sheep population

S. Koncagül[1], A. Özdemir[2], A. Kasakolu[1,3]
[1] Ankara University, Department of Animal Science, Faculty of Agriculture, 06110 Ankara, Turkey, [2] International Center for Livestock Research and Training, Ministry of Agriculture and Forestry, 06800 Ankara, Turkey, [3] Ankara University, Graduate School of Natural and Applied Sciences, 06110 Ankara, Turkey

Runs of homozygosity and heterozygosity (ROH and ROHet, respectively) are widely considered to reflect selection pressures and population balances in different livestock species. Investigating these regions is important for shedding light on historical selection and balancing events in populations. In the present study, a total of 391 Bandırma sheep were genotyped using the 50K Affymetrix Ovine Array and mapped onto the "Ramb. V3" reference genome. Following the quality control pruning process, a total of 274 unrelated animals with 40,299 variants were used for further investigations. In terms of detection methods, the model-free method was applied using "DetectRUNS" for both homozygous and heterozygous states. Additionally, QTL enrichment analyses were performed using the "GALLO" package and "animalQTLdb" in R, detecting a total of 7,633 and 904 regions for ROH and ROHet states, respectively. Among these regions, ROH islands on chromosomes 2 and 3 of the ovine genome (OAR-2 and OAR-3, respectively) were found to be significantly enriched for production traits regarding body weight (padj < 1.00E-22) and body circumference (padj < 0.05), with a shared frequency of at least 10% in the population. In addition to these regions, islands located in OAR-9, OAR-18 and OAR-20, which represented 10% of the population, were found to be significantly enriched in exterior (padj < 0.05), health (padj < 0.05) and wool (padj < 1.00E-7) traits, respectively. Investigating the ROHet regions, the OAR-2 ROHet region was significantly enriched for body weight (padj < 1.00E-16), which could be considered a balancing region for body weight on OAR-2. Three additional ROHet regions were identified as QTL-enriched regions. These were located on OAR-8, OAR-3 and OAR-6 and were found to be enriched in wool traits (padj < 1.00E-15; padj < 0.01) and health traits (padj < 0.05). In addition to these results, the genomic inbreeding and diversity coefficients were observed to be 0.0740 ± 0.02880 and 0.0018 ± 0.00087, respectively. Thus, this study provides promising insights into the heterozygous and homozygous states of regions in the ovine genome.

Associations between individual-specific genetic correlations and gametic variability

S. Chalhoub[1], P. Croiseau[1], P. Martin[1], D. Boichard[1], B. Cuyabano[1]
[1] Université Paris Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France

Understanding the genetic relationships between traits in dairy cattle systems is critical for the optimal selection of candidates. For example, the genetic antagonism between milk production and conception rate has been widely reported and studied, as such genetic relationships that present a trade-off between traits requires particular attention in breeding programs, to avoid that selection for a trait has a negative effect on the other. This trade-off is quantified by genetic correlations that are negative, and typically estimated as a populational parameter. Such a measure, however, is limited in their ability to comprehend this genetic trade-off at the individual level. While genetic correlations at the populational level have been an effective information to manage trade-offs on a populational context, it ignores the individual's potentially different capacities to manage such joint management of the traits. Recent studies have shown indeed that genetic correlations, including the negative correlation between production and fertility traits in dairy cattle, may differ among the many sires in the selection nucleus. These studies have speculated that such differences in the genetic correlations expressed by different sires may be the partial expression of physiological traits responsible to jointly regulate such traits. Furthermore, aside of potential physiological effects on the expressed genetic correlations between traits, studies on genetic trade-offs between traits usually ignores the recombination of alleles caused by crossovers in the chromosome during meiosis, which will have an effect on the gametic covariances. Thus, two genetically similar sires can pass down different genetic covariability between traits, which can be hard to scale. Our study aimed to associate gametic diversity to the different levels of genetic correlations expressed by ~1500 different sires in a dairy cattle population, for which individual-specific genetic correlations (iSGC) were previously calculated. These sires were genotyped with the Illumina Bovine SNP50 BeadChip (50k SNPs), and for each sire, their phased genotypes were recombined into gametes. Each gamete was created . Finally, the variability of the gametes' variances was compared to the sire's iSGC. This gametic variability was calculated on the whole 50k SNP-genotypes, and on only the SNPs that were targeted as significantly associated with the iSCG obtained between milk yield (MY) and cow conception rate (CR), traits that presented a populational genetic correlation of -0.15. The variability of the gametes specifically on the SNPs that were significantly associated with the iSGC, showed a correlation of 0.1 with the iSGC themselves. This correlation value was approximately twice as large as the one between the gametic variability on the whole genome, suggesting that recombinations at these genomic sites are more relevant, and more strongly associated with observed iSGC differences. Previous studies have already shown that gametic variability depends on heterozygosity at the QTL, and on the linkage disequilibrium between them. Our results indicate that while recombinations explains a part of the differences in iSGC, they still do not explain all their differences, suggesting that other genetic/physiological mechanisms could be responsible for these differences in capacity for trade-off management, which should be studied with further studies, so that the inclusion of these effects can be optimally accounted for in selection and breeding programs, thus allowing better management for genetic trade-off and further sustainable livestock systems.

Analysis of β-casein and β-lactoglobulin variant frequencies in Podolica beef cattle

D. Colombi[1], F. Sbarra[1], F. Perini[2], G. Pedota[3], A. Quaglia[1], E. Lasagna[4]
[1] National Association of Italian Beef-Cattle Breeders (ANABIC), Strada del Vio Viscioloso, 21, 06132 Perugia, Italy, [2] University of Perugia, Department of Chemistry, Biology, and Biotechnologies, Via dell' Elce di Sotto, 8, 06123 Perugia, Italy, [3] Associazione Regionale Allevatori della Basilicata, Via dell'Edilizia, 2d, 85100 Potenza, Italy, [4] University of Perugia, Department of Agricultural, Food and Environmental Sciences, Borgo XX Giugno, 74, 06121 Perugia, Italy

Podolica cattle is an autochthonous Italian beef cattle reared in Southern Italy and valued for its rusticity and adaptability to extensive farming systems. Although exclusively bred and selected for beef purposes, its milk is commonly used to produce the typical Caciocavallo cheese on which studies are being conducted to characterize its chemical and microbiological properties, aimed at applying for Protected Designation of Origin certification. Nonetheless, the relatively small size of the breed, the rusticity of the farming system, and its selection schemes that require most of the produced milk to be used for the calf, make Podolica's genetic characterization of milk proteins still unexplored. Among the proteins related to cheesemaking, β-casein constitutes up to 45% of the total casein count, while β-lactoglobulin is the major whey protein in milk. The aim of this work was to genetically characterize the allelic variants of such proteins in Podolica milk. Variants were characterized by SNP genotyping of 208 Podolica cows via medium density SNP arrays (55 or 100K); population genetic values such as allelic and genotypic frequencies, observed and expected homozygosity, fixation index (FIS), effective allele number (Ne), polymorphic information content (PIC), and eventual deviation from Hardy-Weinberg equilibrium were assessed for both loci. Alleles A1, A2, B, and I were observed for β-casein, with allelic frequencies of 0.37, 0.59, 0.02 and 0.02, respectively. Regarding genotypic frequencies, no BB, nor BI genotypes were observed, the observed homozygosity resulted of 50%, and no deviation from Hardy-Winberg equilibrium was detected. β-lactoglobulin showed a relevant majority toward the B allele, with a frequency of 0.86 compared to the A variant, an observed homozygosity of 78% and no deviation from Hardy-Winberg equilibrium. FIS values were negative and close to 0 for both genes, suggesting genetic equilibrium and absence of population substructure, Ne resulted of 2 for β-casein and 1.3 for β-lactoglobulin, while PIC was moderate for β-casein and lower for β-lactoglobulin. These results suggest the presence of favorable alleles for cheesemaking, however the substantial equilibrium of alleles confirm that milk production is not the main aptitude of the breed. Further studies are needed to investigate allelic variants in other milk proteins, and to understand the possible impact of different genotypes in milk chemical and technological traits.

Genetic diversity and effective population size in the Belgian Landrace pig: insights from SNP genotypes and pedigrees

S. Guan[1], R. Meyermans[1], W. Gorssen[2], K. Hooyberghs[1,3], L. Chapard[4,5], N. Buys[1], S. Janssens[1]
[1] Center for Animal Breeding and Genetics, Department of Biosystems, KU Leuven, Kasteelpark Arenberg 30, 3001 Leuven, Belgium, [2] ETH Zürich, Animal Genomics, Universitätsstrasse 2, 8092 Zürich, Switzerland, [3] Unit of Animal Genomics, GIGA and Faculty of Veterinary Medicine, University of Liège, Avenue de l'Hôpital 11, 4000 Liège, Belgium, [4] Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, [5] IDELE, 149 Rue de Bercy, 75012 Paris, France

Monitoring genetic diversity is essential in small livestock populations, where genetic drift and unbalanced sire use can rapidly increase inbreeding and compromise long-term viability. Belgian Landrace, also called Belgisch Negatief Landras (BN), is a local pig breed in Belgium that currently comprises approximately 70 active breeding sows and has a breeding history strongly shaped by selection for stress resistance. Stress susceptibility is associated with poorer technological meat quality (PSE-related traits) and compromised animal health and welfare. Therefore, interest in breeding stress-negative animals has remained high. Here, we provide a genomic and pedigree-based analysis of diversity and effective population size (Ne) in BN using a cohort genotyped with the Porcine GGP 50K SNP array. The dataset included 184 BN pigs (42 boars, 142 females) sampled across 10 farmers, including one artificial insemination station. After quality control, 34,406 SNPs were retained. Genotype completeness was high and SNP markers were informative (median MAF=0.3025). Population structure analysis via PCA suggested modest stratification. PC1 and PC2 explained approximately 21% of total variance and the PCA plot showed no clear subpopulation clustering. Pairwise genomic relatedness indicated widespread coancestry, with 5,530 pairs in the 0.05–0.125 bin, 2,202 in 0.125–0.25, 660 in 0.25–0.5, and 165 pairs ≥0.5, highlighting practical constraints for avoiding close-kin matings. Mean observed heterozygosity was 0.40 and expected heterozygosity averaged 0.38, indicating that genetic variation persists but is unevenly distributed among individuals. Linkage disequilibrium (LD) decay supported a constrained effective size, with R^2 declining to ≤0.2 at ~350 kb and to ≤0.1 at ~1.65 Mb. LD-based Ne increased with time depth (median Ne ≈21.1 at ~8 generations, 35.7 at ~50, and 59.7 at ~100), indicating a smaller recent Ne relative to deeper history. Pedigree-based Ne declined from 46–47 in 2020–2021 and 45 in 2022 to 33 in 2023, consistent with increased recent coancestry. Our results provide a quantitative update based on broader genomic sampling to support monitoring of the breed. Overall, raised genomic relatedness, extended LD and low recent Ne emphasize the need for conservation oriented management in BN. Priorities include kinship aware mate allocation and balancing genetic contributions of boars and herds, especially in AI semen distribution systems. In addition, Ne and relatedness should be monitored routinely using a pipeline consistent workflow to evaluate management impact over time. Ongoing work will compare BN with other Landrace lines (e.g., French and Dutch) using frequency based (FST, θπ) and haplotype-based scans to identify divergent regions contributing to BN distinctiveness and to inform conservation decisions.

Phenotypic data to assess the resilience potential of Sicilian cattle breeds in the context of climate change

A. Antoci[1], S. Tumino[1,2], M. Carlentini[1], G. Chessari[1], A. Criscione[1], S. Bordonaro[1,2], D. Marletta[1,2]
[1] University of Catania, Di3A, via Santa Sofia, 95123 Catania, Italy, [2] Centro Interuniversitario A.SI.ZO.CA. CLI, via Santa Sofia, 95123 Catania, Italy

Heat stress is a major limiting factor for animal welfare and productivity in livestock systems, especially in Mediterranean areas. Local cattle breeds raised in challenging climates may show different physiological adaptations to high temperatures compared with specialized breeds. Precision livestock farming technologies enable real-time monitoring of physiological and phenotypic parameters, offering new opportunities to study cattle responses to thermal stress. This study assessed the physiological response to different climatic conditions in two native Sicilian breeds, Modicana (MOD) and Cinisara (CIN), reared in extensive systems, in southeastern Sicily integrating IoT sensor data with hematological and hormonal analyses. Wearable IoT sensors integrated into neck collars continuously recorded heart rate (HR), skin temperature (T_skin) and tri-axial acceleration in MOD (n=13) and CIN (n=12) cows. Trials were conducted in the thermoneutral (February) and hot (July) seasons. Each experimental period included 20 days of monitoring, with blood samples collected at the beginning and end for hematological analysis. The Temperature Humidity Index (THI) was calculated from meteorological station data. Animal activity was expressed as an hourly index derived from accelerometer data. Linear mixed models for repeated measures evaluated the effects of breed, season and their interaction, with THI as a covariate. Overall, 13,330 post-QC HR and T_skin records were collected hourly using wearable IoT sensors hourly for 20 days per season. Heart rate showed significant effects of season and breed, with higher values in winter than in summer (72.2 vs 67.4 bpm), and overall higher HR in MOD than in CIN (74.9 vs 64.4 bpm). Skin temperature was significantly higher in summer, with a significant breed × season interaction: MOD showed higher T_skin values than CIN during summer (37.4 vs 32.8 C°). This suggests different heat-dissipation potential between breeds. Complete blood count results showed significant seasonal and breed × season effects on total white blood cell count (WBC), with higher values in summer in both breeds. Neutrophil counts were higher in winter, particularly in CIN. Lymphocyte percentage was higher in CIN, especially in summer, possibly reflecting a stress-coping mechanism. Eosinophils were higher in MOD and in summer, whereas basophils and monocytes did not vary significantly. Absolute counts confirmed these trends, with the highest neutrophil counts in winter and the highest lymphocyte counts in CIN regardless of season. CIN showed higher red blood cell (RBC) and hematocrit (Hct) values than MOD, particularly in winter. Hemoglobin was higher in winter in both breeds, with peak values in CIN. Erythrocyte indices showed breed differences, with higher mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) in MOD, while mean corpuscular volume (MCV) was slightly higher in winter. The endocrine profile was also analyzed. Cortisol showed only breed-related differences, with higher mean values in MOD. Thyroid hormones (T3 and T4) showed a significant breed × season interaction, while insulin did not differ between breeds or seasons. Overall, results indicate seasonal modulation of hematological traits and breed-specific physiological responses to thermal conditions. This study was carried out within the Agritech National Research Center and received funding from the Next-GenerationEU (PIANO NAZIONALE DI RIPRESA E RESILIENZA (PNRR)– MISSIONE 4 COMPONENTE 2 INVESTIMENTO 1.4 – D.D. 1032 17/06/2022 CN00000022).

Challenges for the Conservation of Farm Animal Genetic Resources under Emerging Animal Diseases

E. Sosin[1], A. Chełmińska[1]
[1] National Research Institute of Animal Production, Department of Farm Animal Biodiviersity Conservation and Horse Breeding, Sarego 2, 31-047 Kraków, Poland

Infectious diseases constitute one of the greatest threats to the genetic resources of farm animals, leading to declines in population size, reduced breeding value, and the loss of valuable functional traits. In recent years, animal genetic resources in Poland have been under significant pressure due to the occurrence of infectious diseases. Particularly severe impacts have resulted from outbreaks of African swine fever (ASF) and highly pathogenic avian influenza (HPAI) or bluetongue disease. At the same time, the risk of other major epizootic diseases, such as foot-and-mouth disease, remains present. Outbreaks of highly contagious diseases may result in the mass culling of herds, which significantly reduces the genetic diversity of populations. Diseases and the measures taken to control them also affect the implementation of breeding and conservation programmes. Particularly vulnerable are local and endangered breeds, which are characterised by small population sizes and limited security in gene banks, making the recovery of populations after epidemic losses more difficult. Mainstream breeds are generally characterised by larger population sizes, a wider geographical distribution, and better preservation of biological material in gene banks and artificial insemination centres. However, the occurrence of infectious diseases in large, highly specialised populations may lead to significant production losses and disruptions in food supply chains. An additional risk factor is the concentration of herds in a limited number of breeding centres. For some breeds, the number of herds is small and their location is concentrated in only a few places. In the event of an outbreak of an infectious disease, this may lead to the simultaneous loss of a large part of the population. Moreover, populations included in conservation programmes are often maintained in relatively small herds, which limits their ability to recover quickly after potential losses. Within genetic resources conservation programmes in Poland, 89 breeds, lines or varieties are maintained in 3,335 herds, comprising more than 120,000 females. Among them are, for example, laying hens (13 breeds, 19 herds, 12,563 females), geese (14 breeds, 15 herds, 4,726 females) and ducks (10 breeds, 10 herds, 4,152 females). Gene banks maintain a limited collection of semen, mainly from cattle, and a small collection of embryos from cattle and pigs. Some endangered populations are maintained in public stations; however, the majority remain insufficiently secured. Current regulations ensure that information on herds included in conservation programmes is communicated to veterinary authorities; however, mechanisms for rapid feedback and clearly defined procedures in the event of threats to these populations are lacking. To reduce the risk of losing farm animal genetic resources, systemic measures are needed. These should include the development of early warning and rapid information exchange systems between institutions responsible for genetic resource conservation, breeders and veterinary services, as well as the establishment of clear procedures for responding to epizootic threats and the creation of backup herds for the most endangered populations. It is also essential to strengthen the preservation of biological material in gene banks for both local and key commercial breeds that play an important role in livestock production. Such measures would help safeguard valuable genetic resources while also supporting the stability of livestock production and overall food security.

From concept to measurement: Advancing resilience analysis in small ruminant farming systems

D. Martin-Collado[1], A. Bernués[1], M. Y. R. Couto[1], A. Prat-Banhamou[1]
[1] Agrifood Research and Technology Center of Aragon (CITA), Animal Science, Avda. Montañana 930, 50059 Zaragoza, Spain

Small ruminant farming systems in Europe operate under accelerating and overlapping pressures derived from global change. Market volatility, policy reforms, labour shortages, shifting societal expectations, and climate-related disturbances are reshaping the conditions under which sheep and goat farms remain viable. These farms function as tightly interconnected socioecological systems, where economic performance, land and feed resources, labour organization, and farmer agency co-evolve. Understanding resilience in this context requires going beyond the narrow logic of "can animal and farm performance be further optimized?" to examine how farms, farmers, and farming communities interact and respond to challenges by withstanding shocks (robustness), adjusting practices (adaptability), or reorganizing their systems more fundamentally (transformability). Over the past decade, resilience has become a central concept in farming systems analysis and policy arenas, yet key gaps persist. First, resilience is often addressed conceptually, with limited translation into operational and comparable indicators at the farm level. Second, resilience assessments have traditionally focused on structural attributes and adaptive capacity at the farm level, often overlooking farmers' psychological resources, despite increasing evidence that job discomfort, and life distress are critical bottlenecks for long-term viability. Third, many empirical studies rely on static assessments or on farmers' perceptions, despite resilience capacities being inherently dynamic processes. Finally, analyses conducted at aggregated sectoral scales tend to overlook the contextual specificities of different farms, production orientations and territories. This invited talk synthesizes results from a set of complementary studies developed in recent years on Spanish small ruminant systems (meat sheep, dairy sheep and dairy goat). Together, these studies move from conceptual operationalization to dynamic quantification and explanatory analysis of resilience capacities. They combine longitudinal quantitative data, farm-level structural indicators, econometric and dynamic modelling, participatory approaches, and survey-based assessments of farmer perceptions and psychological resources. As a whole, this body of work represents a transdisciplinary approach to resilience analysis. By integrating socioecological theory, economic modelling, and farmer-centred perspectives, it highlights both the strengths and weaknesses of existing resilience methodologies. Rather than favoring a single lens, it demonstrates how different approaches capture different dimensions of resilience and why combining them is essential to obtain a comprehensive understanding of the limits, trade-offs and synergies, and development pathways of small ruminant farming systems.

Using extended lactations to shape resilience of goat farming systems: a modelling approach

C. Descheerder[1,2], O. Martin[2], F. Bidan[1], C. Duvaux-Ponter[2], L. Puillet[2]
[1] IDELE, MNE, 75595 Paris, France, [2] Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 91120 Palaiseau, France

Prolonged and repeated heat waves or the arrival of new vector-borne diseases due to climate change have detrimental effects on livestock farming systems. In dairy goat farms, increased culling due to reproductive failure can lead to a decline in herd size and milk production, therefore resulting in economic losses. Historically, dairy goat farmers were using extended lactations (EL) to manage reproductive failure and keep non-pregnant females in the herd. EL consists in maintaining lactation for 485 days or more without intermediate gestation. Dairy goats are able to produce milk for two years and more, not only with a prolonged persistency but also with a pattern of lactation dynamics showing a rebound in production. This practice in dairy goat herds is increasingly used (more than two-thirds of French goat herds) and now concerns not only females that fail to reproduce, but also females that are intentionally not bred. In heat stress situations leading to potential poor fertility results, using EL can maintain overall and reducing the proportion of goats bred, thus mitigating the impact of poor fertility on the herd. This practice also reduces the number of gestations and thus the risky phase associated for the goats and the number kids to cull. There is currently a lack of knowledge on the role of EL in building resilient dairy goat farming systems. There is a need to quantify the consequences of integrating EL in herd management in both perturbed and unperturbed environmental conditions. It is also essential to determine how EL can be integrated into the production system, in line with the farmer's objectives and management practices, particularly by defining the optimal proportion of goats managed in EL. The objective here was to extend the existing Herd Demography Model (HDM) by integrating the management events accounting for two types EL and individual phenotypic trajectories (daily milk production and body weight), based on real data obtained from 84 dairy goats in EL at the MoSAR unit. HDM is an individual-based and dynamic model, which allows to simulate daily physiological stage and milk production of each female in a herd, throughout their lifetime. The modularity of the model allows to implement various breeding practices and reproductive performances. EL can be either unvoluntary in case of reproduction failure, or voluntary when a goat is not bred. For this latter case, three methods can be used to choose goats: random draw, best producers in the herd, or best producers among the goats not selected for artificial insemination (AI). The method and goats' proportion in voluntary and unvoluntary EL are used as model inputs. To illustrate how the model enables to assess the role of EL in dairy goat herds' resilience, a case-study representative of a typical French dairy goat farm was simulated over 20 years (289 goats, with 93 replacement does, and a breeding period from September to November). Two contrasting scenarios were compared. The first one was an unperturbed scenario, with high fertility every year (success rates: 80% AI, 90% natural mating (NM)). The second one was a perturbed one, mimicking a heat stress event occurring in the tenth year at the time of reproduction, leading to a drop in fertility (success rates: 30% AI, 50% NM). For both scenarios, four proportions of goats managed in EL were tested: 0%, 20%, 30%, and 40% of the productive herd. The analysis of the output results provides benchmarks to determine to which extent EL enables to maintain herd demography and production following a sharp decline in fertility.

The Aegean sheep breed revisited: Phenotypic description and husbandry characteristics in island flocks of Greece

M. Karatzia[1], I. Bouzalas[1], T. Papadopoulos[1], E. Kanaki[1], A. Lymperopoulos[2], T. Vanikiotis[1], I. Chaligiannis[1], L. Ekateriniadou[1]

[1] Ellinikos Georgikos Organismos-DIMITRA, Thermi, 57001 Thessaloniki, Greece, [2] International Hellenic University, Sindos, 57400 Thessaloniki, Greece

The Aegean sheep breed was once considered one of the most widespread indigenous sheep populations of Greece, traditionally distributed across the islands of the Aegean Sea. Historically described in the literature as the "sheep of the Aegean". The population includes animals from islands such as Samothrace in the north, to Ios in the south, among others. The population was considered to exceed 100,000 breeding ewes in the 1970s. The breed is characterized by strong adaptability to harsh island environments, limited feed resources, and extensive grazing systems, making it particularly suited to Mediterranean pastoral conditions.The ENIPRO project aims to characterize genotypic and phenotypic variation in island sheep populations and to verify the continued existence of the Aegean sheep breed as a distinct genetic population. Within this framework, the present study focuses on the phenotypic description of sheep and management practices Aegean islands' flocks. A total of 43 ewes, originating from flocks located on the islands of Agios Efstratios, Kythnos, Kea, Naxos, Ios, and Sifnos, identified by farmers as belonging to the Aegean sheep breed and maching the description available, were morphologically characterized (mean±SE). Ewes were on average on their 5th lactation (5.04±1.266), with mean prolificacy of 1.46±0.418 lambs per ewe and mean Body Condition Score of almost 2 (1.93±0.418). In terms of ear size, which is described as one of the most distinctive characteristics of the Aegean breed, most animals' ears were horizontal and of noticeable small size, with a mean length of 11.38±0.48 cm and mean width of 6.85±0.382 cm. Head shape was predominantly narrow, of medium size (mean width of 13.83±0.566 cm and length of 25.28±0.469 cm) with a straight profile. Tails were semi fat with an average length of 33.69±2.573 cm. Mean body length was 61.35±1.18 cm and height at withers reached 68.33±1.04 cm. Most of the evaluated ewes were polled (79.06%), while the average horn length for the horned ones was 39.17±4.894 cm. Regarding fleece characteristics, all animals had coarse, white wool and only 18.60% were covered in the abdominal region. Black or brown spots on the head, ears, muzzle, legs and hoofs were observed in all ewes. Skin pigmentation was evenly distributed, with 50% of the ewes exhibiting pink skin and 50% black skin. The udder was cylindrical and well-formed in all animals and the teats were pointing slightly forward, which was recognized by farmers as the most desirable type for suckling. From a husbandry perspective, most farms were small (45-60 animals) to medium (100-150 animals), with Agios Efstratios flocks beeing the only exception with an average size of 638 animals. All farms were family-operated and low-input, relied on limited natural grazing resources, seasonal pasture use and were supplemented with imported concentrates. Limited use of mechanical equipment and intensive housing facilities were highlighted, in consistence to island pastoral systems. Few major health issues, such as mastitis and diarrhea in lambs were reported, reflecting the resilience of the animals under semi-extensive management. These adaptive traits, combined with satisfactory annual flock milk production (mean of 13.068±1.336,61 tn) and reproductive performance under low-input systems, indicate the potential role of such a breed in sustaining traditional sheep farming in the insular agroecosystems of Greece. This research is implemented under the National Recovery and Resilience Plan 'Greece 2.0', funded by the European Union – NextGenerationEU.

Role of territorial stakeholders in the management of risks arising from interactions between wildlife and pastoral livestock systems

I. Mokrani[1,2], M. Ockman[1,2], C. Bellanger[1,2], M. Ben Abdellah[1,2], L. Chaland[1,2], H. Debay[1,2], H. Faber[1,2], C. Gauvrit[1,2], E. Ruelle[1,2], A. Vedrine[2], M. Virapin[1,3,4]

[1] University of Clermont Auvergne, Campus des Cézeaux, 24 Av. des Landais, 63170 Aubière, France, [2] VetAgro Sup, 89 avenue de l'Europe, 63370 Lempdes, France, [3] INRAE - VetAgro Sup, UMR 1213 Herbivores, Rte de Theix, 63122 Saint-Genès-Champanelle, France, [4] University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment, Vle dell'Università, 16, 35020 Legnaro PD, Italy

The return and expansion of wildlife in the Alps, particularly large carnivores and large herbivores, are modifying the balance of mountain areas. These developments constitute a major challenge for pastoral systems, which traditionally rely on the extensive use of natural environments and on coexistence between human activities and biodiversity.In this context, interactions between wildlife and livestock farming generate sanitary, social, environmental, and predation risks. The management of these multiple risks relies on institutional and multi-stakeholder governance, placing coexistence-related risk management at the core of pastoral sustainability issues.This study aims to analyze, through the perspectives of the interviewees, how territorial stakeholders intervene in the management of wildlife-related risks within pastoral systems in Europe: the case of the Vanoise National Park in France and the case of the Paneveggio Pale di San Martino Natural Park in Italy. It also seeks to characterize the stakeholders involved in risk management. 33 semi-structured interviews (25 for France, 8 for Italy) and 14 street interviews (only for France) were conducted, using a territorial approach, with a diversity of economic, institutional and social stakeholders, as well as territory users. The analysis of the qualitative data collected follows a thematic approach.Four types of risks (environmental, predation, sanitary, and social) are identified by the interviewees. However, according to the respondents, predation is the dominant risk arising from the interaction between wildlife and pastoralism, with direct and indirect impacts. Nevertheless, economic impacts (direct losses, costs related to herd protection, or modifications of pastoral practices) and psychological impacts (stress, mental burden, questioning of the pastoral system, and farmers' sense of isolation) are strongly emphasized by the respondents. Moreover, the social impact of predation, although indirect, occupies a central place in the discourse: land-use conflicts, misunderstandings between stakeholders, and views of a gap between public policies and on-the-ground realities.Regarding the management of these risks, this work highlights a complex multi-level governance system involving a plurality of stakeholders whose roles sometimes overlap. In addition, the multiplication of levels of intervention leads to confusion regarding the role of each stakeholder, thereby fueling misunderstandings and conflicts.Although management measures are implemented, they are sometimes seen as fragmented, poorly coordinated, and ill-adapted to territorial needs. These views are emphasized by the divergent interests of the various stakeholders, thus reinforcing the difficulties involved in implementing shared solutions. Beyond the current risk management measures currently in place, this study suggests that greater consideration of the social, cultural, and relational dimensions of Human-Nature interactions is necessary. Improving mechanisms for consultation, communication processes, and recognition of local knowledge appears essential to fostering a sustainable and socially acceptable coexistence between pastoralism and wildlife in a context of global change.

Drivers of abandonment risk in autochthonous livestock systems: preliminary results from Castilla-La Mancha.

J. Claros-Zafra[1], J. M. Perea[1], M. A. Cantarero-Aparicio[1], R. Arias[2], J. M. Gallardo[3], E. Angón[1]
[1] Universidad de Córdoba, Producción Animal, Producción Animal - Campus Agroalimentario de Rabanales, 14071 Córdoba, Spain, [2] Regional Institute for Agri-Food and Forestry Research and Development of Castilla-La Mancha (IRIAF), CERSYRA, Avenida del Vino, 10, 13300 Valdepeñas, Spain, [3] Real Federación Española de Asociaciones de Ganado Selecto (RFEAGAS), C/ Castelló, 45, 28001 Madrid, Spain

The conservation of livestock genetic resources is closely linked to the persistence of farmers maintaining purebred breeding systems. However, the European Union is currently experiencing a decline in the number of farms rearing purebred livestock, reflecting ongoing structural transformations in the agricultural sector. Farmers' exit from the system results from a complex interaction of structural, economic, and behavioural factors, making the continuity of breeding activities particularly vulnerable in marginal and extensive production systems. Understanding the drivers of farm abandonment is therefore essential for designing effective strategies aimed at conserving livestock genetic resources and supporting rural The conservation of livestock genetic resources depends on the persistence of farmers maintaining purebred breeding systems. However, the European Union is experiencing a decline in farms rearing purebred livestock due to structural changes in the agricultural sector. Farmers' exit results from structural, economic, and behavioural factors, making breeding activities particularly vulnerable in marginal and extensive systems. Understanding the drivers of abandonment is therefore essential for designing effective conservation and rural development strategies. The results indicated that behavioural and motivational variables play a key role in farmers' intention to abandon purebred livestock farming. In particular, farmers' professional identity was strongly associated with breed conservation and, therefore, with their intention to continue livestock farming. The second most influential factor was the subjective norm, particularly the component related to support from the professional environment, highlighting the important role of institutions and breeders' associations in the conservation of autochthonous livestock breeds. In addition, factors related to the sector's economic expectations, the perceived socio-environmental value of the breed, and the perceived capacity to continue farming activity were also found to be significant. These findings suggest that the decision to abandon purebred breeding goes beyond purely technical or business considerations, highlighting the emotional and professional attachment to the breed, which creates a sense of belonging and commitment that may act as a buffer against rural abandonment. However, this commitment may be weakened by subjective norms that depend directly on the level of support provided by institutions and the professional environment. When the efforts of farmers are not recognised or validated by their professional and social surroundings, the risk of abandonment increases. Therefore, it is essential to design strategies that promote the social and ecosystem value generated by autochthonous breeds in rural territories, thereby reinforcing rural identity and contributing to the prevention of rural abandonment.

Resilience of European Livestock Systems: multi-scale, context-specificity and methodological insights

F. Accatino[1]
[1] INRAE, AgroParisTech, Université Paris-Saclay, UMR SADAPT, 22, place de l'Agronomie, 91120 Palaiseau, France

European livestock farming systems are exposed to multiple and interacting challenges, including climate events, market disruptions, demographic transformations and societal pressures. At the same time, they are not merely food production units; they also generate and depend on ecosystem services, sustain rural livelihoods and support cultural traditions. Resilience can be defined as the capacity of a system to resist, adapt and, when necessary, transform in response to disturbances, in order to continue producing food and other services. Resilience is often relative to particular disturbances and defined objectives (resilience of what to what?). This property manifests differently across levels of analysis (e.g., animal, farm, value chain, landscape, region) and each scale makes some aspects more visible than others. Disturbances may be perceived differently according to the geographic region and livestock system type (e.g., monogastrics vs ruminants). Previous studies have advanced in the comprehension of how to measure and asses resilience using both quantitative and qualitative approaches; yet, the multi-faceted nature or resilience – combined with the complexity of European livestock systems – continues to pose challenges to research and policy-making. The purpose of this presentation is to open questions about methodological challenges in assessing and improving resilience of European livestock systems. Drawing on systematic reviews, the presentation highlights how complexity of farming systems influences the way their resilience can be interpreted and evaluated. A systematic review across French regions, combining expert interviews and grey literature analysis, revealed significant differences in how climate-related stressors are perceived across value chains and territories. For example, monogastric sectors showed strong path-dependencies linked to housing infrastructures not adapted to recent climate events, while ruminant systems were primarily constrained by climatic negative impact forage production and land-use dynamics. A review of academic literature highlighted interactions between food self sufficiency and other factors, such urbanisation, water and land use. Urbanisation reshapes rural labour availability and food demand, while water and land resources are shared across multiple competing sectors. These cross-sectoral dynamics show that livestock resilience cannot be analysed in isolation from broader socio-technical and economic environments. These findings suggest that assessing and improving resilience of European livestock farming systems poses methodological challenges: (i) combining quantitative indicators with qualitative approaches capable of capturing actor perceptions across value chains and in different geographic contexts; (ii) conducting context-specific and value chain–specific analyses (no one-size-fits-all approaches), fostering interdisciplinary collaboration, participatory research and cross-sector integration; (iii) applying multiple scales of analysis for both quantitative and qualitative methods. These insights highlight that assessing and enhancing resilience of European farming systems remains a complex and evolving challenge, requiring continued research, stakeholder engagement and methodological refinement.

INOSYS "farm models": a national living lab to simulate change and explore adaptation pathways in French livestock systems

G. Mathieu[1], D. Sterling[2]
[1] Instiut de l'élevage, 149 rue de Bercy, 75012 Paris, France, [2] Chambre d'agriculture France, 9 avenue Georges V, 75008 Paris, France

European livestock farming systems face increasing uncertainty due to climate change, volatile prices and evolving societal demands, which calls for robust empirical bases to assess resilience and support adaptation strategies. In France, INOSYS "Réseaux d'élevage" is a long-standing farm network that annually follows up about one thousand herbivore farms situated in main production areas and in a large diversity of farming systems. The monitoring feeds a national database (DIAPASON) with harmonised structural, technical, economic, environmental and labour indicators. From these data, more than 250 "farm models" ("cas-types") have been built as consistent, data and human-based representations of frequent farming systems in given regions, each combining land use, herd structure and management, input use, production results, work organisation and multi-performance indicators. These farm models are used as a flexible tool to simulate different types of changes, such as climatic variability (e.g. droughts affecting forage yields and grazing) or economic stress (e.g. changes in feed or energy prices), to quantify impacts on technical results and farm income and to identify room for manoeuvre and feasible technical adaptations. Over the 2021–2027 period, INOSYS has been further extended through 18 thematic networks focusing on specific transition issues, including "Adaptation to climate change", "Feed and protein self-sufficiency" and "Cost-efficient systems", which deepen the analysis of adaptation strategies with groups of volunteer farmers. Beyond biophysical and economic resilience, the device has also produced studies on the transmissibility of farming systems (e.g. for generational renewal), workload and the attractiveness of different livestock models, thus linking resilience to farmers' working conditions and willingness to remain in or enter the sector. Overall, INOSYS operates as a national living lab that combines long-term farm monitoring, construction of farm models, change simulations, and thematic co-innovation with farmers and advisers, providing a unique platform to inform policymakers, advisory services and education on the resilience of French livestock farming systems.

Intensive holm oak plantations as a climate adaptation strategy to enhance resilience of traditional Iberian pig production systems

J. García-Gudiño[1,2], A. Ortiz[2], M. Freire[2], J. M. Pérez-Rodríguez[2], A. I. Del Rosario[2], L. León[2], D. Tejerina[2]
[1] University of Extremadura, Animal Production and Food Science, Avenida de la Universidad, 10003 Cáceres, Spain, [2] Centre of Scientific and Technological Research of Extremadura, A-V km 372, 06187 Guadajira, Spain

Interannual variability in natural acorn production has always been a characteristic feature of the dehesa ecosystem, but climate change is intensifying this variability, increasingly challenging the natural resource-based fattening of Iberian pigs during the montanera phase. The Spanish Quality Standard for Iberian pig production requires animals to achieve a minimum weight gain of 46 kg during this phase, feeding exclusively on natural resources from the dehesa ecosystem, to qualify for the acorn category. When acorn availability at the end of the fattening period is insufficient for all animals, some fail to meet this requirement and must be reclassified into categories with lower market value. This reclassification represents a 23% reduction in price per kilogram of live weight, translating to substantial economic losses for producers. This study evaluated whether acorns from intensively managed and irrigated holm oak (Quercus ilex) plantations could provide a complementary resource when natural acorn availability is insufficient, enabling at-risk animals to meet quality standard requirements whilst maintaining production characteristics. A total of 85 purebred Iberian Retinto pigs entered the montanera finishing phase under traditional conditions. After 48 days, 10 animals that were not on track to meet the minimum requirements (weight gain 41.05 ± 0.50 kg; body weight 143.2 ± 1.98 kg) and 10 animals showing adequate progress (weight gain 46.5 ± 0.67 kg; body weight 147.3 ± 1.11 kg) were selected for the study. The underperforming group was supplemented with 10 kg/day of acorns from intensive plantations (established in 2018, average yield 1,500 kg/ha under drip irrigation), whilst the adequate-growth group continued under traditional montanera as controls. Both groups completed the same 63-day finishing period at identical stocking density (0.75 pigs/ha). Acorns from intensive plantations showed comparable nutritional composition to natural acorns. The underperforming group, initially at risk of not achieving the minimum requirement, exhibited significantly higher average daily gain during the final 15-day period following supplementation (1.347 vs 1.224 kg/d; P=0.001), successfully meeting the required 46 kg weight gain and avoiding disqualification. Final live weights were comparable between groups (163.4 vs 165.7 kg; P=0.625). At slaughter, carcass characteristics including weight, yield, backfat thickness, length, and prime cut yields showed no significant differences (P>0.05), demonstrating that supplementation maintained normal carcass development and commercial value. This approach prevented reclassification of all supplemented animals, avoiding economic losses equivalent to 23% of animal value, which represents a critical difference for farm economic viability. Importantly, this strategy is designed as a complementary support tool implemented only during years of insufficient natural acorn production and targeted specifically at animals at risk of disqualification. In conclusion, acorns from intensive holm oak plantations provide a practical climate adaptation strategy that enhances the resilience of traditional extensive livestock farming systems. This approach enables producers to cope with increasing climate variability whilst preserving the authenticity and sustainability of dehesa-based Iberian pig production, contributing to the long-term viability of this valuable cultural and ecological heritage system.

Multidimensional information system for zootechnics: the case study of buffalo farm and the dark side of outsourcing drivers

D. Vecchio[1], M. Serrapica[1], G. Di Vuolo[1,3], G. Cappelli[1], V. Lorenzi[2], C. D. Ambra[1], F. Serrapica[5], A. Vastolo[5], G. Rofrano[1], L. J. D'Auria[1], A. Atzori[8], G. Stilwell[4], L. A. De La Cruz Cruz[9], A. Zanella[6], M. Giampietro[7], A. Fierro[5]
[1] IZSM, Via della SAlute, 2, 80055 Portici, Italy, [2] IZSLER, Via Bianchi, 9, 24124 Brescia, Italy, [3] ANASB, Via Petrarca, 81100 Caserta, Italy, [4] FMV-ULIsboa, Av. da Universidade, 1300-477 Lisboa, Portugal, [5] UNINA, Via Mezzocannone, 80138 Napoli, Italy, [6] FMVZ-USP, Av. Duque de Caxias Norte, 13635-900 Pirassununga, Brazil, [7] UAB, Passeig Lluís, 08010 Barcelona, Spain, [8] UNISS, Via De Nicola, 07100 Sassari, Italy, [9] UAM, C. del Hueso, 1100, 04960 Mexico City, Mexico

The sustainability of animal husbandry represents a controversial topic that is often associated with narratives focusing on accusatory arguments. The following contribution illustrates a relational model of animal husbandry which describe the multifunctional value of the sector, by providing a richer representation that allows to study its metabolic criticalities. To achieve this result, we adopt the MultiScale Integrated Accounting of Societal and Ecosystem Metabolism approach, a relational multicriteria framework allowing the characterization and evaluation of different metabolic features of the system. The integrated characterization of the system includes biophysical aspects (matter and energy flows), economic variables (monetary flows and investments), and relevant information for informing animal welfare strategies. The accounting method allows to evaluate the metabolic performance of animal husbandry using 4 criteria: (i) feasibility – looking at the constraints imposed by the ecosphere (both resources availability on the supply side and the ability to receive wastes on the sink side); (ii) viability – looking at the characteristics of techno-economic strategies adopted by the system; (iii) desirability – looking at the normative and institutional practices adopted by the different social actors; (iv) externalization – looking at the level of openness the system determining its dependence on external resources, a dependence translating into environmental and social externalized impacts. The 20 farms surveyed had an average usable agricultural area (UAA) of 25 ha, entirely devoted to forage production. Feed autonomy (FA) was determined as the proportion of self-produced DM consumed relative to the total DM intake at the herd level. Additionally, energy feed autonomy (FAe) and protein feed autonomy (FAp) were calculated by multiplying the amount of consumed DM by its energy and crude protein content for both purchased and self-produced feeds. Maize silage, often grown in rotation with winter grasses – either as pure crops or in legume mixtures – is the predominant forage. Regarding herd composition, an average of 337 (±188) animals was recorded per farm, including 116 (±74) young females and 213 (±122) adult females. The average milk yield per cow was 2.395 ± 275 kg. Consequently, the average stocking rate was 19±17 heads per h of UAA. In terms of feeding practices, 35% of farms relied exclusively on hay as their forage source, while the remaining farms used varying proportions of maize silage and hay. Compared to herd requirements, 85% of the forage and 100% of the straw and concentrate feed were purchased externally. As a result, the average FA level was estimated at 15%, ranging from 2.5% in dry herds to 23% in lactating herds. Expressed in terms of consumed energy and protein, FAe was 14%, while FAp was slightly lower at 12%. Our preliminary findings reveal a significant dependence on off-farm feed in dairy buffalo farming, with limited forage self-sufficiency and high stocking densities, indicating that scarce arable land is a major challenge to economic and environmental sustainability.

Supply chain vulnerability in protein reduced poultry nutrition: A scenario approach to amino acid supply disruption in broiler production

J. Gickel[1], C. Visscher[1,2]
[1] University of Veterinary Medicine Hannover, Science for innovative and sustainable poultry farming, Bünteweg 13, 30559 Hannover, Germany, [2] University of Veterinary Medicine Hannover, Institute for Animal Nutrition, Bischofsholer Damm 15, 30173 Hannover, Germany

Modern protein reduced broiler nutrition relies on globally sourced industrial amino acids (AA) to formulate balanced diets. This structural dependency creates vulnerability within poultry supply chains. Temporary AA shortages may force feed mills to reformulate diets with lower levels of synthetic AA or even without it, increasing crude protein supply, worsening amino acid balance, and impairing feed efficiency. A scenario was developed to explore the systemic implications of such a disruption for Germany. The reference system represents Ross 308 broilers with a 37-day fattening period and a final liveweight of 2.3 kg. Annual production volumes were derived from national slaughter statistics (631 million broiler chickens) and feed production data (6.5 million tonnes of poultry feed per year; 42% allocated to broilers). The scenario assumes that all feed mills in Germany react similarly to reduced AA availability by reformulating the third feeding phase (grower 2; day 21–30) without synthetic AA. To maintain an approximately adequate supply of essential AA, crude protein levels are increased through a higher proportion of rapeseed meal (RSM) in the formulation. Potential negative performance effects in this phase are represented as feed conversion ratio (FCR) penalties of +2%, +5%, and +10% relative to the standard formulation. To determine the duration of AA shortage required to exert a relevant impact on the RSM market, additional demand corresponding to 1% ("noticeable") and 2% ("considerable") of total annual German RSM use was calculated based on the daily additional demand. Environmental impacts (acidification, climate change, and freshwater eutrophication) were assessed using life cycle assessment (LCA) according to the Environmental Footprint (EF) 3.1 method, including changes in nitrogen excretion resulting from altered protein supply. To determine annual system-level impacts, impact factors per kg liveweight were scaled to the annual affected liveweight mass in German and compared to the reference production. Under the baseline scenario (+5% FCR), additional RSM demand reaches 1% of the annual market after 64 days of disruption and 2% after 129 days. Under a lower performance penalty (+2% FCR), the same thresholds are reached later (67 and 135 days), whereas under a severe penalty (+10% FCR) the 1% and 2% thresholds are reached substantially earlier (60 and 120 days). At the 1% threshold (64 days), annualized system changes amount to +591 kmol H□ eq (acidification), +2,453 t CO_2 eq (climate change), and +5 t P eq (freshwater eutrophication), corresponding to +1.3%, +0.1%, and +0.5% relative to the national baseline. At the 2% threshold (129 days), impacts increase to +1,192 kmol H□ eq, +4,944 t CO_2 eq, and +10 t P eq (+2.6%, +0.2%, and +1.1%, respectively). Acidification and eutrophication increase consistently with higher protein supply and nitrogen excretion, whereas climate change shows comparatively smaller relative system-level changes indicating a higher resilience of this factor to short-term protein-driven feed reformulation. The findings illustrate a measurable supply chain vulnerability in poultry nutrition and highlight the structural coupling between nutritional formulation, feed raw material markets, and environmental outcomes in broiler chicken systems. Strengthening the resilience of poultry nutrition to the scenario of AA shortage may include the diversification of AA sourcing and the establishment of a responsive approach that considers all possible outcomes.

Building a resilient dairy-beef calf: Integrating genetics, early-life management, and producer decision-making

D. Renaud[1]
[1] *University of Guelph, 50 Stone Rd E, N1S2W1 Guelph, Canada*

The global expansion of beef production within dairy systems has resulted in a growing population of dairy-beef calves transitioning from dairy farms to specialized rearing and fattening operations. These calves represent a biologically vulnerable population, and their early-life management and genetic background have profound implications for subsequent health, welfare, and performance. Although transport and commingling are frequently highlighted as critical risk periods, resilience at the time of movement is largely shaped by decisions made during the first days and weeks of life, including breeding strategy and neonatal care. This presentation synthesizes current knowledge on how early-life management and genetic selection influence downstream outcomes in dairy-beef calves. Particular attention will be given to colostrum management and adequacy of passive immunity, early life nutritional strategies, age at transportation, housing conditions, and identification of calves following transport that are at elevated risk for disease. Inadequate transfer of passive immunity and suboptimal neonatal nutrition impair immune competence and growth, increasing susceptibility to enteric and respiratory disease and reducing adaptive capacity following movement. Breeding decisions further influence birth weight, vigor, growth potential, and disease resilience, thereby modifying how calves respond to early-life stressors and environmental challenges. Outcomes in dairy-beef calves are shaped not only by biological determinants but also by human decision-making. Emerging evidence indicates that care of calves destined to be raised off the dairy farm is influenced by economic incentives and perceived ethical obligation, contributing to heterogeneity in early-life management. Addressing these structural and behavioural drivers is necessary to achieve consistent improvements in calf health and welfare. Sustainable progress in dairy-beef systems depends on integrating breeding decisions, early-life management, and producer incentives within a coordinated cross-sector approach that builds biological resilience before calves leave the dairy farm.

Early group housing of female dairy calves: first results of the COLOCAVO project

D. Fouvez[1], G. Trou[1], C. Roy[2], L. Oble[2], F. Lepeltier[3], V. Lollivier[4], F. Crepel[4], M. Le Guenic[1], M. Vimont[5], C. Hardy[5], L. Mirabito[5]

[1] Chambre d'agriculture de Bretagne, Rue Maurice Le Lannou, 35042 Rennes, France, [2] Ferme expérimentale laitière des Trinottières, La Futaie, 49140 Montreuil sur Loir, France, [3] Ferme expérimentale de Normandie, La Blanche Maison, 50880 Pont Hebert, France, [4] INRAE, Pegase, 35590 Saint-Gilles, France, [5] Idele, 149 Rue de Bercy, 75012 Paris, France

The COLOCAVO project aims to generate robust reference data on group housing of dairy calves from the first week of life and to identify practical technical pathways that can be implemented on commercial farms. A participatory action-research design was implemented in four experimental farms (1 Les Trinottières, 2 Trévarez, 3 La Blanche Maison and 4 INRAE-IEPL). According to its own initial situation regarding group housing of calves, each farm implement and test some possible modification. The general objective was to have an oveview of group housing in the four different situations. The first iteration was conducted between September 2024 and September 2025. Across the four farms, calves (Prim' Holstein in three farms and Normande in one) were housed, either from birth or from one week of age depending on the facilities, in groups of 2 to 9 calves. The experimental factors were : 1 pair housing and group stability vs instability (to evaluate the effect of mixing when calves were transfered in groups of 6 at 4 weeks of age), 2 milk-feeding frequency (one feeding vs two to reduce cross-suckling), 3 environmental enrichment using non-nutritive teats vs no enrichment (to reduce cross-suckling) and 4 milk delivery method (to test the use of collective feeder). Calves were fed : 1 bucket, 250 L in 8 weeks, concentrate and straw 2 Collective feeder with teats, 450-500 L fermented milk in 8 weeks, hay+cereal+protein crops 3 bucket with teat, 350 L in 9 weeks, concentrate+hay 4 Milkbar, 500 L in 9 weeks, concentrate and straw. Measurement protocols were harmonized across the four sites. Calves were weighed at minimum at birth, weaning, and 6 months of age. Health events (morbidity and mortality) were recorded throughout the trial. Behaviour was assessed on all farms around milk-feeding events and at mid-day at different calf ages, using video recordings or direct observations followed by scan sampling (animals observed at fixed time intervals) with a shared ethogram. Calf growth rates met the target objectives in all four farms, and the tested practices did not affect growth. Mortality and morbidity were very low, null in some cases, under our experimental conditions. Behavioural monitoring identified common patterns across farms. Resting was the predominant behaviour, accounting for 39–69% of the observation period during the first five weeks of life. Feeding behaviour was the second most frequent activity (13–26% of the observation period). Interactions with the environment—when calves licked, sucked, or sniffed elements of the pen (e.g., barriers, feeding rails, walls, or hutches)—represented 4–19% of the time, depending on the farm and housing conditions. Behavioural changes with age were similar across the four farms, with a gradual decrease in resting and a corresponding increase in feeding-related behaviours from an average age of three weeks. Cross-sucking between calves, mainly observed around milk distribution, remained infrequent (1–7% of the observation period). When this behaviour occurred, we hypothesized that it may be associated with the feeding system and/or changes in housing and these hypothesizes will be tested during the second experimental iteration of the project. In conclusion, these results represent initial reference data in the French condition and generated hypotheses that should be confirmed and refined in subsequent iterations.

Is increasing pellet diameter an effective strategy to achieve the withdrawal of straw (forage) in the fattening of crossbred dairy beef calves under straw (forage) scarcity?

L. Llonch[1], S. Marti[1], A. Solé[1], J. Riera[2], C. Medinyà[3], J. Cucurull[4], M. Devant[1]
[1] IRTA, Ruminant production, Torre Marimon, Caldes de Montbui, 08140 Barcelona, Spain, [2] NANTA, S.A., Tres Cantos, 28760 Madrid, Spain, [3] SINUAL, Sallent, 08650 Barcelona, Spain, [4] Grup BonÀrea, Guissona, 25210 Lleida, Spain

The increasing scarcity and year-to-year variability in straw availability driven by climate change are prompting the search for alternative forage strategies for fattening bulls fed high-concentrate diets. We hypothesized that increasing concentrate pellet diameter may stimulate chewing activity and, consequently, rumination, thereby partially mimicking the functional role of straw as a forage in preventing digestive disorders such as bloat or rumen acidosis. If increasing pellet diameter can stimulate rumination to a similar extent as the ad libitum provision of non-chopped straw, pellet enlargement could represent a suitable strategy to promote rumination during periods of straw (forage) scarcity. Nineteen recently weaned crossbred dairy beef bull calves (98 ± 1.9 kg of BW; 75 ± 2.7 days of age) were individually housed in hutches with sawdust bedding on a concrete floor at a commercial farm in Montgai (Lleida, Spain) during April 2025. Calves were assigned to one of four treatments combining concentrate pellet diameter (3.5 vs. 8 mm) and non-chopped wheat straw provision (yes/no): 1) 3.5+S (n = 5), 3.5 mm pellet with straw; 2) 3.5 (n = 5), 3.5 mm pellet without straw; 3) 8+S (n = 4), 8 mm pellet with straw; and 4) 8 (n = 5), 8 mm pellet without straw. Feed (concentrate and straw, offered in separate feeders) and water were supplied ad libitum. The trial lasted 14 days. Body weight was recorded at the beginning and end of the study. Individual daily intake of concentrate, straw, and water was measured, and health status, including bloat and fecal scores, was monitored. Data were analyzed using a mixed-effects model including treatment, day, and their interaction as fixed effects, with initial BW as a covariate, and with day as a repeated measure. A significant treatment effect was observed for concentrate intake ($P < 0.01$; 2.70_b, 2.16_c, 3.11_a, and 2.40_{bc} ± 0.192 kg DM/day for 3.5+S, 3.5, 8+S, and 8, respectively). Also, a tendency for treatment by day interaction ($P = 0.09$) was detected, with similar concentrate intake across treatments on day 1, followed by pattern divergences thereafter. When comparing the straw-fed treatments (3.5+S and 8+S), straw intake was not affected by pellet diameter ($P = 0.59$; 0.29 vs. 0.25 ± 0.060 kg DM/day for 3.5+S, and 8+S, respectively). Straw provision increased water intake independently of pellet diameter ($P = 0.01$; 7.43_a, 5.83_b, 7.50_a, and 5.60_b ± 0.649 L/day for 3.5+S, 3.5, 8+S, and 8, respectively). No treatment differences were detected for bloat or fecal scores. In conclusion, straw provision enhanced total feed intake in crossbred dairy beef calves. Among calves provided with straw, 8 mm pellet stimulated higher concentrate intake than conventional 3.5 mm pellet. Moreover, in the absence of straw, 8 mm pellet maintained concentrate intake at levels similar to 3.5 mm pellet with straw. These preliminary results suggest that feeding calves with 8 mm pellet without straw may help sustain concentrate intake during periods of straw (forage) scarcity. Rumination data and long-term studies will further clarify the potential of pellet diameter enlargement as a forage-replacement strategy.

Grass-based or maize-based TMR for young bulls have similar effects on growth and carcass quality but different effects on health

M. Vestergaard[1,2], M. L. Petersen[2], A. M. H. Kjeldsen[2], N. B. Kristensen[1]
[1] Aarhus University, Foulum, 8830 Tjele, Denmark, [2] SEGES Innovation, Skejby, 8200 Aarhus N, Denmark

Two differently composed TMRs were simultaneously compared in an on-farm trial with young bulls slaughtered at 10 months of age. A grass-based TMR (G) with grass silage as the main forage part was compared with a maize-based TMR (M) with snaplage as the main forage source. The two TMRs were prepared fresh daily and fed once daily at a 4.5 m feedbunk area in front of each pen. M consisted of 40% snaplage, G consisted of 28 to 35% 1st and 2nd cut grass silage. The TMRs also included barley, rye, sugar beet pellets and vitamins and mineral mixtures. Based on bi-weekly feed analyses, DM (%), CP, starch, NDF, ash (all g/kg DM), net Energy (SFU/kg DM) were 63, 143, 367, 247, 56 and 1.05 for M and 67, 147, 357, 255, 59, and 1.04 for G. Total feed allowance were recorded for each TMR daily. A total of 2 x 180 male calves, 1/3 Holstein and 2/3 Belgian Blue x Holstein calves were enrolled. Mean age and live weight at start was 130 d and 183 kg for G and 132 d and 182 kg for M. Calves were housed in mixed order in 12 adjacent pens in a straw-bedded finishing barn. Data was analyzed using linear mixed models in R with pen as the statistical unit. DMI was 7.7 and 7.6 kg DM/d, ADG 1.44 and 1.39 kg/d, and FCR 5.66 and 5.62 SFU/kg ADG for M and G, respectively. No statistical differences were found regarding performance data. At the mean age of 315 d, calves were slaughtered pen-wise. Mean carcass weight (234 kg), carcass gain (681 g/d), and EUROP conformation (5.6) did not differ between TMRs. However, more carcasses from G (21%) reached EUROP fatness of 3 compared with M (8%). Furthermore, slaughter remarks related to lungs, liver and total remarks were significantly lower for G than M. The relatively low liver abscess frequency (6.5 and 4.8% for M and G, respectively) suggests that both TMRs produced a similar rumen health. Based on this trial, it is possible to include grass silage instead of the commonly used snaplage in a TMR for fast growing bull calves and obtain similar performance and carcass quality.

Reduction of stocking density during the transport of finishing dairy beef calves to the slaughterhouse: truck thermal microclimate and calves' stress indicators

A. Martín[1], N. Naranjo[1], M. Devant[1], M. Herskin[3], Z. Chen[2], T. Norton[2], S. Martí[1]
[1] Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Ruminant Production, Carretera C-59, Km. 12,1, 08140 Caldes de Montbui, Spain, [2] Catholic University of Leuven, Department of Biosystems, Kasteelpark Arenberg 30, 3001 Heverlee, Belgium, [3] Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, DK8830 Tjele, Denmark

The transport of live animals is a critical stage in the beef production chain, during which animal welfare can be compromised by multiple factors, particularly environmental conditions. Exposure to high ambient temperatures can alter the microclimate inside the vehicle, increasing the risk of heat stress and compromising cattle welfare. Therefore, it is essential to understand how ambient temperature and stocking density influence internal truck temperature, the thermal environment to which cattle are exposed, and its impact on their welfare. The objective of this study was to evaluate the thermal conditions inside a livestock trailer under different stocking density scenarios while also assessing their impact on animal welfare. Two simultaneous journeys were conducted using two identical trucks along the same route: one with high density (HD; 38 animals, 1.57 m²/animal) and one with low density (LD; 32 animals, 1.88 m²/animal), corresponding to a reduction of one animal per compartment in the LD treatment. The 350 km journey of 5 h 20 min was carried out from a commercial feedlot in the province of Lleida to a slaughterhouse in Valencia, Spain, during August under high ambient temperatures (HT; mean 32.5 °C; maximum 36 °C; minimum 29.5 °C). Animals were crossbred dairy beef bulls with an average live weight of 559 ± 35.9 kg and 350 ± 9.7 days of age. Transport was performed using a two-deck trailer divided into six compartments. Internal and external temperatures were recorded using iButton sensors (DS1923, iButton®, USA). Each compartment contained four sensors (one in each lateral and two in the roof) and sensors attached to the ear tags of three animals to record temperature at animal height. External ambient temperature was recorded using sensors mounted on both side mirrors of each truck. All animals were weighed, and blood samples were collected to assess oxidative stress parameters (serum ROS, TBARS, and lactate) two days before transport and immediately after slaughter. Following slaughter, carcass pH and dressing percentage were measured. Statistical analyses were conducted in R using lmer. Data was separated in three stages: before resting time, during resting inside the truck, and after resting. Stocking density was included as a fixed effect and compartment as a random effect; baseline values for oxidative stress (two days pre-loading) were added as covariates. No differences were observed in internal truck temperatures between the two densities while the trucks were in motion (average of 32.5 vs 32.9 °C for HD vs LD trucks during the total journey). However, while stationary, the HD truck tended to have higher temperatures at the ceiling level compared with the LD truck (AUC 1.13 vs 1.08 for HD vs LD; P = 0.06). When temperature at animal level was evaluated, the higher ceiling temperature was not observed at animal level (1.36 vs 1.34 of AUC for HD vs LD; P = 0.13). The truck density evaluated herein did not affect serum oxidative stress parameters or carcass pH. In summary, during periods of high ambient temperatures, reducing stocking density by 16% had minimal effects on the truck's internal environment and did not positively impact oxidative stress indicators or carcass parameters.

Transport of unweaned calves: risk factors and future perspectives

S. Marti[1], F. Marcato[2]
[1] IRTA, Ruminant Production, Torre Marimon, 08140 Caldes de Montbui, Spain, [2] Wageningen Livestock Research, Animal Health & Welfare, De Elst 1, 6808 WD Wageningen, Netherlands

The veal and dairy beef sectors are important outlets for surplus calves originating from the dairy industry. The welfare of these calves is a major concern as the animals faces many challenges in the early stages of their life. Among these challenges, transportation is a major player with regard to calf health and welfare. During their production life, calves are moved at a young age from their dairy farms of origin to assembly centres and subsequently to veal or rearing farms. Then calves are transported again at the end of the fattening period to the slaughter house. Transportation includes multiple stressors and critical factors such as handling, commingling with unfamiliar animals, exposure to new environments, food and water deprivation, and thermal stress. Moreover, the first transport moments occurs when animals are young and in their immunity gap period, which makes them more vulnerable to different pathogens. Thus, the combination of all these factors lead to a higher the morbidity and mortality rates in the first weeks post-transport. As a result of the high prevalence of clinical signs (especially related to respiratory and gastrointestinal disorders) there might be a higher use of antimicrobials at the rearing farms, which is a major problem faced by the sector. This presentation will address the most critical factors around transport and their impact on health and welfare of calves, and will provide an overview of future perspectives to improve conditions of surplus calves.

Comparison of organ development at arrival in transported dairy beef calves from two origins: multi origin marketed calves and calves sourced directly from proximity dairy farm

C. J. García Vázquez[1], M. Devant[1], S. Marti[1]
[1] IRTA, Ruminant Productio, Torre Marimon, 08140 Caldes de montbui, Spain

Marketing, handling, and transportation of unweaned dairy beef calves negatively affect their feed intake recovery and growth, which aligns with the energy deficit and impaired gastrointestinal function typically observed upon arrival at the farm. To develop effective—primarily nutritional—recovery strategies, a deeper understanding of how this commercialization process influences gut and other metabolically relevant organs like liver, thymus, heart and lungs development is required. For this reason, two distinctly different commercialization pathways were compared: multi-origin marketed calves (MO), which experience several transport events and temporary stays in concentration centers—exposing them to stress from loading, unloading, mixing, and variations in both original and center-specific nutritional programs, and proximity-sourced calves, collected directly from nearby dairy farms (DIR), which are not mixed with animals from other origins and share the same initial nutritional program. To conduct this study, a total of 48 calves were used (age between 14 and 30 days). 24 calves of the 48, arrived after being marketed and transported from Germany (MO; initial BW = 60.9 ± 3.02 kg); the other 24 calves were proximity calves that arrived directly from a close dairy farm (< 100 km) (DIR; initial BW = 42.6 ± 3.02 kg). Each group of calves entered at the rearing farm in two batches separated 3 weeks a part. Upon arrival BW and ultrasound score for each calf was recorded to be distributed to be euthanatized in 3 different days (8 calves/treatment/day): d0 after arrival, d7 and d28 to evaluate the digestive tract development. Calves were allocated in collective pens (2 pens/treatment) equipped with an automatic feeder. Calves were fed 2 L of milk replacer twice daily (125 g/L) and ad libitum concentrate feed but were fasted overnight before killing. In the present abstract preliminary data describing the gut empty weight of different sections (rumen, omasum, abomasum, duodenum, jejunum, ileum, cecum, colon) and liver, thymus, heart, and lungs will be described. Data were analyzed using a mixed-effects model including treatment, day, and their interaction as fixed effects, with initial BW as a covariate. Rumen weight tended (P = 0.09) to be smaller in the DIR calves compared with the MO calves throughout the study (227, 225, 744, and 441, 431, 916 g ± 9.61 for d0, d7, and d28, respectively); however this tendency (P =0.11) changed when corrected by BW (0.70, 0.67, 1.29, and 0.53, 0.50, 1.17 ± 0.128 % for d0, d7, and d28, respectively). Abomasum weight corrected by BW was lesser (P = 0.05) in DIR compared with MO calves (0.63, 0.67, 0.62, and 0.73, 0.76, 0.70 % ± 0.0418 for d0, d7, and d28, respectively); contrary duodenum weight tended (P = 0.10) to be greater in DIR than in MO calves (0.15, 0.28, 0.30, and 0.12, 0.17, 0.26 ± 0.494 g for d0, d7, and d28, respectively). Colon weight corrected by BW tended (P = 0.09) to be greater in DIR than in MO calves (0.78, 0.95, 1.20, and 0.79, 0.80, 0.94 ± 0.10 %, for d0, d7, and d28, respectively). Liver weight tended (P = 0.09) to decrease in DIR compared with MO animals where liver weight tended to increase with days after arrival (2.36, 2.12, 2.18, and 1.94, 2.38, 2.32 ± 0.184 kg for d0, d7, and d28, respectively). These preliminary data suggest that where calves originate may influence their organ development and recovery upon arrival at the rearing farm. Ongoing analyses (enzyme activity, microbiota, gene expression, and total gastrointestinal permeability) will add to this information and help design nutritional strategies to improve recovery and welfare.

Nutritional strategy combining sensory additives and olive bioactives enhances post-transport recovery of dairy beef calves with pneumonia

A. Martín[1], M. Blanch[2], M. Devant[1], S. Martí[1]
[1] Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Ruminant Production, Torre Marimon Carretera C-59, Km. 12,1., 08140 Caldes de Montbui, Spain, [2] Lucta, S.A., Innovation Division, Av de Can Domènech s/n, 08193 Bellaterra, Spain

Marketing and transportation impair health and welfare of unweaned dairy beef calves, and it is more critical when calves are transported with pneumonia, as their feed intake is low. Previous studies have shown that the use of additives to enhance intake and immunity could help to recover calves after the negative effects of stress, feed restriction and fasting suffered during marketing and transportation. A total of 62 calves (65.7 ± 4.37 kg BW and 35.2 ± 3.84 d of age) with pneumonia (ultrasound score ³ 3) arriving at a commercial farm after marketing and transportation were used to evaluate the effect of mixture of feed additives (FA: comprising palatability enhancers, olive bioactives, and tributyrin) added to the concentrate feed on performance and ultrasound lung score until 1 weeks after weaning. Calves were fed 2 L of milk replacer (MR; 12.5% solids) twice daily from d1 to d21, and on d 21 of the study, calves were partially weaned and only milk replacer was offered in the morning, and on d 28 all calves were completely weaned. Calves had ad libitum access to concentrate feed throughout the trial. The study lasted 35 days. Calves arrived in 4 batches and were allocated to 2 pens/batch and assigned to one of 2 treatments (4 replicates/treatment): calves fed a concentrate without FA (CONTROL; n=31); calves fed a concentrate containing FA (COMBO; n=31). Calf BW and pen intake were recorded weekly. A lung ultrasonography was performed weekly. All data were analyzed with a mixed-effects model, except for the lung ultrasound data, which were analyzed using a cumulative link mixed model. Average daily gain tended to be greater over the entire experimental period in COMBO calves (P=0.07) compared with CONTROL calves (0.76 vs. 0.67 Kg/d ± 0.065 for COMBO and CONTROL respectively). Body weight showed an interaction of treatment by time (P=0.07), where COMBO calves had greater BW on d21 (81.5 kg vs. 79.0 kg for COMBO and CONTROL; P=0.04) and d35 (93.2 kg vs. 90.5 kg for COMBO and CONTROL; P=0.02) compared to CONTROL group. Moreover, average concentrate intake over the whole period did not differ between COMBO and CONTROL calves (0.786 vs. 0.683 kg/d, respectively) however, during the first 14 days after arrival when calves fed COMBO numerically doubled the concentrate intake compared CONTROL (d1-d7: 125 g/d vs 74 g/d, d8-d14: 435 g/d vs 222 g/d for COMBO and CONTROL, respectively). Lung ultrasound lesions were not affected by the additive throughout the study period, however, numerically the percentage of calves with pneumonia lesions from day 7 to 28 was lesser in COMBO than in CONTROL calves. These results highlight the potential of using sensory additives and olive bioactives to improve the performance of calves with pneumonia at arrival at the rearing farm.

An overview of dairy-calf systems for meat production in north-west Europe

P. Crosson[1], B. Berthelot[2], P. Madrange[2], A. Mertens[3], C. Battheu-Noirfalise[3], E. Henrotte[4], R. Reading[5], R. Riedel[5], F. Kaemena[6], I. Morel[7]

[1] Teagasc, Animal and Grassland Research and Innovation Centre, Grange, C15P93 Dunsany, Ireland, [2] French Livestock Institute, Production and Products, La touche es Bouviers, 56430 Mauron, France, [3] Walloon Agricultural Research Centre, Farming Systems, Rue du Serpont 100, 6800 Libramont, Belgium, [4] Eleveo, Innovation, Rue des Champs Elysées 4, 5590 Ciney, Belgium, [5] Convis, Advisory, Zac 4, 9085 Ettelbruck, Luxembourg, [6] Chamber of Agriculture of Lower Saxony, Grassland and Forage Production, Mars-la-Tour-Straße 13, 26121 Oldenburg, Germany, [7] Agroscope, Ruminant Nutrition and Emissions, Tioleyre 4, 1725 Posieux, Switzerland

The objective of 'Better-Calf', an Interreg North-West Europe (NWE) funded project, is to support rural territories and family farms by encouraging adoption of grass-based dairy calf systems. This paper will provide an overview of the first task on the Better-Calf project; to review current meat production systems using dairy calves in NWE. In all regions represented in this project, Holstein-Friesian is the main dairy cow breed ranging from ~95% to ~50% of total dairy cows in Ireland and Switzerland, respectively. The next most important dairy breeds tend to be dual-purpose breeds more traditionally associated with the respective regions. For example, Montbeliarde and Normande in France, Brown Swiss in Switzerland and Fleckvieh-Simmental in Germany. Crossbreeding dairy cows with beef sires to improve the meat production potential of progeny has increased with the greater availability and use of sexed semen being a key factor in this regard. For example, the use of sexed semen in Swiss dairy herds reached nearly 60% in 2024. In France, beef crossbreeds increased from 15% in 2014 to 27% in 2024. In Ireland, 63% of calves born in the dairy herd in 2025 were beef crossbreds. The main beef breeds used differ greatly with Ireland favouring early-maturing breed types, Switzerland mainly using Limousin and Belgium focusing on the Belgian Blue breed. Systems of meat production range from intensive veal units to more extensive pasture-based beef systems. In Ireland, pasture-based dairy-beef systems predominate contributing 60% of prime cattle throughput. Live export of calves for veal production is also an important market. The contribution of dairy-beef to total beef output in France is lower at ~16% with veal production being the main system for dairy calves accounting for almost 60% of the total. Dairy-beef systems are based on indoor systems for bull beef or pasture-based finishing in the case of steer beef. In Wallonia, dairy calf numbers increased by approximately 30% between 2010 and 2024. Almost all dairy calves bred for meat production are raised in veal systems. The production system is quite integrated with a small number of large companies controlling the production chain. In Switzerland, 45% of dairy calves are raised in veal production systems, 20% are fattened intensively as young bulls, and the rest are raised as heifers and steers in more extensive grass-based systems. Holstein male calves in Germany are mainly finished as young bulls with a large proportion exported for veal production. Progeny from dual-purpose cows, such as Fleckvieh, have greater merit for meat production in either veal or beef production systems. Dairy calves in Luxembourg, excluding heifers needed to replace cull dairy cows, are mainly used for meat production in veal production systems. There are a number of common elements to the development of the dairy-calf meat sector across NWE regions. These include a greater focus on beef-on-dairy, increasing the proportion of forage/grazing in the feed budget and reducing the environmental impact of dairy-beef, mainly in the context of greenhouse gas emissions.

Who Is Willing to Compromise? Consumer Clusters, Societal Acceptance of Alternative Housing Systems and Trade-Offs in German Beef Cattle Production

F. Von Steimker[1], E. Bayer[1], S. Kühl[2]
[1] University of Göttingen, Marketing for Food and Agricultural Products, Platz der Göttinger Sieben 5, 37073 Göttingen, Germany, [2] University of Applied Sciences Weihenstephan-Triesdorf, Agricultural Marketing, Am Staudengarten 1, 85354 Freising, Germany

BackgroundPasture-based beef production is widely perceived as the most animal-friendly housing systemin Germany, yet remains uncommon in practice due to challenges related to land availabilityand occupational safety. Consequently, pasture-based systems are currently implementedmainly with steers and female animals. Against this background, alternative housing systemsare discussed as potential compromises between societal expectations, animal welfare, worksafety, and structural constraints.ObjectivesThis study investigates (1) societal acceptance of different beef cattle housing systems, (2)public evaluations of key trade-offs in beef production between animal welfare, occupationalsafety, and land availability, and (3) consumer groups differing in their willingness to acceptcompromise solutions relative to pasture-based systems.MethodsData were collected via an online survey in Germany in March and May 2024, applying quotasfor age, gender, and education. After data cleaning, the final sample comprised 965 participants.Respondents evaluated six beef cattle housing systems presented through images and shortdescriptions in randomized order. For each system, overall acceptance and perceived suitabilityas a compromise relative to year-round pasture-based fattening (pasture in summer, housingwith straw bedding and outdoor run in winter). In addition, two trade-off scenarios wereassessed descriptively: (1) pasture-based fattening with increased safety risks versus castrationunder anesthesia, and (2) indoor housing on fully slatted floors under land constraints versusstraw-based alternatives or technical adaptations.A cluster analysis based on perceived compromise suitability is planned. Cluster solutions willbe determined using dendrogram and elbow criteria, with differences examined via ANOVA,post-hoc tests, and cross-tabulations including socio-demographic variables and attitudestoward animal welfare and meat quality.ResultsPreliminary descriptive results reveal pronounced differences in societal acceptance acrosshousing systems. Fully slatted floor systems are largely rejected, with acceptance rates of 8.9%for concrete slats and 13.2% for rubber-coated slats. Willingness to pay premiums for beef from these systems is similarly low (≤6%). Structural modifications within slatted systems, such asopen-front designs, increase acceptance moderately by 17.8%.Straw-based systems receive substantially higher approval. Housing with straw and open frontis accepted by 59.9%, while systems combining straw bedding with outdoor access reachacceptance levels of 75.3%. The highest approval is observed for pasture-based fattening insummer combined with straw-based housing in winter (85.6%).Regarding compromise suitability, slatted systems are rarely perceived as acceptablealternatives to pasture-based fattening (≈15%), whereas straw-based systems with outdooraccess are widely considered viable compromises (up to 70%).In trade-off scenarios, 52.0% favor pasture-based fattening combined with castration underanesthesia to address safety concerns. In contrast, maintaining slatted housing without pastureaccess is largely rejected; instead, 42.9% support conversion to straw-based systems despitehigher costs. Results of the planned cluster analysis are currently under evaluation.

Comparison of two rearing methods for calves: Effects on weight gain and health during the first four weeks of life

B. Meijer[1], J. Kleist[1], L. Bachmann[1]
[1] University of Applied Science, Faculty of Agriculture and Food Science, Brodaer Str. 2, 17033 Neubrandenburg, Germany

Higher milk intakes and social housing are related to higher body weight gain in calves, as demonstrated in several studies (Welk et al., 2023; Jensen et al., 2015). In some studies, higher milk allowance also resulted in reduced occurrence of disease, but also higher rates of diarrhea were reported (Welk et al., 2023). Social housing supports well-being of calves and is not associated with higher morbidity or mortality (Costa et al., 2016). Hypothesis: The implementation of rearing methods with a higher animal welfare standard for calves is able to improve body weight gain and therefore, could also boost calf health and reduce mortality in dairy practice. Experimental methods: On a dairy farm (950 milking cows), calves were alternately divided in two groups directly after birth: In the control group, calves (n = 69) were tube-fed with 4L colostrum, single-housed and administered with 8L milk/d. In the study group, calves (n = 64) suckled colostrum voluntarily (4.01L), were pair-housed and had a milk allowance of 12L/d. After two weeks, all calves were group-housed but milk allowance remained different. Milk intakes during the first two weeks of life were recorded daily and calves were weighed directly after birth and weekly over the experimental period of four weeks. Treatments according to diarrhea, lung or navel infection or other diseases and mortality were additionally recorded. Statistical analyses: Averaged daily milk intake during the first two weeks as well as body weight gain and treatment frequencies among groups during the first four weeks of life were compared using one-way ANOVA. Results, discussion and conclusion: Social housed calves with higher milk allowance consumed significantly more milk ($P < 0.001$). However, the implementation of more animal welfare related rearing methods did not result in higher weight gain ($P = 0.781$), less treatment rates ($P = 0.551$) or less mortality ($P = 0.18$) during the first four weeks of life. Voluntary intake of colostrum, social housing and higher milk allowance should be mandatory for every calf but improving calf health in dairy practice requires more factors, e.g., hygiene management and vaccination programs, among other things.

Effects of weaning protocols on feed intake and growth performance in calves fed milk replacer ad libitum until 7 weeks of age

A. Stoschus[1], L. E. Diesing[1], T. Nieschulze[2], K. Braun[2], W. Liermann[1], H. M. Hammon[1]
[1] Research Institute for Farm Animal Biology (FBN), Nutrition and Metabolism, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] Holm & Laue GmbH & Co. KG, Moorweg 6, 24784 Westerrönfled, Germany

High milk feeding level in preweaning calves results in low solid feed intake. This can lead to impaired growth during weaning when switching to solid feed, because the forestomach system relies on the intake of sufficient amounts of solid feed for the maturation of forestomach digestion. The objective of this study was to identify weaning protocols for calves with ad libitum milk intake during the preweaning period, ensuring tender transition from milk to solid feed intake to secure sufficient energy and nutrient intake for a steady weight gain through the weaning process. Holstein calves (n=36 female and n=34 male) were supplied with milk replacer (MR; 14 % dry matter) ad libitum by an automatic feeder until wk 7 of age. At wk 8, all calves started with 12 L MR/d. Calves were blocked by body weight (BW) and sex and were assigned randomly to one of 4 different weaning protocols. Groups FAST (n=18) and SLOW (n=17) were weaned linearly either within 3 or 6 weeks. Calves in group CON (n=17) were weaned based on concentrate intake. Further reduction of MR occurred when calves consumed 300 g/d concentrates for 3 days. Additional increase of concentrate intake by 100 g/d led to a reduction of 0.5 L MR/d. Calves in group BWG (n=18) were weaned according to average daily gain (ADG) whereas weekly ADG should remain at > 900 g. BW of the calves was determined at each visit using a scale at the automate, and the MR access was reduced by 200 mL/d if the ADG was kept > 900 g/d. If calves in groups CON and BWG had not been weaned by d 105, they were weaned using a linear programme of the automatic feeder until wk 18. Calves were weighed weekly by hand and ADG was calculated up to wk 20. Calves had free access to water, hay and concentrates all the time and to total mixed ration (TMR) based on grass and corn silage from wk 7 on. Daily MR and concentrate consumptions were measured for each visit by the respective automates. In wk 20, daily TMR intake was measured for each calf. Data were analysed by the Mixed Model of SAS with feeding group, time and sex as fixed effects. MR intake was reduced ($P < 0.05$) in FAST and SLOW as planned. FAST showed lowest ($P < 0.05$) MR intake from wk 9 on. MR intake was lower ($P < 0.05$) in SLOW than in CON from wk 10 to wk 14 and in BWG from wk 11 to wk 13. MR intake was lower ($P < 0.05$) in BWG than in CON from wk 12 to wk 14. Concentrate intake increased ($P < 0.05$) during weaning in all groups. Highest intake ($P < 0.05$) was in FAST in wk 10 and 11 and intake was lower ($P < 0.05$) in CON than in SLOW in wk 13. BW was greater in male than female in wk 7 and the effect remained consistent ($P < 0.05$) during treatments until the end of the study (BW in wk 20: 201.6 ± 1.8 kg (male); 176.7 ± 1.9 kg (female)). In female, FAST had lower BW ($P < 0.01$) than BWG from wk 16 to 20. ADG was higher ($P < 0.05$) in male than female calves (ADG: 1.22 ± 0.01 kg/d for male; 1.04 ± 0.01 kg/d for female). TMR intake in wk 20 was higher ($P < 0.05$) in male than in female calves (TMR intake: 12.8 ± 0.4 kg for male; 11.4 ± 0.4 kg for female). No decline in BW development was observed in any of the treatment groups during the weaning period. Weaning in CON resulted in highest MR and lowest concentrate intake during the weaning process. Ad libitum MR intake led to a significant difference in BW between male and female calves before start of weaning and the difference persisted postweaning. The study was supported by the Federal Ministry of Agriculture, Food and Regional Identity (BMLEH, Bonn, Germany), 22-06.01-28-1-C8.07A-21.

Changes of metabolic traits in blood of dairy calves after ad libitum milk feeding using different weaning protocols

L. E. Diesing[1], A. Stoschus[1], T. Nieschulze[2], K. Braun[2], W. Liermann[1], H. M. Hammon[1]
[1] Research Institute for Farm Animal Biology (FBN), Nutrition and Metabolism, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] Holm & Laue GmbH & Co. KG, Moorweg 6, 24784 Westerrönfeld, Germany

Elevated milk supply enhances anabolic processes and body growth in calves. Metabolic parameters reflect the stimulation of anabolic processes and can function as indicators to identify insufficient nutrient intake during weaning [1]. The objective of the present study was to investigate metabolic changes in ad libitum milk-fed calves during weaning from milk replacer (MR) using four different weaning protocols and to assess parameters that mirror the different weaning protocols. Holstein calves (n=36 female and n=34 male) were supplied with milk replacer (MR; 14 % dry matter) ad libitum by an automatic feeding system until wk 7 of age. At wk 8, all calves started with 12 L MR/d. Calves were blocked by body weight (BW) and sex and were assigned randomly to one of 4 different weaning protocols [2]. Groups FAST (n=18) and SLOW (n=17) were weaned linearly either within 3 or 6 weeks. Calves in group CON (n=17) were weaned based on concentrate intake. Further reduction of MR occurred when calves consumed 300 g/d concentrates for 3 days. Additional increase of concentrate intake by 100 g/d led to a reduction of 0.5 L MR/d. Calves in group BWG (n=18) were weaned according to average daily gain (ADG) whereas weekly ADG should remain at > 900 g. All calves had free access to water, hay and concentrates (wk 2) from first week on and total mixed ration (TMR) based on grass and corn silage from wk 7 on. Plasma concentrations of total protein, albumin, urea, glucose, lactate, beta-hydroxybutyrate (BHB), free fatty acids (FFS) and triglycerides were measured in blood taken before (wk 7), during (wk 8-16 of age), and post-weaning in wk 20 by biochemistry. Data were analysed by the Mixed Model of SAS with feeding group, time, sex as fixed effects. Data on feed intake and growth performance are reported in a companion abstract [2]. Plasma concentrations of total protein and albumin increased ($P < 0.05$) during the weaning process and plasma albumin in FAST was higher ($P < 0.05$) than in SLOW (wk 11 and 13) and BWG (wk 11). Plasma urea concentration increased ($P < 0.05$) with time and was higher ($P < 0.05$) in FAST than in SLOW and BWG in wk 11. Plasma lactate concentration was lower ($P < 0.05$) in FAST than in CON in wk 10. Plasma glucose concentration declined ($P < 0.05$) during the weaning process and was lower ($P < 0.05$) in FAST than in SLOW (wk11), in CON (wk 9-12 and 14) and in BWG (wk 9-12). Plasma BHB concentrations increased ($P < 0.05$) during weaning in all groups, was highest ($P < 0.05$) in FAST from wk 10 to wk 14 and was lowest ($P < 0.05$) in CON from wk 14 to wk 16. Plasma FFS concentration decreased ($P < 0.05$) by time. Plasma FFS in FAST was highest ($P < 0.05$) in wk 10, was lowest ($P < 0.05$) in wk 13 and was lower ($P < 0.05$) than in SLOW (wk 12) and in CON (wk 14). Plasma triglyceride concentration decreased ($P < 0.05$) with time and was higher ($P < 0.05$) in SLOW than in FAST and BWG in wk 11. Changes in BHB and glucose mirrored the weaning process and BHB indicated a greater rumen papilla activity especially in FAST at the beginning of weaning. Higher plasma FFS and urea concentrations in FAST may indicate transient mobilization of fat and protein tissue to compensate for lower nutrient availability due to lower MR intake during weaning [2]. Effect of weaning duration (3 vs. 6 weeks) on plasma acylcarnitine and free fatty acid profiles in ad libitum–fed dairy calves

M. Hosseini Ghaffari[1], A. Stoschus[1], L. E. Diesing[1], S. Schuchardt[2], H. M. Hammon[1]
[1] Research Institute for Farm Animal Biology, (FBN), 18196 Dummerstorf, Germany, [2] Fraunhofer Institute for Toxicology and Experimental Medicine, ,, 30625 Hannover, Germany

Early-life milk allowance is a key regulator of growth performance and metabolic programming in dairy calves; however, the mitochondrial adaptations accompanying weaning under elevated milk intake remain insufficiently defined. This study investigated the effect of weaning duration (3 vs. 6 weeks) on plasma acylcarnitine and free fatty acid profiles in Holstein calves fed milk replacer (MR) ad libitum. We hypothesized that a gradual 6-week step-down weaning would promote a more stable oxidative transition than a shorter 3-week weaning. Twenty calves were enrolled at approximately 1 week of age, group-housed, and offered MR ad libitum (peak allowance up to 25 L/day) until week 7. At week 8, MR intake was standardized to 12 L/day, after which calves were stratified by body weight and sex and randomly assigned (n = 10/group) to either a 3-week or 6-week linear step-down weaning protocol. Solid feed management was identical across treatments. Plasma samples collected at weeks 10, 13, and 16 were stored at −80°C and analyzed using the Biocrates MxP 500 kit. Data were evaluated using linear mixed models with repeated measures, including fixed effects of weaning strategy, time, sex, and their interactions, and calf as a random effect. Complementary multivariate analyses were conducted via MetaboAnalyst6.0. As designed, calves subjected to the 6-week protocol exhibited a more gradual decline in MR intake and maintained higher milk consumption during early transition. Despite these differences in nutrient supply dynamics, weaning duration did not exert a significant main effect on average daily gain or body weight, although both variables changed over time and differed between sexes. Multivariate analysis revealed marked temporal remodeling of the plasma acylcarnitine profile across the weaning period, with sampling week accounting for the largest proportion of variance. Free carnitine concentrations were influenced by both age and treatment and were higher in calves undergoing gradual weaning during early transition. Short-chain acylcarnitines (C2, C3, C3-DC/C4-OH, C4) were predominantly driven by developmental stage, consistent with maturation of intermediary and mitochondrial metabolism. Treatment-related effects were selective: C5, C5-DC, and C5:1 were elevated in 6-week calves, whereas C6 and C6:1 were greater in 3-week calves; C8 increased transiently following rapid milk reduction, suggesting acute alterations in lipid flux. Most medium- and long-chain acylcarnitines were age-dependent; however, C10:2, C14:2, C16, and C16:1 displayed treatment-specific trajectories favoring gradual weaning during transition. Plasma fatty acids exhibited parallel temporal restructuring, including reductions in several C18–C20 and polyunsaturated species by week 16. Collectively, ontogeny emerged as the dominant determinant of metabolic remodeling during weaning under ad libitum MR feeding, whereas a 6-week step-down selectively modulated mitochondrial lipid-handling pathways and may facilitate a more stable oxidative shift toward a rumen-driven metabolic phenotype.

Prevalence of ESBL/AmpC-E. coli before and after the implementation of specific intervention measures in two dairy farms

J. F. Kleist[1], C. Silhavy[1], T. Homeier-Bachmann[2], L. Bachmann[1]
[1] University of Applied Sciences, Brodaer Str. 2, 17033 Neubrandenburg, Germany, [2] Friedrich-Loeffler-Institut, Südufer 10, 17493 Greifswald, Germany

Dairy farms have been identified as a significant reservoir for ESBL/AmpC-E. coli (Gonggrijp et al., 2016). On-farm practices, including antibiotic treatments and hygiene measures in both cows and calves, have been identified as important risk factors in the development and spread of ESBL/AmpC-E. coli (Weber et al., 2021). Hypothesis: The implementation of farm-specific intervention measures on dairy farms, emphasizing disease treatment and general hygiene practices, can reduce the prevalence of ESBL/AmpC-E. coli at farm level. Experimental methods: On two dairy farms (farm 1: 200 and farm 2: 550 lactating cows), fecal samples were collected from animals of all ages and additionally, environmental samples were collected from bedding and feeding equipment. These samples were used to determine the initial prevalence of ESBL/AmpC-E. coli at farm level using bacteriological methods. A questionnaire was used to identify on-farm practices associated with the occurrence of ESBL/AmpC-E. coli. Based on the results of the bacteriological examination and the identified potential risk factors, farm-specific intervention measures were introduced and implemented. The measures included treatment plans for relevant diseases in calves and cows, as well as cleaning and disinfection plans for various housing sections and equipment. Additional sampling was conducted after a one-year period to ascertain whether any alterations in the prevalence of ESBL/AmpC-E. coli had occurred. Statistical analyses: A chi-square test was performed to determine if the implemented measures had led to a statistically significant reduction in the prevalence of ESBL/AmpC-E. coli. Results, discussion and conclusion: The initial conditions were disparate on the two farms, with prevalence rates of ESBL/AmpC-E. coli at farm level being 9% on farm 1 and 41.1% on farm 2. On both farms, the prevalence of ESBL/AmpC-E. coli was age-dependent, with the highest prevalence observed among calves and young heifers, and their immediate environment. Minimal to no occurrence was observed among adult cows. Additional sampling of the farms one year after the implementation of farm-specific intervention measures, revealed a significant decline in the prevalence of ESBL/AmpC-E. coli with a decrease to 1.3% on farm 1 ($P < 0.001$). The reduction to 36.1% on farm 2 was not statistically significant ($P = 0.096$). A potential explanation for the observed differences in the results at farm level could be the higher initial prevalence of ESBL/AmpC-E. coli on farm 2. Given the high contamination levels, it can be posited that a one-year period is insufficient to achieve significant changes in the prevalence at farm level, as the reservoir of antimicrobial resistant bacteria is larger. Furthermore, on farm 2, the implementation of certain measures was inconsistent with the prescribed protocol, constituting an additional explanatory approach for the differing results. The present study showed that the prevalence of ESBL/AmpC-E. coli could be significantly reduced by specific measures that target relevant risk factors regarding ESBL/AmpC-E. coli on farm 1, which had low initial prevalence rates. For farm 2, with higher initial prevalence rates, a reduction without reaching statistical significance could be achieved within one year. A significant decrease of ESBL/AmpC-E. coli prevalence in high contaminated farms probably takes longer. Subsequent studies with a larger sample of farms are required to ascertain the reproducibility of the results and to generate statistically reliable findings.

Lung scanning at arrival of calves in veal calf herds

H. L. Martin[1], A. M. Kjeldsen[1]
[1] SEGES Innovation, Agro Food Park 15, DK-8200 Aarhus N, Denmark

BackgroundRespiratory disease is the most significant health challenge in Danish veal calf herds. The aim of this study was to describe the prevalence of ultrasound-detectable lung lesions in Danish veal calves on the day of arrival. Materials and methodsA total of 678 clinically healthy calves from 132 Danish dairy herds were examined by ultrasound on the day of arrival at 7 different veal calf herds. Scanning was performed using a linear probe (Easy Scan) with a frequency of 7.5-MHz. The scans were conducted according to a standardized protocol (qTUS). Calves were scanned on both right and left sides of the thorax from the 6th intercostal space and cranially. Lesions were classified according to qTUS system (score 0 – no lesions; score 1 – consolidations <1 cm ; score 2 – consolidations 1–3 cm; score 3 – consolidations ≥3 cm). Calves with lung scores of 2 or 3 were considered to require treatment and are referred to here as having subclinical pneumonia. ResultsAll 678 calves included in the study appeared clinically healthy at arrival. However, lung ultrasound revealed that a considerable proportion of calves already had detectable lung lesions. Overall, 61% of calves had no detectable lesions, while 39% showed varying degrees of lung changes. In total, 19% of calves had lesions classified as subclinical pneumonia (qTUS score 2–3), despite the absence of clinical signs. The prevalence of subclinical pneumonia varied between visits, ranging from 12% to 30%. Only minor differences were observed in the prevalence of subclinical lung lesions between heifer and bull calves and between different breeds. Likewise, previous treatment for diarrhea or pneumonia in the source herd showed only small differences in the prevalence of subclinical pneumonia. Follow-up data indicated that calves with more severe lung lesions at arrival tended to have higher subsequent mortality and required more treatments for pneumonia during the first 90 days after arrival. Conclusion:The results show that a considerable proportion of Danish veal calves already have subclinical pneumoniaat the time of arrival. These changes would not be found by routine clinical examination. The prevalence of subclinical pneumonia is comparable to that reported in several international studies. Ultrasound examination upon arrival to veal calf herds may contribute to reduced respiratory problems. Early detection makes it possible to initiate targeted treatment of calves with subclinical infections. Early treatment is expected to contribute to more effective therapy, improved recovery, lower mortality, reduced transmission, fewer cases of recurrent pneumonia, and thus overall fewer treatments and reduced antibiotic use. Lung scanning at arrival also makes it possible to identify source herds with particular challenges and thereby opens opportunities for targeted preventive interventions among selected dairy producers. Any future restrictions on antibiotic use may increase the need for lung ultrasound as an early diagnostic tool at the time of calf arrival in veal calf herds.

Normal or low iron level in milk replacers for 1 to 2 months old dairy-beef calves

C. B. S. Geven[1], N. B. Kristensen[2], H. L. Martin[1], M. L. Petersen[1], M. Vestergaard[1,2]
[1] SEGES Innovation, Agro Food Park, 8200 Aarhus N, Denmark, [2] Aarhus University, Foulum, Blichers Allé 20, 8830 Tjele, Denmark

Most calf milk replacers (MR) have an iron (Fe) content of 75 to 90 mg/kg. This is much higher levels than found in whole milk. A calf fed moderate to high levels of whole milk will experience a nadir in blood Fe levels around 5-6 weeks of age. When the calf starts to eat concentrate and forage, the Fe content in the feed ration, as well as in the blood, increases. Only a few studies have shown a positive effect of supplying extra Fe to milk-fed calves. Most dairy-beef calves arrive at the fattening farm at 3 to 5 weeks of age. Our research objective was to assess whether a milk replacer with a lower Fe content would be adequate for maintaining recommended hematocrit and hemoglobin levels as well as growth (average daily gain) in calves. Therefore, a standard (S: 78 mg Fe/kg) and Low (L: 30 mg Fe/kg) MR was fed to calves and they also had access to pelleted concentrate and barley straw. Calves arrived in a commercial fattening farm in two batches 2 weeks apart. Within each batch, treatments were assigned randomly to 2 x 2 pens. Thus, a total of 173 calves were housed in 2 x 4 pens each housing 22-25 calves. Calves were 11-54 days of age at start. Pens were straw-bedded. Milk-feeding through automatic feeders continued for 50 days after arrival. Blood samples were taken from 6 calves per pen (n=48) at 5-6 weeks of age to access hematocrit (packed cell volume) and whole blood hemoglobin concentrations. Average daily gain was based on weights at arrival and weight shortly after weaning. Individual veterinary treatments during the study period were recorded. Data was analyzed using linear and mixed models in R with pen as the statistical unit. Average daily gain (800 vs. 805 g/d), blood hematocrit (39.7 vs. 38.0), plasma hemoglobin (8.2 vs. 8.1 mM), and number of treatments against pneumonia (0.95 vs. 1.05) were not different between S and L-calves. All hematocrit-values were in the normal range with only 2 cases between 25 and 30 and 3 high cases between 45 and 52, all not related to the MR-type. All measured hemoglobin levels were above EU required threshold level of 5.3 mM. In conclusion, a low-Fe MR (30 mg Fe/kg) is adequate for maintaining hematocrit and whole blood hemoglobin concentrations as well as health and growth of 1-2 months old preweaned calves offered concentrate and forage.

Alternative forage sources to wheat straw in crossbred dairy beef calves fed high-concentrate diets

L. Llonch[1], S. Marti[1], A. Solé[1], N. Naranjo[1], Á. Serrano[1], J. Riera[2], C. Medinyà[3], J. Cucurull[4], M. Devant[1]
[1] IRTA, Ruminant Production, Torre Marimon, Caldes de Montbui, 08140 Barcelona, Spain, [2] NANTA S.A., Tres Cantos, 28760 Madrid, Spain, [3] SINUAL, Sallent, 08650 Barcelona, Spain, [4] Grup BonÀrea, Guissona, 25210 Lleida, Spain

The increasing scarcity and interannual variability of straw availability driven by climate change is prompting the search for alternative forage sources in fattening dairy beef bulls. We hypothesized that several non-conventional forages could replace wheat straw without compromising feed intake. The aim of this preliminary study was to evaluate if in crossbred dairy beef calves three potential alternative forages would have detrimental effects on intake. Twenty recently weaned crossbred bull calves (99 ± 1.2 kg of BW; and 92 ± 1.4 days of age) were individually housed in hutches with sawdust bedding on a concrete floor at a commercial farm in Montgai (Lleida, Spain) during October 2025. Calves were assigned to one of four treatments that differed in the type of forage offered ad libitum, provided in separate feeders from the concentrate: 1) WS (n=5), wheat straw; 2) PN (n=5), panicum; 3) FE (n=5), fescue; and 4) FE+ (n=5), high-quality fescue with greater crude protein content. The trial lasted 14 days. Body weight was recorded at the beginning and end of the study. Individual daily intake of concentrate and forage was measured, and health status, including bloat and fecal scores, was monitored. Forages and concentrate were analyzed for crude protein (CP), ether extract (EE), ash, starch, neutral detergent fiber (NDF) and acid detergent fiber (ADF). Data were analyzed using a mixed-effects model including treatment, day, and their interaction as fixed effects, with initial BW as a covariate, and with day as a repeated measure. Overall and nutrient-specific forage intakes were square-transformed to achieve normality. Concentrate intake did not differ among treatments (P = 0.76; 3.30, 3.09, 3.34, and 3.29 ± 0.253 kg DM/day for WS, PN, FE, and FE+, respectively). Although overall forage intake was also unaffected by treatment (P = 0.22; 0.272, 0.331, 0.409, and 0.316 ± 0.055 kg DM/day for WS, PN, FE, and FE+, respectively), a significant treatment by day interaction (P < 0.01) indicated that calves consumed more FE across on most days, with PN and FE+ showing intermediate values and WS the lowest. Nutrient intake from forage also showed significant treatment by day interactions, and some showed clear treatment effect: forage CP intake was higher in PN and FE+ than in WS and FE (P < 0.01; 16.8, 39.2, 17.1, and 30.5 ± 14.65 g CP/day for WS, PN, FE, and FE+, respectively); forage EE intake was higher in PN and FE+ than in WS (P = 0.01; 4.02, 7.87, 4.40, and 5.97 ± 6.897 g EE/day for WS, PN, FE, and FE+, respectively); forage starch intake was greatest in PN (P < 0.01; 0.30, 1.50, 0.46, and 0.36 ± 2.417 g starch/day for WS, PN, FE, and FE+, respectively); and forage ADF intake was greatest in FE (P = 0.01; 129, 130, 238, and 116 ± 37.7 g ADF/day for WS, PN, FE, and FE+, respectively). In conclusion, the forage alternatives tested in this preliminary study appear to be promising substitutes for wheat straw, with some, like fescue, showing the potential to even increase forage consumption. As the nutrient intake of the alternative forage sources differed from wheat straw, overall nutrient intake was affected. Given the inherent variability in forage composition, longer-term studies are needed to further assess the potential of these forages as viable alternatives to conventional wheat straw in dairy beef calves fed high-concentrate diets.

Performance and Meat Quality of German Holstein Steers in a Silvopastoral System

T. Krebs[1], A. Boldt[2], R. Wulf[3], S. Maak[4], K. Barth[1]
[1] Johann Heinrich von Thuenen Institute, Trenthorst 32, 23847 Westerau, Germany, [2] Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [3] Neubrandenburg University of Applied Sciences, Brodaer Str. 2, 17033 Neubrandenburg, Germany, [4] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany

Cattle production is a cornerstone of German agriculture, with dairy farming contributing substantially to animal product value. Beyond milk and replacement heifers, dairy systems inevitably produce male calves, whose future remains a major sustainability challenge. This dilemma is particularly evident in organic farming, where only about 10% of male calves remain on their farms of origin, while most are conventionally fattened or exported, practices increasingly criticized for animal welfare, regionality and environmental responsibility. Yet beef from dairy breeds can achieve high quality and may improve climate efficiency. Despite this potential, data on organic, pasture-based fattening of Holstein males of the current genetic are scarce. We therefore investigate silvopastoral grass-based fattening of German Holstein steers under organic conditions as a sustainable and economically viable alternative. The study was conducted at the Thuenen Institute of Organic Farming and included 50 German Holstein steers allocated equally to two experimental groups: pasture with access to a fodder hedge (n=25) or without hedge access (n=25). Animals were raised in two consecutive fattening runs (2023/2024, n =26; 2024/2025, n=24), with balanced group distribution per year. Steers underwent two grazing seasons separated by winter housing. During the grazing periods, animals received no supplementary feed. During winter housing, steers were offered a total mixed ration (TMR) composed of grass silage, maize silage and 1kg concentrate. Animals were weighed weekly from birth until slaughter at 20 ± 1 months. Carcass and meat quality traits were assessed post mortem in the M. longissimus dorsi, including pH (45min, 24h), colour (L*, a*, b*), intramuscular fat (IMF), drip loss, cooking loss and shear force. Statistical analyses were performed in R. Growth was analysed using generalized additive mixed models (REML) including treatment and housing period as fixed effects, age as group-specific smooth term, and animal ID as random effect. Differences in growth curves were evaluated via smooth contrasts. Period-specific daily gains were analysed using linear mixed models. Meat quality traits were analysed using linear models including treatment, year, slaughter time, age and weight as fixed effects. Model assumptions were verified by residual diagnostics. Hedge access had no significant effect on growth or meat quality traits ($p>0.05$). Steers achieved high daily gains with hedge (897 ± 77g) and without (901 ± 67g). Housing significantly affected performance ($p<0.05$), with higher gains during winter housing (1154 ± 171g) than during grazing (861 ± 260g), although pasture gains remained comparable to bulls in similar systems. Slaughter weight and age were within expected ranges. Meat quality was consistently high, with an intramuscular fat content of 4.9 ± 1.6% and low shear force values (53.0 ± 15.6N), indicating very good tenderness. The elevated IMF and favorable tenderness reflect typical steer characteristics and support superior eating quality. Overall, the results demonstrate that pasture-based fattening of Holstein steers can achieve high performance and very good meat quality with limited concentrate use. This system represents a sustainable and welfare-oriented alternative for integrating male dairy calves into regional beef production.

Evaluating short and long colostrum replacer protocols to support recovery in dairy beef calves after transportation

C. J. García Vázquez[1], M. Verdu[2], J. Cucurull[2], X. Soldevila[2], M. Devant[1], S. Marti[1]
[1] IRTA, Ruminant Production, Torre Marimont, 08140 Caldes de Montbui, Spain, [2] BonÁrea Agrupa, carrer de ponent, 25210 Guissona, Spain

Dairy beef calves are transported from dairy farms to rearing units, a process that induces stress, triggers nutrient mobilization, and compromises gut health due to fasting. Upon arrival, calves typically show reduced feed intake and growth, along with a higher risk of respiratory disease. Implementing nutritional strategies immediately after arrival may help mitigate these negative effects by promoting early recovery of gut function and feed consumption. Supplementing colostrum—rich in bioactive compounds involved in gut cell development and inflammation—has emerged as a promising approach to support calves during this transition. Commercially available colostrum replacers vary in manufacturing processes and, consequently, in quality. Moreover, the optimal supplementation protocols, including dose and duration, remain to be defined for each product. This is a preliminary study that evaluates two post-arrival colostrum replacer (Calvicol Green, Hokovit, Switzerland) supplementation protocols on performance and feed periods adapt sported dairy beef calves. Ninety-six Holstein unweaned calves were transported from France to Spain in two batches of 48 calves. Upon arrival calves were allocated in individual hutches and distributed by body weight (BW) and lung ultrasonography score to one of the three treatments based on colostrum replacer supplementation: control (CTR) , calves were fed 2.5 L of milk replacer at 125 g/L twice daily; short CR supplementation (SCR), calves were fed 2.5 L of milk replacer at 125 g/L twice daily and were supplemented with 20 g of CR on d0 feeding and 10 g on d1 at the morning feeding; or long CR supplementation (LCR) calves were fed 2.5 L of milk replacer at 125 g/L twice daily and were supplemented with 20 g of CR on d0 feeding and 10 g on d1–3 only in the morning feedings. The SCR supplementation protocol was based on the manufacturer recommendations. Concentrate feed was offered ad libitum. On day 43 calves were weaned and moved to a barn to be allocated in pairs based on their treatment. The study lasted 64 days. Body weight was recorded weekly and feed intake daily. Performance data was analysed in two periods based on housing (d0–43 and d44–64) using mixed-effects models with treatment, period, and their interaction as fixed effects, pen and batch as random effect, and initial BW as covariate. An interaction between treatment and time ($P < 0.05$) was observed in BW, average daily gain (ADG), and milk replacer intake in the first period (d0 to 43). The SCR calves had lower BW and ADG on d 7 after arrival, and lower milk replacer intake on d 7 and 14 after arrival compared with CTR and LCR calves. In the second period where calves were allocated in pairs, only a tendency ($P=0.08$) in ADG was observed among treatments being ADG lower in LCR calves (1.09 ± 0.057 g/d) compared with CTR and SCR calves (1.21 ± 0.057 g/d and 1.26 ± 0.057 g/d, respectively). In this study, the tested supplementation protocol—considering the type of colostrum replacer, the administered amount, and the duration—did not enhance calf performance or feed intake; in some cases, the effects were even unfavorable. Although colostrum supplementation upon arrival remains a promising approach, further research is needed. The quality of the supplement, as well as the dosage and length of supplementation, are likely key factors influencing the ability to support recovery of growth and health after long-distance transportation

Evaluation of the effect of social housing practices for replacement and fattening calves from birth to transport and later stages of life

J. J. Hayer[1], A. Peine[1], C. Göckeritz[2], K. Bauch[2], P. Berghuis[3], S. Schäfer[4], P. Schneider[4], D. Frieten[5], I. Steinhöffel[2]
[1] Educational and Research Centre for Animal Husbandry, Hofgut Neumühle,, Neumühle 1, 67728 Münchweiler, Germany, [2] Saxon State Office for Environment, Agriculture and Geology (LfULG), Am Park 3, 04886 Köllitsch, Germany, [3] Berghuis GmbH, Prozessionsweg 48, 49479 Ibbenbüren, Germany, [4] Schneider Elektronik GmbH & Co.KG, Dresdener Str. 29, 01909 Großharthau, Germany, [5] University of Applied Sciences, Department of Agriculture, Berlinstraße 109, 55411 Bingen, Germany

Recent studies have shown that early socialization in calves influences behavior, growth, and feed intake both during the rearing period and later in life. While individual housing throughout the milk-feeding period is common worldwide, calves in Europe are usually housed individually only during the first weeks of life before group housing. However, little research has investigated whether social housing in the first weeks provides additional benefits for dairy calves. Moreover, evidence regarding the long-term effects of early social housing remains limited, particularly for dairy calves sold for fattening. This study compares early housing strategies during the first 28 days of life regarding calf health, development, and behavior and evaluates effects in later production stages. The study is being conducted on three German dairy farms with Holstein Friesian and Holstein Friesian × Simmental crossbred calves. Data collection began in June 2024 and will continue until August 2027. Calves were assigned to five housing groups: individual (S28), pair from day 1 (S0P), 7 days individual then pair (S7P), group from day 1 (S0G), and 7 days individual then group (S7G). Calves receive ad libitum transition milk (d 0–10) and milk replacer (d 11–28; 135 g/L). Water, hay, and calf dry TMR are offered ad libitum. During the first 28 days, calves underwent daily health assessments (9 parameters); milk intake was recorded daily, and body weight, umbilical scores, and behavior were monitored weekly or continuously (video). After the 28-day rearing period, female calves are moved to group housing and managed according to individual farm management programs. Male calves are transported to the same calf collection center and then transferred to different fattening facilities. During transport, calves are fitted with heart rate monitors. To assess potential long-term effects of the early housing treatments, weight gain in replacement heifers is monitored, and weight gain in male calves is evaluated throughout the fattening period until slaughter. So far, 147 female Holstein calves, 61 male Holstein calves, and 11 male Holstein × Simmental crossbreds have completed the initial 28-day focus period (S28 = 64; S0P = 56; S7P = 50; S0G = 11; S7G = 30).Based on preliminary evaluations of daily milk intake from one farm, individually housed calves consumed, on average, numerically but not statistically significantly more milk (S28 = 9,172 mL) compared to pair-housed calves (S0P = 8,596 mL; S7P = 8,820 mL).Social housing had a significant impact on average daily gain (ADG) during the first 28 days of rearing (S28 = 981.9 g; S0P = 884.8 g; S7P = 818.2 g; S0G = 674.0 g; S7G = 764.4 g). ADG in S28 was significantly higher than in S7P, S0G, and S7G.Male Holstein calves were slaughtered at an average age of 237 days, with an average carcass weight of 175.2 kg (n = 23). The average daily gain from 4 weeks of age until slaughter was 529.0 g.Overall, preliminary analyses indicate differences among housing treatments; however, a comprehensive assessment must also incorporate health and behavioral data, as well as longer-term effects on subsequent behavior and productivity, which are integral components of this study.

Comparative effects of two sensory feed additives on recovery and adaptation of commercially transported unweaned dairy beef calves from arrival to post-weaning

J. J. Narváez[1], N. Llanes[1], M. Blanch[2]
[1] Cooperativa d'Ivars, C/ Lleida, 2-8, 25260 Ivars d'Urgell, Spain, [2] Lucta, S.A., Innovation Division, Av de Can Domènech s/n, 08193 Bellaterra, Spain

Stress and feed deprivation during marketing and transport can impair the early adaptation of unweaned dairy beef calves upon arrival at the rearing farm. The use of sensory feed additives (SA) to stimulate feed intake may support recovery and enhance subsequent performance. Sensory additives may provide olfactory (aroma) and/or gustatory (taste-enhancing) stimulation. This study aimed to compare two SA: one based on a milky aroma (AROMA) and another combining a milky aroma with a sweetener (AROMA+SWEET). A total of 105 Montbéliarde calves (64.6 ± 0.99 kg body weight; 4 weeks of age), commercially transported for 8 h, were monitored for 10 weeks after arrival at a rearing farm. Calves were fed 2 L of milk replacer (MR; 12% solids) twice daily from d1 to d12, 1.5 L twice daily from d13 to d24, and 1.5 L once daily from d25 to d32. Calves were fully weaned on d32 and had ad libitum access to concentrate throughout the study. Animals were allocated to 10 pens (10–11 calves/pen) and assigned to one of two treatments (5 pens/treatment) according to the SA included in the concentrate: AROMA or AROMA+SWEET. Individual body weight (BW) and pen-level concentrate intake were recorded. Data were analyzed using a mixed-effects model. Average daily gain was greater in AROMA+SWEET calves during the pre-weaning period (P = 0.04) and tended to be greater over the entire experimental period (P = 0.10) compared with AROMA calves (+90 g/d and +68 g/d, respectively). Calves receiving AROMA+SWEET had greater BW at weaning (P = 0.04) and tended to maintain higher BW at the end of the trial (P = 0.11) compared with AROMA calves (d32: 91.4 vs. 88.5 ± 1.02 kg; d69: 130.6 vs. 126.0 ± 2.02 kg, respectively). In addition, average concentrate intake over the entire period was greater in AROMA+SWEET than in AROMA calves (2.12 vs. 1.96 ± 0.09 kg/d). In conclusion, supplementation with a sensory additive combining an aroma with a sweetener increased concentrate intake and improved growth performance in dairy beef calves following transport compared with an aroma alone. This strategy may represent a practical nutritional approach to support post-transport recovery and enhance subsequent performance. Keywords: dairy beef calves, sensory additives, post-transport adaptation

Spanish consumer preferences for meat credence signals in beef and lamb: evidence from a mixed logit model

M. A. Cantarero-Aparicio[1], E. Angón[1], J. Claros-Zafra[1], M. Luque-Cuesta[2], J. M. Perea[1]
[1] Universidad de Córdoba, Producción Animal, Producción Animal - Campus Agroalimentario de Rabanales, 14071 Córdoba, Spain, [2] Real Federación Española de Asociaciones de Ganado Selecto (RFEAGAS), C/ Castelló, 45, 28001 Madrid, Spain

Consumers are increasingly concerned about sustainability and production practices in livestock systems, which has led to the development of several quality and environmental labels for meat products. Understanding how consumers value these attributes is essential for improving market differentiation strategies in the livestock sector. This study aimed to evaluate consumer preferences for sustainability-related labels in beef and lamb using a discrete choice experiment. A survey-based choice experiment was conducted in which respondents evaluated meat products characterized by different attributes: price, "100% Native Breed" label, environmental traffic-light label, Protected Geographical Indication (PGI) and Animal welfare label. Consumer choices were analysed using mixed logit models to account for preference heterogeneity. Three models were estimated: a model including both meat products and species-specific models for beef and lamb. Results showed that all attributes significantly influenced consumer choice ($P < 0.01$). Price had a negative effect, as expected, indicating sensitivity to price increases. Sustainability and quality-related attributes had strong positive effects. The environmental improvement from yellow to green showed the largest positive effect in the pooled and beef models, whereas the "100% Native Breed" label showed the strongest effect in lamb. Animal welfare and PGI labels also significantly increased the probability of product choice. Overall, results suggest that consumers strongly value sustainability-related attributes, particularly environmental performance and local breed identification. These findings highlight the market potential of environmental, origin and animal welfare labels to enhance differentiation strategies for beef and lamb products.

Better-Calf: Dairy calf systems for resilience, welfare and sustainability in rural territories

The agricultural sector in north-west Europe is facing several challenges including: (1) economic (e.g. low farm incomes), (2) environmental (e.g. climate change, ammonia, biodiversity decline), and (3) social (e.g. competition for land between producing 'feed' for animal production and 'food' for human consumption, animal welfare, high quality affordable food). These challenges have contributed to a decrease in the number of family farms (e.g. 51% of retiring farmers have no successor in France, 44% in Wallonia), with small farms particularly vulnerable (e.g. 'small' farms in Ireland are reducing at the rate of 1.5% per year). This has implications for rural resilience and the preservation of cultural landscape and biodiversity. Grass-based beef cattle production systems can help to address these challenges. The low cost of grazed pasture when compared to conserved forage such as corn silage and concentrate feeds create opportunities for profitable production systems. Such grass-based systems also imply low competition between human food and animal feed (since livestock are otherwise fed grains which could instead be fed directly to humans), may increase soil carbon storage and improve water quality while also producing local and high-quality food. There is a particular opportunity for livestock farmers to use dairy calves, specifically those not required as replacements in the dairy herd, and to add value to these calves by growing them to mature weights as beef cattle. Presently these calves are often reared in veal production systems. Given ethical concerns with veal systems there is interest in increasing the proportion of dairy calves that are produced in grass-based beef production systems. There are a very wide range of dairy-calf systems that are operated at farm level. Farmers and other stakeholders are often unclear on which system is preferred. The "Better-Calf" project, funded by Interreg North-West Europe, aims to support rural areas and family farms by providing them with tools to optimise grass-fed dairy calf rearing systems. The project will test and promote the implementation of resilient dairy calf systems . Through the support of local and/or national public bodies we aim to create territorial plans for the development of a dairy calf supply chain with optimised management practices. A survey of north-west European citizens and consumers will set out the expectations for the production of dairy-beef and the evaluation of their willingness to pay for those products. Dairy calf systems will be tested on experimental farms with a focus on maximising access to pasture thereby promoting animal welfare. A network of 40 commercial farms across Belgium, France, Germany, Ireland, Luxembourg and Switzerland will be created encompassing a large range of the soil and climatic conditions of north-west Europe. Finally, we will engage with the economic actors in the dairy and beef sectors and public bodies to develop action plans to implement the local production of dairy-beef that maximises returns to all actors and create a more viable sector.

Fresh vs. ensiled Rose (Rosa rugosa Thunb.) pomace: effects on rumen methane production and fatty acid biohydrogenation in vitro

S. Olorunlowu[1], P. Sidoruk[1], J. Sznajder[1], J. Szczesny[1], B. Ola[1], S. Ślusarczyk[2], A. Cieslak[1]

Rosa rugosa fruit pomace (RFP) is a polyphenol-rich agro-industrial by-product from juice production that could support circular feed systems while potentially modulating rumen fermentation, protozoal activity, methane formation, and biohydrogenation (BH) of unsaturated fatty acids. This study evaluated fresh (RFPF) and ensiled (RFPS) RFP in two in vitro 24-h batch-culture studies (3 independent runs per study) using 400 mg substrate incubated with 40 mL buffered rumen fluid. RFP was sourced from a local Polish processor; a portion was ensiled in 4-dm³ microsilos using a silage additive, and samples were analysed for seed proportion, chemical composition, and phytochemicals. Total polyphenols/tannins were extracted (70% hydrated acetone; ultrasound-assisted extraction), quantified by Folin–Ciocalteu, and profiled by LC–ESI-QTOF-MS. Study 1 compared grass silage (control) with pure RFPF and RFPS. Ensiling increased total polyphenols (465 to 509 mg GAE/100 g DM) and altered the tannin fraction (264 to 228 mg GAE/100 g DM). In pure form, both RFPF and RFPS decreased ammonia, acetate proportion, and methane production (mM/g DM), increased propionate, and reduced the acetate:propionate ratio versus grass silage. Study 2 incorporated RFPF or RFPS into dairy cow total mixed rations at 0, 20, 40, 80, and 100 g/kg DM. Across inclusion levels, ruminal pH was maintained, and IVDMD/IVOMD declined only slightly; the high seed fraction of the pomace (~63%) likely contributed to this modest digestibility response. RFP reduced H□ concentration and decreased total protozoa numbers, but methane yield did not consistently decline up to 100 g/kg DM, suggesting that the effective dose of bioactive compounds was insufficient to strongly affect methanogenesis under these short-term conditions. RFP also modified fatty acid BH in vitro. For fresh RFP, linoleic acid BH decreased (87.0% in control to 83.8–85.0%), and linolenic acid BH showed small reductions at selected inclusions (minimum 87.0% at 80 g/kg). For ensiled RFP, linoleic acid BH decreased at low inclusion (e.g., 82.0% at 20 g/kg vs 86.2% control), while linolenic acid BH varied across inclusions (84.7–90.6%). Overall, RFP (particularly when ensiled) shows promise as a local, low-waste feed ingredient for shifting fermentation toward propionate and reducing protozoa and BH, with only a modest methane-mitigating effect in 24-h batch culture. These results justify follow-up work in longer-term and more dynamic systems (e.g., RUSITEC/in situ) to better resolve dose–response relationships and impacts on methanogens and fermentation stability.

Effect of a combination of hazelnut and cocoa bean by-products on in vitro ruminal fermentation and biohydrogenation

R. Senatore[1,2], M. Coppa[2], C. Baila[1], G. Hervás[1], P. Cornale[2], P. Frutos[1], P. G. Toral[1]

Hazelnut skin (HZN) and cocoa bean shell (CBS) are agro-industrial by-products, rich in fatty acids (FA) (HZN) and bioactive compounds (phenols in HZN and CBS, and theobromine in CBS), that could be valorised as feed for ruminants, promoting circular economy. Several studies reported modulatory activity on ruminal fermentation and biohydrogenation of individual HZN or CBS in ruminant diets. However, little is known about their possible additive or synergistic effects. This in vitro study evaluated ruminal fermentation and biohydrogenation responses to the addition of a HZN and CBS blend in ruminants' diet. Batch cultures of rumen microorganisms were conducted using rumen fluid from three cannulated ewes. The basal diet was composed (% DM) of grass silage (43), hay (35), and cereal- and soybean-based concentrates (22). Three inclusion levels (0, 1.5, and 3.0% diet DM) of each by-product, alone or as their 50/50 mix, were incubated for 30 h and total gas (GP) and CH4 productions, volatile fatty acid (VFA) yield and proportions were measured. Data were analysed with R software using a linear mixed model with treatment as fixed effect and incubation run as random effect, followed by Tukey's post-hoc test. The GP decreased with the HZN-CBS blend at both the 1.5 and 3.0% inclusion levels (−7% and −8%, respectively). A similar trend was observed with HZN at 1.5% and CBS at 3.0% (–5% and −9%, respectively). Treatments induced minor changes in VFA: a reduction in butyrate proportion and yield (on average, –8%) and proportional increases in acetate and propionate proportions (only significant at the 3.0% of HZN-CBS mixture). The greater supply of cis-9 18:1 with HZN resulted in higher levels of this fatty acid (range: +51 to +70%) and its isomerization products in HZN-containing treatments. Major biohydrogenation pathways (trans-11 and trans-10) were not affected. Inclusion of HZN in the diet increased the content of 9+10-oxo-18:0 (range: +152 to +229%), which derive from an alternative metabolic pathway of cis-9 18:1 metabolism, suggesting variations in microbial function or composition, in agreement with the parallel reductions in major odd- and branched-chain fatty acids. The CBS did not influence biohydrogenation, and no synergistic or antagonistic interaction with HZN emerged. The studied by-products appear as sustainable feed ingredients, with HZN showing additional potential to modify biohydrogenation. Acknowledgement: PIE202540E090 (CSIC, Spain). Horizon Europe AgroServ project n.101058020 (UNITO, Italy).

Effect of carrot inclusion level on the in vitro fermentation kinetics of dairy sheep diets

C. Saro[1,2], A. Díaz[1,2], I. Mateos[1,2], N. Merino[1,2], S. López[1,2], M. J. Ranilla[1,2]
[1] Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, [2] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, 24346 Grulleros, Spain

Spain ranks among the world's leading carrot producers; however, a significant portion of the harvest is discarded as surplus or cull carrots due to strict commercial standards. Within the framework of the circular economy, upcycling these discarded products as livestock feed offers a sustainable strategy to reduce environmental impact and feed costs. Given their high content of fermentable carbohydrates, the aim of this study was to evaluate the in vitro ruminal fermentation of dairy sheep diets with increasing amounts of carrots. Four isoenergetic and isoproteic diets (40:60 forage:concentrate) were formulated: a control diet (CON) and diets with 8, 16 and 24 % DM of carrots (CAR8, CAR16 and CAR24) replacing part of the concentrate of the CON diet. Three hundred mg of substrate (n=4) were incubated in batch cultures of ruminal microorganisms at 39 ºC, and gas production was measured at 3, 6, 9, 12, 17, 22, 26, 31, 36, 48, 72, 96, 120 and 144 hours. Endogenous gas production was corrected by subtracting the gas volume produced by the corresponding blanks from the total gas produced in the vials. Data were fitted to a nonlinear model to estimate potential gas production (A), fractional rate (c) and lag time. Average gas production rate (AGPR) and effective degradability of DM (DMED) were also calculated. Gas production values were fitted to the model: $Gas = A(1-e^{-c(t - Lag)})$, using the NLIN procedure of Statistical Analysis System (SAS). The asymptotic gas production was not affected by the replacement of concentrate with carrots (mean 72.6 mL/g DM; $P > 0.05$). However, increasing the carrot content in the diet led to a marked linear reduction in lag time (L; $P < 0.0001$), which decreased from 4.63 h in the CON diet to 2.15 h in CAR24. The fractional rate of gas production showed a quadratic response ($P < 0.001$), reaching its maximum value with the CAR16 diet (0.062 %/h). The average gas production rate increased both linearly and quadratically ($P < 0.01$), while the effective degradability of dry matter (DMED) showed a linear increase ($P < 0.0001$) as the level of carrots increased. Specifically, DMED values improved linearly from 32.9 % (CON) to 36.7 % (CAR24), indicating that the inclusion of carrots enhanced the rate and extent of the initial ruminal fermentation. The results indicate that the inclusion of carrots significantly enhances fermentation efficiency by reducing the lag time and increasing both the average gas production rate and the effective degradability of dry matter. Under the conditions of this study, a 16% inclusion level (CAR16) appeared to be the most efficient in terms of the fractional rate of gas production, providing the best balance between rapid energy release and microbial processing speed, suggesting that carrots are a high-quality alternative energy source for sheep, capable of accelerating the initial fermentative processes. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Rumen degradability, fermentation dynamics, and methane production of potato co-products using in vitro batch culture and rumen simulation technique

Potato processing generates large volumes of co-products with potential as alternative energy sources in ruminant diets, yet their comparative nutritional value and longer-term fermentation effects remain insufficiently characterized. This study evaluated ruminal fermentation characteristics, nutrient degradability, gas kinetics, and methane (CH4) production when five potato co-products—potato cream (PC), cooked potato chips (CPC), raw potato chips (RPC), potato slice (PS), and potato peel (PP)—replaced wheat grain in a control diet (CTL) formulated with a forage-to-concentrate ratio of 55:45 (DM basis). Three runs of a complementary in vitro batch culture system (72 h; n = 4 per treatment) screened all potato co-products, followed by a semi-continuous Rusitec trial (14 days; n = 4 per treatment) to evaluate the most promising co-products (PC and PS), using rumen fluid from donor cows fed a basal diet at maintenance energy level, with both experiments performed under completely randomized designs. Chemical composition differed markedly among co-products: fibre-rich PS and PP contained approximately 2.5-fold higher neutral detergent fibre than wheat grain, whereas thermally processed PC and CPC exhibited comparable or higher starch concentrations. In batch culture, PC and CPC increased propionate production by 11–23% ($P < 0.001$) and reduced acetate-to-propionate ratios by 15–17% ($P < 0.001$) relative to CTL diet, indicating a shift toward propionate-oriented fermentation, while gas kinetics showed 14–17% faster fractional fermentation rates for PC and CPC ($P < 0.001$), consistent with their higher fermentability and starch availability. Additionally, CH4 yield decreased by 16% with PC and by 30% with PS compared with the CTL ($P < 0.001$). Under Rusitec conditions, PC maintained total VFA production comparable to CTL (120 vs. 123 mM/day), increased propionate production by 14% ($P = 0.001$), reduced butyrate by 25% ($P < 0.001$), and substantially lowered ammonia-N concentrations ($P < 0.001$). Dry matter disappearance was comparable between PC and CTL, although PS showed markedly lower degradability ($P < 0.001$), reflecting compositional differences in fibre and lignin content. Daily gas production was maintained with PC but reduced with PS ($P = 0.045$), while CH4 production showed consistent numerical reductions (12–20%) for potato co-products compared with CTL, accompanied by modest improvements in hydrogen recovery efficiency. Temporal fermentation dynamics showed no significant treatment-time interactions for most fermentation parameters, indicating that the observed metabolic shifts persisted consistently throughout feeding cycles rather than representing transient post-feeding effects. These findings indicate that thermally processed potato co-products, particularly PC, show potential to replace cereal grains in vitro while maintaining fermentation activity and reducing methanogenesis. However, in vivo validation remains essential to confirm these results under practical feeding conditions.

Can corn in a dairy sheep ration can be replaced with cull carrots?

N. Merino[1,2], J. Giráldez[2], A. Díaz[1,2], C. Saro[1,2], I. Mateos[1,2], J. Mateo[1], I. Caro[3], M. J. Ranilla[1,2]
[1] Universidad de León, Producción Animal, Campus de Vegazana, s/n, 24007 León, Spain, [2] Instituto de Ganadería de Montaña, Finca Marzanas, 24346 Grulleros, Spain, [3] Universidad de Valladolid, Avda. Ramón y Cajal, 7, 47005 Valladolid, Spain

Spain is one of the main producers of fruits and vegetables in the EU, generating large amounts of horticultural waste that are discarded at different stages of the food supply chain. The use of these discarded products as feed ingredients for ruminants could help reduce both the environmental impact associated with their disposal and the feeding costs of livestock production. Cull carrots represent a potential alternative energy source in ruminant diets. The aim of this study was to evaluate the effect of replacing corn with cull carrots in the diet of dairy sheep on feed intake, live body weight, feed efficiency, and milk yield and composition. Two groups of ten lactating Assaf ewes on the second third of lactation were fed on two different isoproteic and isoenergetic diets (total mixed rations) for 28 days. The control group (CTL) received a total mixed ration ad libitum and the carrot group (CAR) received the same ration but corn was totally replaced by fresh cull carrots (160 g/kg DM) previously chopped in 1 cm pieces. Milk yield was recorded daily and milk samples were taken on days 1, 8, 15, 22 and 28 for chemical analysis: fat, protein, and lactose. Individually feed intake was daily recorded, using two automatic feeders (SmartFeed, C-Lock, USA) per group. Feed conversion ratio (FCR) was estimated by dividing the average daily dry matter intake by the average daily milk yield. Ewes were weighed at the beginning and the end of the trial, to determine body weight change. Total dry matter intake (DMI) and live body weight remained similar between experimental groups throughout the experimental period. No differences were observed between diets in milk yield over the 28-day period (2121 and 1961 g/day for CTL and CAR, respectively; $P > 0.05$), but a significant diet x day interaction was observed ($P < 0.05$). FCR was similar between both groups (1.15 and 1.30 g DMI/g milk for CTL and CAR, respectively; $P > 0.05$). No significant differences were detected for protein, fat or lactose concentration in milk ($P > 0.05$). However, a tendency for a diet x day interaction was observed for milk fat content from the 5 sampling days and was numerically higher in the CAR group (5.58 and 5.85% for CTL and CAR, respectively; $P = 0.05$). The results of the present study suggest that cull carrots can replace corn in the diet of dairy ewes without negatively affecting dry matter intake, milk yield, feed efficiency or overall milk composition during mid-lactation. These findings support the potential use of carrot as an alternative energy source in dairy ewe ration without compromising productive performance. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Valorization of agro-industrial by-products: effects of brewery spent grains and olive leaves on milk quality and sustainability indicators in grazing ewes

V. Bolletta[1], M. Pauselli[1], E. Lilli[1], M. Vispi[1], B. Valenti[1]
[1] University of Perugia, Department of Agricultural, Food and Environmental Sciences, Borgo XX Giugno 74, 06121 Perugia, Italy

Brewery spent grains (BSG) and olive leaves (OL) are agro-industrial byproducts rich in nutrients and phenolic compounds, often discarded as special wastes. Yet, their recovery as a feed ingredients for ruminants may offer both environmental and nutritional benefits. Indeed, polyphenols have gained interest for their ability to modulate ruminal metabolism, potentially improving microbial protein metabolism and milk quality, and the use of agro-industrial by-products could reduce the feed-to-food competition and reliance on imported commodities. Given the above, we hypothesized that the inclusion of BSG and OL to partially replace conventional cereal and pulses in a pelleted concentrate for grazing lactating ewes could influence animal performance, milk composition, coagulation properties, antioxidant capacity, fatty acid (FA) profile, rumen volatile fatty acids (VFA), and human-edible feed conversion efficiency (HEFCE). Twenty-two mid-lactation Comisana ewes were allocated to two homogeneous groups: a control group (CTRL; n=11), receiving 800 g/head/day of commercial pelleted feed, and an experimental group (TRB; n=11), receiving a pelleted feed containing 35% dried brewery spent grains and 7% dried olive leaves. Both groups grazed together for 8 h/day and received 450 g/head/day of alfalfa hay. After a 15-day adaptation period, individual milk yield and samples for chemical analyses were collected weekly over a 30-day experimental period. At the end of the trial, rumen content was collected using an esophageal probe. Data were analyzed using a mixed model to test the fixed effect of diet and sampling time, and their interactive effect (diet ´ sampling time) for performances and milk quality parameters. Diet was included as a fixed effect for VFA data. The animal was included as a random effect. Differences were considered statistically significant when $P \leq 0.05$. Tukey's test was used for multiple comparisons. Animal performance was not negatively affected by the TRB diet ($P>0.05$). Milk urea ($P \leq 0.05$) and somatic cell count ($P<0.001$) were lower in the TRB group, likely due to the higher polyphenol content of the TRB concentrate. Lactose was higher in TRB milk ($P \leq 0.05$) and rennet clotting time and curd firmness were improved ($P<0.001$). Milk total saturated FA decreased, whereas mono- and poly-unsaturated FA increased in TRB milk ($P<0.001$). Specifically, stearic acid (C18:0) increased ($P<0.05$), likely reflecting both a greater dietary supply of this FA and increased ruminal biohydrogenation due to the higher intake of C18:3 n-3 and C18:2 n-6 in the TRB diet. Also, C18:3 n-3 and C18:2 n-6 increased in TRB milk. Moreover, C18:1 isomers and biohydrogenation intermediates including rumenic acid (C18:2 c9t11) increased ($P \leq 0.05$), suggesting alterations in ruminal biohydrogenation pathways. The n-6/n-3 ratio increased for TRB milk but remained within recommended nutritional limits. Atherogenic and thrombogenic indices were significantly reduced ($P<0.001$) in the TRB group compared with CTRL. Milk antioxidant capacity was not affected by diet ($P>0.1$). Propionate concentration in rumen content increased ($P=0.04$), indicating possible alterations in VFA metabolism. The HEFCE improved in the TRB diet. In conclusion, our findings suggest that BSG and OL improved milk technological properties and lipid profile without impairing animal performance. Moreover, the improved HEFCE suggests a potential reduction in feed-to-food competition and a lower environmental impact, supporting the use of these by-products within circular livestock production systems.

Sesame Seed Meal as a Local Alternative Protein Source in Lamb Diets: Effects on Animal Performance and Meat Quality

A. Natalello[1], M. S. Cannone[1], M. Musati[1], S. Privitera[1], F. Mangano[1], A. Bertino[1], M. Lanza[1], G. Luciano[1], L. Biondi[1], A. Priolo[1], G. Mangione[1]

[1] University of Catania, Via Santa Sofia 100, 95123 Catania, Italy

The feedstuff market currently faces significant challenges due to price volatility and recurrent shortages of key ingredients. These issues are particularly evident for high-protein feed sources such as soybean meal and other conventional feed ingredients. Consequently, there is increasing interest in identifying locally available alternative protein sources that are affordable and readily accessible, while maintaining animal health and productivity and reducing the environmental impact of feed supply chains. In this context, the present study aimed to evaluate the effects of including sesame (Sesamum indicum L.) seed meal, produced in the Mediterranean area, in lamb diets on animal performance and meat quality. Sixteen male weaned lambs (40 days old; 15.3 ± 0.51 kg body weight) were selected from the farm flock and randomly assigned to two experimental groups. Two isoenergetic and isoproteic diets were formulated. The first group was fed a conventional diet (CON) consisting of maize (43%), alfalfa hay (32%), soybean meal (20%), molasses (3%), and a vitamin–mineral premix (2%). The second group received a similar diet in which 10% sesame seed meal (SES) replaced soybean meal. After 50 days of feeding, all lambs were slaughtered at a local slaughterhouse. Carcasses were weighed and stored at 4 °C for 24 h. Subsequently, samples of the Longissimus dorsi muscle were collected for further analyses. The partial replacement of soybean meal with sesame seed meal did not affect voluntary feed intake ($P > 0.05$). Ruminal pH and carcass characteristics also showed no significant differences between the two experimental groups ($P > 0.05$). Likewise, meat quality traits related to moisture retention — such as water-holding capacity, drip loss, and cooking loss — as well as color parameters, were not significantly affected by diet ($P > 0.05$). The total contents of saturated (SFA), monounsaturated (MUFA), and polyunsaturated fatty acids (PUFA) in intramuscular fat were not influenced by sesame inclusion ($P > 0.05$). However, the concentration of health-promoting fatty acids, particularly vaccenic acid (C18:1 t11) and rumenic acid (C18:2 c9,t11), was substantially increased in lambs fed the diet containing 10% sesame seed meal ($P < 0.05$). In contrast, the SES diet resulted in a reduction in the proportion of odd- and branched-chain fatty acids (OBCFA). In conclusion, sesame seed meal can be considered a promising alternative protein source for lamb diets, allowing partial replacement of soybean meal without negatively affecting animal performance, carcass traits, or meat quality. Moreover, its inclusion improved the profile of health-promoting fatty acids in intramuscular fat. These findings support the potential use of sesame seed meal as a sustainable feed ingredient in Mediterranean livestock systems. This study was carried out within the Agritech National Research Center and received funding from the European Union Next-GenerationEU (PIANO NAZIONALE DI RIPRESA E RESILIENZA (PNRR) – MISSIONE 4 COMPONENTE 2, INVESTIMENTO 1.4 – D.D. 1032 17/06/2022, CN00000022). Replacing soybean products with dried brewer's grains and sunflower meal in light lambs' diets: implications on meat quality and fatty acid profile.

J. L. Lema-Hurtado[1], J. M. Arroyo[1], T. De Evan[1], A. Recalde[1], J. Mateo[2], M. Dehnavi[2], M. D. Carro[1]
[1] Universidad Politécnica de Madrid, Departamento de Producción Agraria, ETSIAAB, Ciudad Universitaria, 28040 Madrid, Spain, [2] Universidad de León, Departamento de Higiene y Tecnología de los Alimentos, 24071, Campus de Vegazana, s/n, 24071 León, Spain

The use of agro-industrial by-products in animal feeding is increasing due to their contribution to farms sustainability and circular economy in the livestock sector, although their impact on the quality of animal products must be evaluated. This study assessed the effect of replacing soybean meal and hulls with dried brewer's grains and sunflower meal in the concentrate of light fattening lambs on meat pH, chemical composition, fatty acid (FA) profile, color and lipid oxidation measured as TBARS (thiobarbituric acid reactive substances) concentration. Twenty-two male Assaf lambs (15.5 ± 0.34 kg body weight) were divided in two homogeneous groups and each was assigned to one dietary treatment. Two iso-nitrogenous (145 g crude protein/kg) and iso-energetic (0.98 units for meat production/kg) concentrates were formulated: a high-cereal concentrate containing soybean meal and hulls (control) and a concentrate (BGSF) in which both soybean products were totally replaced with dried brewer's grains (16.1%) and sunflower meal (16.5%). All lambs were fed ad libitum concentrate and barley straw and were slaughtered at about 25 kg body weight. Meat pH was measured in the longissimus thoracis and semitendinosus muscles at 0 and 24 h post-mortem, and both chemical composition and fatty acid (FA) profile were analyzed in a sample of longissimus lumborum after 24 h of chilling. In addition, changes in color and lipid oxidation (TBARS concentrations) were assessed over 6 days of refrigerated storage in a sample of longissimus lumborum. Two lambs from the control group had health problems and were withdrawn from the experiment. Data on meat pH, chemical composition and FA profile were analyzed by analysis of variance with the fixed effect of concentrate. Meat color and lipid oxidation data were analyzed as a mixed model with repeated measures, in which the effects of concentrate, time (0, 3 and 6 days) and their interaction were considered fixed, and the effect of lamb was considered random. The type of concentrate had no effect ($P > 0.05$) on meat pH, chemical composition (moisture, ash, protein and fat content) and content in total saturated FA and monounsaturated FA. However, lambs fed the BGSF concentrate had greater content of polyunsaturated FA (436 vs. 356 mg FA/100 g meat; $P = 0.034$), indicating a healthier FA profile. Feeding the BGSF concentrate also increased meat content in n-6 FA (384 vs. 307 mg /100 g meat; $P = 0.025$) and the ratio n6/n3 (13.0 vs. 11.6; $P = 0.003$). Concentrate type had no effect ($P > 0.05$) on either color or lipid oxidation of meat over storage and no interaction concentrate x storage time was detected ($P = 0.740$). In conclusion, replacing soybean products with dried brewers' grains and sunflower meal did not negatively affect meat quality traits and slightly improved its polyunsaturated FA content, supporting the use of these feeds as sustainable alternatives in lamb feeding.

Long-term impact of avocado seed (Persea Americana L.) inclusion during early-life on ruminal fermentation, blood parameters, fertility and milk yield performance in Murciano-Granadina goats

A. Sánchez-García[1], M. Romero-Huelva[1], D. Yáñez-Ruíz[1], A. I. Martín-García[1]
[1] Estación Experimental del Zaidín (CSIC), C/ Profesor Albareda 1, 18008 Granada, Spain

Spain is the leading avocado producer in the European Union [1]. The guacamole industry generates substantial quantities of by-products, with seeds (AS) accounting for approximately 30% of the total fruit weight. [2]. Previous studies by our research group have demonstrated that AS is a high-energy ingredient due to its high starch content with degradation profiles comparable to those of cereals commonly used in ruminant diets [3,4]. However, its use in ruminant nutrition remains controversial due to potential toxic effects. Therefore, it is essential to evaluate its safety and efficacy through in vivo under real production conditions. For this purpose, 32 post-weaning Murciano-Granadina goats (14.2 ± 0.291 kg) were divided into two experimental groups: one control group (CTL) fed with a commercial concentrate, and a treatment group (AVC) fed with a commercial concentrate with an 11% of inclusion of AS (dry matter basis). Blood and live weight were collected from 20 goats per group at 75 (S1), 120 (S2) and 240 (S3) days of age. Additionally, ruminal fluid samples were obtained during the S2 and S3 periods. To characterize the dietary effect on animal productivity, individual milk yield and composition were monitored. Statistical analyses were performed using SPSS and R software. One-way ANOVA was conducted using GLM for single-point measurements and LMM for body weight and blood parameters. Significance was set at $P < 0.05$. No significant differences were found between treatments in animal body weight. Regarding the rumen fluid parameters at S2, the concentrations of isobutyrate (2.60 vs. 1.70 mol/100 mol, $P = 0.002$) and isovalerate (2.83 vs. 1.52 mol/100 mol, $P= 0.001$) were higher in the AVC compared to the CTL. Conversely, the AVC showed lower total short-chain fatty acids concentration (34.3 vs. 51.2 mmol/L, $P = 0.001$) and butyrate molar proportion (11.3 vs. 13.8 mol/100 mol, $P = 0.002$). By S3 sampling, no significant differences were detected in any ruminal fermentation parameters. Regarding blood parameters, no significant main effect of diet was observed, except for total cholesterol (TC), where the AVC treatment showed lower overall levels than CTL. A significant diet × time interaction was revealed for lipid fractions and NEFA. Specifically, both TC and HDL-cholesterol ($P < 0.001$) showed a marked decrease in the AVC group by the S3 period, resulting in lower final values compared to the CTL group. Similarly, NEFA levels displayed a significant interaction ($P = 0.021$), driven by an increase in the AVC group at S2 that was not observed in the CTL group. Fertility rates improved in AVC compared to the CTL (89.7 vs. 65.2 %). While milk yield and composition remained unaffected by the treatment, the somatic cell count was reduced in AVC goats both postpartum (135 vs. 343 10^3/ml, $P = 0.005$) and at the lactation peak (222 vs. 489 10^3/mL, $P = 0.005$). Despite the observed differences in ruminal fermentation, animal growth and milk yield remained unaffected by the treatments. Notably, the AVC diet suggested an improvement in mammary health. Furthermore, the increased fertility in AVC may be linked to the observed reduction in circulating TC, which could stimulate progesterone synthesis [5]. These beneficial effects, coupled with the absence of toxicity, position the AS as a functional and sustainable ingredient in ruminant nutrition. [1] FAOSTAT. 2024; [2] Rojas-García, A. 2022. Adapting Dairy Cow Diets Toward a More Resilient and Efficient System by Using Sorghum Silage

M. M. Shaklouf[1,2], N. Prat[1], M. Terré[1]
[1] IRTA, Ruminant Production, Torre Marimon Carretera C-59, Km. 12,1 Caldes de Montbui, 08140 Barcelona, Spain, [2] Cairo University, Animal Production, 1 Gamaa Street, 12613 Giza, Egypt

Water scarcity and climate change are constraining dairy production by reducing key feed resources availability, such as corn silage, which—despite its high yield and energy content—is increasingly challenged by drought and mycotoxin risks. This drives interest in more resilient forage alternatives. Sorghum (Sorghum bicolor L.) offers strong drought and salinity tolerance, requires less water and fertilizers, and allows multiple harvests, making it a promising alternative. This study aimed to evaluate the impact of replacing corn silage with sorghum silage in dairy cow diets. A total of 80 Holstein cows (parity: 1-6; body weight (BW): 703 ± 8.4 kg; milk yield: 37.6 ± 0.98 kg/d; days in milk (DIM): 194 ± 9.9 days) located in 4 different pens were blocked by parity, DIM and milk yield, and randomly assigned to 1 of 2 treatments: CS (corn silage–based diet; 18.7% CP, 1.63 Mcal NEl/kg, 30.5% starch, and 25.6% aNDF, on DM basis) or SS (sorghum silage-based diet; 18.7% CP, 1.65 Mcal NEl/kg, 28.7% starch, and 26.8% aNDF, on DM basis). Over 60 d, BW, milk yield and composition were recorded daily by AfiFarm system (V 5.2.1 A-DU). Feed intake (FI) was measured at pen level to estimate feed efficiency (FE). Additional milk samples were collected biweekly and analyzed by NIRS (MilkoScan) for fat, protein, lactose, solids non-fat, somatic cell count, and urea. Data were analyzed using repeated measures in SAS (V. 9.4) considering one-previous week average pre-trial values as covariates and including block effect. No differences in BW or BW change were noted between treatments. Cows in SS tended ($P = 0.08$) to produce more milk than CS cows during the first 5 weeks, with no differences thereafter. Milk AfiLab system data showed that milk fat concentration increased ($P < 0.03$) in SS during the first 5 weeks of study compared with CS cows, whereas fat yield remained greater ($P < 0.04$) in SS than CS throughout the trial, except for the first week. The use of either corn or sorghum silage did not affect milk protein content, but milk protein yield tended ($P = 0.09$) to be greater in SS than in CS cows, mainly during the first 4 weeks ($P < 0.04$), consistent with the greatest milk yield. Milk Milkoscan analysis revealed a greater ($P < 0.01$) milk fat percentage in SS than in CS cows at the 5th sampled week, probably due to the slight differences in starch and fiber contents in the diet. Similarly to AfiLab system data, no variations were detected in milk protein content. However, milk urea concentration was numerically greater in SS than CS cows throughout the study, but significantly greater ($P < 0.01$) at week 4, suggesting an excess of CP in their diet. Feed intake was similar in both treatments except for the 5th week that was lower ($P < 0.05$) in SS compared with CS cows. Following the same trend, FE did not differ between treatments, but it tended ($P = 0.07$) to be lower in CS compared with SS cows during the 5th week. The lower milk yield and similar FI during the first weeks of study in CS compared with SS cows suggest that the adaptation to the new diet for CS cows was more challenging for the digestive system than for SS cows, probably due to the greatest starch content in CS diet. Afterwards, both diets performed similarly without compromising FE or milk quality. In conclusion, sorghum silage represents a resilient alternative to corn silage that maintains dairy cows' performance and milk quality.

Wheat Silage and Hempseed Cake as Sustainable Alternatives in the Feeding of Dairy Cows

A. Latrofa[1], N. Guzzo[1], S. Currò[1], N. Amalfitano[2], J. Bisello[1], S. Arango[1], C. Sartori[2], A. Simonetto[2], L. Bailoni[1]
[1] University of Padova, Comparative Biomedicine and Food Science (BCA), Viale dell'Università 20, 35020 Legnaro, Padova, Italy, [2] University of Padova, Agronomy, Food, Natural resources and Environment (DAFNAE), Viale dell'Università 20, 35020 Legnaro, Padova, Italy

In temperate regions, corn silage and soybean meal are key components of dairy cow diets, due to their high nutritional value. However, climate change, increasing mycotoxin risk, and declining European self-sufficiency are challenging their sustainability and safety. Consequently, interest is growing in resilient alternatives such as autumn–winter forages and oilseed co-products, although evidence regarding their combined use in dairy cows' diets remains limited. This study aimed to evaluate the effects of replacing corn silage with wheat silage and soybean meal with pelleted hempseed cake (Cannabis sativa L.) on productive performance, milk quality, behavioural activity and health in lactating dairy cows. A crossover trial was carried out at the experimental farm of the University of Padova (Italy). Four primiparous Italian Simmental cows (DIM: 148 ± 85; milk yield: 24 ± 5 kg/d) were assigned to two balanced groups (G1 and G2) and housed in individual pens. The study followed a 2 × 2 crossover design over 8 weeks. After a 1-week adaptation phase, cows were subjected to two experimental periods (3 weeks for each) separated by a 1-week washout period to minimize carryover effects. During period 1 (weeks 2-4), G1 received the conventional corn silage-soybean meal diet (CTR), routinely used on the farm, whereas G2 received the experimental diet based on wheat silage and hempseed cake (WSHS). Diets were reversed in period 2 (weeks 6-8). Both diets were formulated to be isoenergetic and isonitrogenous, averaging (% on DM): crude protein 15.05 ± 0.51, neutral detergent fiber 35.86 ± 1.74, starch 19.17 ± 0.75, and 1.47 Mcal/kg net energy. During each experimental period, milk, blood and rumen samples were collected weekly (3 samples per period, 6 per variable overall). Behavioural data were recorded through neck collars (SenseHub™, Allflex), providing 21 daily records per period for each variable. Data were analysed by ANOVA using the MIXED procedure of SAS. Results showed that DMI and milk yield were higher in cows fed WSHS (+2.36 kg DM, +1.38 kg/d; P<0.001), whereas feed efficiency was lower compared with CTR diet (-7.63%; P<0.001). The 4% Fat-corrected milk was not affected by the treatment. Milk fat, protein, and urea nitrogen were not influenced by the diet. Milk from cows fed WSHS had lower SFA (68.12 vs. 69.62%; P<0.01) and higher total PUFA (5.49 vs. 4.19%; P<0.001), including higher PUFA n-6 content (4.80 vs. 3.69%; P<0.001), resulting in a reduced n-6/n-3 ratio (6.98 vs. 7.40; P<0.01). Blood glucose, non-esterified fatty acid, aspartate aminotransferase were not affected by treatment. However, β-hydroxybutyrate was lower in cows fed WSHS diet (0.45 vs. 0.52 mmol/L; P<0.05), while γ-glutamyl transferase tended to increase (24.20 vs 25.10 U/L, P=0.09). Similarly, rumen pH, ammonia nitrogen, and total volatile fatty acid profile were unaffected by diet. Among behavioural traits, overall activity was lower in cows fed the WSHS diet (305.1 vs. 317.6 min/d; P<0.001), whereas rumination and eating times did not differ between treatments. In conclusion, wheat silage and pelleted hempseed cake could represent strategic alternatives to conventional feeds, improving milk fatty acid composition without compromising productivity or health. Improving the nutritional value of canola, flax, and wheat straw to beef cattle with calcium hydroxide treatment

C. Ross[1], G. Ribeiro[1], G. Penner[1]
[1] University of Saskatchewan, Animal and Poultry Science, 51 Campus Drive, S7N 5A8 Saskatoon, Canada

Forage production and management remain persistent challenges for livestock producers, where drought and adverse weather events such as hail frequently reduce yields and constrain forage availability. Developing strategies to enhance crop residue utilization offers an opportunity to reduce reliance on traditional forages, both during periods of scarcity and in years of favorable crop production. The objective of this study was to evaluate the effect of treating canola, flax, and wheat straw with calcium hydroxide on dry matter intake (DMI), ruminal pH, the concentration of ruminal short-chain fatty acids (SCFA), fractional rate of neutral detergent fiber passage (Kp) and degradation (Kd), and nutrient digestibility. Six ruminally canulated heifers were used in a 6 × 6 Latin square design with a 3 × 2 factorial treatment structure. Treatments included wheat (WS), canola (CS), or flax (FS) straw included at 40% of the dietary dry matter (DM). Straw sources were either treated with calcium hydroxide (CH) or limestone (CTL) as a control. For treatment, straw was hydrated to 50% moisture, combined with either CH or CTL at 5% of the DM weight, and stored for 24 to 48 h prior to feeding. Experimental periods lasted 24 d, with 14 d of dietary adaptation and 10 d of data and sample collection. Samples collected included feed and refusals, ruminal pH, ruminal fluid, ruminal digesta, and total fecal output. Data were analyzed using the GLIMMIX procedure of SAS 9.4 with fixed effects of straw type, calcium treatment, the straw type × calcium treatment interaction, and period. No interactions between straw type and calcium treatment were observed ($P \geq 0.13$), thus only main effects are discussed. Heifers consuming CH treated straw had 13.4% greater DMI than those consuming CTL treated straw (7.4 vs. 6.5 kg; $P < 0.01$). Dry matter intake was greater for WS and FS ($P < 0.01$) than CS. No effect of CH treatment was observed for ruminal pH ($P \geq 0.41$), but heifers fed CS had the greatest mean ruminal pH and those fed FS had the lowest ($P < 0.01$). Total ruminal SCFA concentration was 13.4% greater for heifers fed CH treated straw over CTL (124.9 vs. 110.1 mM; $P < 0.01$) and was less for heifers fed CS compared to WS and FS ($P < 0.01$). Use of calcium hydroxide increased the NDF Kp from 1.52%/hr (CTL) to 2.1%/hr (CH; $P = 0.02$) with no effect of straw treatment ($P = 0.12$). There was no effect of treatment on Kd ($P \geq 0.35$). Dry matter digestibility increased by 5.4% (57.8 vs. 54.8%; $P = 0.03$) and gross energy digestibility increased by 4.6% (61.4 vs. 58.7%; $P = 0.02$) for CH compared to CTL. A tendency was observed for greater organic matter (OM) digestibility in the CH treatment compared to CTL ($P = 0.08$). No effect of calcium hydroxide treatment was observed for ash-free neutral detergent fiber (aNDFom), or acid detergent fiber (ADF) digestibility ($P \geq 0.22$). The DM digestibility was greater for WS and FS relative to CS ($P < 0.01$). Gross energy digestibility and aNDFom digestibility were greatest in the WS treatment ($P < 0.01$). Acid detergent fiber digestibility was greatest for the WS treatment, intermediate for the FS treatment, and least for CS ($P = 0.02$). Calcium hydroxide treatment increased dry matter intake, total ruminal SCFA concentration, the fractional passage rate of aNDFom, and apparent dry matter and gross energy digestibility, regardless of straw type. Thus, these results suggest that calcium hydroxide treatment could serve as a practical approach to improve straw quality.

From waste to worth: Chemical, physical and functional properties of spent mushroom substrates with implications for ruminant nutrition

R. Khiaosa-Ard[1,2], L. Spoljaric[3]
[1] University of Veterinary Medicine, Vienna, Center for Animal Nutrition and Welfare, Veterinärplatz 1, 1210 Vienna, Austria, [2] BOKU University, Institute of Animal Nutrition, Livestock Products, and Nutrition Physiology, Muthgasse 11, 1190 Vienna, Austria, [3] FH Wiener Neustadt, Biotech Campus Tulln, Konrad-Lorenz-Straße 10, 3430 Tulln, Austria

Spent mushroom substrates (SMS) are the residual biomass remaining after mushroom cultivation. SMS uniquely combines two abundant natural polymers namely chitin (a fungal cell-wall component) and lignocellulose from the sawdust growing medium, each with applications in animal nutrition. We characterized the chemical, physical, and functional properties of SMS from shiitake, king oyster, and oyster mushrooms. Thirty-six SMS samples were collected over four consecutive weeks (three replicates per week; 12 per mushroom) from a local producer in Vienna. We assessed chemical composition, fat-binding capacity, antioxidant properties, total phenolic content, and in vitro ruminal degradability. Across mushrooms, SMS was low in crude protein (3–5%) and ether extract (0.1–0.3%) but high in fiber (69–84% neutral detergent fiber) on a dry matter basis. Shiitake SMS showed greater ruminal degradability (58% potentially degradable organic matter vs. 42–43% for oyster and king oyster ($P<0.01$), consistent with its lower lignin content (8.8% vs. 11–14%). It also had higher total phenolic content and antioxidant capacity ($P<0.01$) All SMS bound oil at 2.7–3.2 times their weight, with oyster SMS showing the highest value $P<0.05$). Overall, shiitake SMS outperformed oyster and king oyster SMS on several criteria. These findings highlight SMS as a promising, harvestable resource for applications in animal nutrition, especially for ruminants. There is still the need to address remaining technical gaps and to evaluate feed safety to support decisions on integrating this circular biomass into the food chain.

Exploring the use of fresh apples in dairy cow diets

M. Terré[1], N. Prat[1], D. Sabrià[1], J. M. Palma-Hidalgo[1]
[1] IRTA, Ruminant Production, Torre Marimon, 08140 Caldes de Montbui, Spain

Non-saleable fresh apples from proximity orchard could be used in dairy cow diet as a sugar source rapidly digested in the rumen, which may be used by rumen microbes to grow. To explore the use of fresh apples in dairy cow diets, 2 studies were performed. In the first study, a total of 7 primiparous and 7 multiparous lactating Holstein dairy cows (182±87.4 DIM, 27.8±5.51 kg milk/d) were fed either a control diet (15.8% CP, 1.64 Mcal NE/kg DM, CTRL) or a diet with 2 % DM of apples (15.5% CP, 1.64 Mcal NE/kg DM, APP). Feed intake, milk yield and feed efficiency were daily recorded for a 52-d period. During the last week of the study, milk samples were obtained for milk quality analysis, and rumen fluid for 2 consecutive days were sampled to determine rumen pH and pooled for VFA and microbiota analysis. In a second study, a total of 22 primiparous and 52 multiparous lactating Holstein dairy cows (190±98.4 DIM, 30.4±6.86 kg milk/d) were fed either a control diet (16.5% CP, 1.59 Mcal NE/kg DM CTRL) or a diet with 2 % DM of apples (16.3% CP, 1.60 Mcal NE/kg DM APP) for a period of 37 days. Milk yield, feed intake and feed efficiency were daily recorded, and milk samples obtained every 2 weeks. At day 36, rumen samples were collected from 4 cows per treatment and incubated in vitro with their own diet (plus an intermediate diet with half the amount of apple content) for gas production measurements and VFA determination. In study 1, energy-corrected milk, dry matter intake, and feed efficiency were similar in both treatments. Milk composition was similar in both treatments with the exception of milk urea concentration, which was lower ($P < 0.05$) in APP than in CTRL cows (0.24 vs 0.32 ± 0.158 g/L, respectively). Rumen VFA concentrations and proportions were similar in both treatments, except for a trend ($P = 0.08$) of a lower propionic acid concentration in APP than in CTRL cows. Chao1 and Shannon indexes for the prokaryotic community were greater ($P < 0.05$) in the rumen of APP than in CTRL, suggesting a more diverse rumen ecosystem. Taxonomic analysis revealed a greater relative abundance of Bacteroidales and lower Lachnospirales order in CTRL than APP cows, but the overall community composition did not differ across treatments based on a PERMANOVA analysis. In the second study, a decrease was observed ($P < 0.005$) in DMI in APP compared to CTRL cows (24.0 vs 25.5 ± 0.42, respectively) resulting in an improvement ($P = 0.05$) on feed efficiency (1.49 vs 1.43 ± 0.030, respectively). Total gas, methane, CO2 and the concentration of total VFA and individual VFA after in vitro incubation were unaffected by the treatment. Non-saleable fresh apples can be used at 2% of the dairy cow diets without performance impairment and rumen fermentation shift.

Implementation of a short-term palatability test to evaluate dairy cows preference for Carinata meal

L. Dicks[1], Y. Roman-Garcia[2], G. F. Schroeder[2]
[1] Cargill Animal Nutrition and Health, Global Innovation Center, Veilingweg 23, NL-5334LD Velddriel, Netherlands, [2] Cargill Animal Nutrition and Health, Global Innovation Center, 10383 165th Avenue NW, MN 55330 Elk River, United States

Carinata meal from Brassica Carinata is a high-protein byproduct from extraction of oilseed, representing a sustainable feed ingredient supporting circular agriculture. Its nutritional value is comparable to soybean and canola meals; however, the presence of antinutritional factors such as glucosinolates and a higher content of erucic acid may limit its inclusion in dairy cows' diets by reducing palatability and limiting intake. The objective of this study was to assess the palatability effects of replacing 10% of canola meal with carinata meal in a concentrate, implementing a short-term methodology evaluating dairy cows' preference. Eight rumen cannulated Holstein Friesian cows (229.4 ± 92.1 days in milk; 38.6 ± 6.4 kg/d milk) were housed in tie-stalls and fed a lactating cow diet, formulated for a 740 kg cow producing 32 kg/d of milk. The concentrate included barley (22.8%), high sugar beet pulp (19.0%), canola meal (15.2%), and 7.6% each of corn, wheat, low-sugar beet pulp, and lupin, plus full-fat soybeans (6.8%), soybean meal (3.8%), calcium carbonate (1.1%), and salt (0.8%). Carinata meal contained 90.2% dry matter (DM), 45.6% crude protein, 2.0% ether extract, 8.4% ash, 27.3% neutral detergent fiber, and 29.3 µmol/g DM of glucosinolates. Each cow received 10.4 kg concentrate per day (representing 14.8% of the diet (as fed)), with 4.4 kg mixed into the partial mixed ration (PMR) and 6 kg offered separately in four 1.5 kg portions containing either treatment A (0% of canola meal replaced by carinata meal), treatment B (10% of canola meal replaced by carinata meal), or treatment C (90% of canola meal replaced by carinata meal as negative control). Palatability test consisted in offering the concentrate twice daily for three minutes in paired buckets with randomized left/right positions, reversed between morning and afternoon to control for side preference. To avoid confounding effects of hunger, cows received treatment after receiving their PMR diet. Treatment A and B were offered in the first two experimental days, followed by treatment B and C during the subsequent two days. Feed intake was recorded, and observations of time spent eating and number of visits were recorded by observational scoring. Data was analyzed using mixed effects models (lme4 package in R) including fixed effects of treatment and bucket position and random effects of cow and day. For the positive control (A vs. B), inclusion of 10% carinata meal did not affect feed intake, time spent eating, or number of visits. Bucket position influenced intake ($P = 0.02$), number of visits ($P < 0.01$) and time spent eating ($P = 0.03$) with cows showing a consistent preference for the left bucket. However, no interaction between treatment and position was detected, indicating that treatment effects were independent of bucket position. For the negative control (B vs. C), 90% carinata inclusion reduced intake ($P = 0.02$), time spent eating ($P = 0.01$) and number of visits ($P = 0.01$) relative to the 10% inclusion. Bucket position affected intake, but no treatment and bucket position interaction was observed. These findings indicate that cows differentiated treatments based on palatability rather than positional bias, confirming the functionality of the palatability test used in this experiment. Substituting 10% of canola meal with carinata meal did not reduce palatability when feeding a concentrate, supporting its potential as a sustainable protein source in dairy rations. Future studies should investigate higher inclusion levels and the long-term effects on intake and performance.

Protein value for ruminants of brewer's grains from Spanish breweries

J. L. Lema-Hurtado[1], M. D. Carro[1], T. De Evan[1], I. Macarrón[1], A. Cabezón[1], A. Recalde[1], A. Alcamí-Aguado[1], J. M. Arroyo[1]

[1] Universidad Politécnica de Madrid, Departamento de Producción Agraria, ETSIAAB, Ciudadela Universitaria, 28040 Madrid, Spain

Brewer's grains (BG) are the main by-product of the brewing industry and, due to their high content in crude protein (CP) and high-degradable fiber are commonly used in ruminant feeding. However, some factors, such as the raw materials and the processing methodology employed in beer production, may influence both the chemical composition and the protein value of BG. Therefore, the aim of this study was to determine the protein value of 41 samples of BG obtained from different industrial and craft Spanish breweries. Samples were dried (40ºC) and analyzed for chemical composition. In addition, samples of each BG sample were incubated in quadruplicate with buffered sheep ruminal fluid for 12 h to determine CP rumen degradability (CPRD). The intestinal digestibility of the rumen-undegraded CP fraction (CPID) was determined using the three-step in vitro procedure, which included the incubation with pepsin solution for 1 h and pancreatin solution for 24 h. Protein value (PDIA, PDIN and PDIE) of each sample was estimated using the INRA-2007 equations and the in vitro CPRD and CPID values. For each chemical fraction analyzed, mean, minimum and maximum values, as well as the coefficient of variation (CV), were calculated. In addition, the relationship between CPRD and CPID was evaluated by linear regression analysis using the PROC REG procedure of the SAS statistical software. Content of CP ranged from 16.7 to 35.1% dry matter basis (average 25.8%), in agreement with INRA values (19.0 – 37.5%; average 26.2%). The CPRD showed high variability (coefficient of variation (CV) = 43.9%), ranging from 18.0 to 78.5% (average 36.5%), whereas CPID was less variable (10.4% CV) and ranged from 56.3 to 91.8% (average 82.2%). The average CPRD was lower than the average value of 44.0% reported by INRA for a rumen passage rate of 6%, likely due to the shorter incubation time in the rumen used in the present study (12 h; 8.3% passage rate). In contrast, the average CPID was similar to the 84.0% value reported by INRA. Average values of PDIA, PDIN and PDIE (15.3, 23.1 and 21.8% dry matter, respectively) were greater than those reported by INRA (13.7, 19.4 and 17.7% dry matter), which could be related to differences in the methodology used to estimate CPRD, as previously discussed. A strong linear negative relationship was observed between the CPID and CPRD values (CPID = 0.966 – 0.481· CPRD; R_2 = 0.83; SEM = 0.0395; $P < 0.001$), indicating that samples with higher ruminal degradability tended to have lower intestinal digestibility of the undegraded CP fraction. This highlights a trade-off between the amount of bypass protein and its intestinal digestibility, because as ruminal degradability increases, the proportion of bypass protein decreases, and its intestinal digestibility is reduced. Thus, BG constitute a valuable source of bypass protein, contributing to the supply of metabolizable protein in ruminant diets. The results indicate high variability in protein value of BG, particularly in CPRD. In practice, determining the rumen degradability of BG-CP is recommended before its inclusion in ruminant diets.

Ensiling discarded tomatoes with dried beet pulp, almond hulls or wheat bran: effects on silage quality

A. Alcamí-Aguado[1], J. M. Arroyo[1], T. De Evan[1], J. L. Lema-Hurtado[1], S. Salazar[1], W. Santos[1], A. Recalde[1], F. Bacha[2], M. D. Carro[1]

[1] Universidad Politécnica de Madrid, Producción Agraria, Av. Puerta de Hierro 2, Moncloa-Aravaca, 28040 Madrid, Spain, [2] NACOOP S.A., Av. Cerro del Águila 3, 28703 San Sebastián de los Reyes, Spain

A considerable proportion of total tomatoes production is lost during postharvest grading because they do not meet the high quality standards of consumers. Discarded tomatoes contain nutrients, but their high moisture content limits their use in animal feeding. Ensiling could be an effective alternative for preserving discarded tomatoes, although co-ensiling with high dry matter (DM) raw materials is necessary to improve ensiling capacity. This study evaluated the ensiling potential of mixtures of discarded tomatoes with dried beet pulp (BPT), almond hulls (AHT) or wheat bran (WBT). Each mixture was prepared to reach approximately 38-40% DM and ensiled in vacuum bags (500 g mixture/bag; 4 bags/treatment). Bags were stored at room temperature in darkness for 90 days before opening and analysis of chemical composition, pH, concentrations of volatile fatty acids, NH3-N, lactic acid, and microbial quality of silages. Data were analyzed using the software R, applying a linear model (ANOVA) with treatment as a fixed effect. Adjusted means were obtained using emmeans library, and comparisons between treatments were performed using Tukey's test. Pre-ensiling DM content was 41.6, 39.6 and 38.2% for AHT, WBT and BPT mixtures, respectively. No gas or effluent was detected in any silage, and all silages had good odor. At opening, DM content was higher ($P<0.05$) in WBT and BPT (35.4 and 34.3%, respectively) than in AHT (31.7%). Silages differed in their chemical composition (all data expressed on DM basis). Ash content was higher ($P<0.05$) in AHT (13.4%) than in WBT and BPT (7.36 and 5.81% DM, respectively). The WBT silage had the greatest protein and ether extract content (18.0 and 6.85%), whereas BPT and AHT had lower values (13.0 and 7.50% of protein; 2.43 and 3.85 % of ether extract). Neutral detergent fiber was highest ($P<0.05$) in BPT silages (47.5%), followed by AHT and WBT (44.2 and 38.5%, respectively), whereas acid detergent fiber and lignin were higher ($P<0.05$) in AHT (33.2 and 15.7%) than in WBT (14.3 and 2.56%) and BPT (25.0 and 3.90%). Fermentation characteristics also differed among mixtures. The pH was higher ($P<0.05$) in AHT (4.49) than in WBT and BPT (4.05 and 4.15, respectively), although all values were within the range considered adequate for a stable silage. DM losses were greater ($P<0.05$) for AHT (29.9%) than for WBT and BPT (13.5 and 16.8%). No propionic, butyric, isobutyric, isovaleric or valeric acids were detected in any silage. Acetic acid concentration was higher ($P<0.05$) in AHT (30.6 g/kg DM) than in WBT and BPT (25.4 and 22.5 g/kg DM, respectively). Concentration of NH_3-N was higher ($P<0.05$) in WBT (1.76 g/kg DM) than in AHT and BPT (0.49 and 0.47 g/kg DM, respectively), likely reflecting its higher protein content. No presence of pathogenic bacteria (Enterobacterias spp, Escherichia coli, Listeria monocytogenes, Salmonella spp., Staphylococcus coagulase+) were detected in any silage. Clostridium perfringens counts were low and did not differ ($P>0.05$) between treatments (3.43, 2.21 and 2.04 log colony forming units (CFU)/g for WBT, AHT and BPT, respectively). However, yeasts and molds counts were higher ($P<0.05$) in AHT (16.0 and 2.21 log CFU/g, respectively) than in WBT (12.3 and 1.98 log CFU/g, respectively) and BPT (5.65 and 2.04 log CFU/g, respectively). All treatments showed good ensilage capacity, with distinct nutritional and fermentation characteristics. Therefore, the choice of the mixture will depend on the nutritional profile desired and the availability of the raw materials.

In vitro gas production kinetics of different conventional and non-conventional feeds

N. Merino[1,2], I. Mateos[1,2], A. Díaz[1,2], C. Saro[1,2], S. López[1,2], M. J. Ranilla[1,2]
[1] Universidad de León, Campus de Vegazana, s/n, 24071 León, Spain, [2] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, 24346 Grullero, Spain

The integration of non-conventional feeds, such as agro-industrial by-products and discarded vegetables, into livestock diets is a key strategy for enhancing circularity in animal production. Including agro-industrial by-products in farm animal diets could reduce the costs of feeding and the environmental impact of their disposal. This study aimed to evaluate the in vitro gas rumen fermentation kinetics of seven feedstuffs: four conventional ingredients used in dairy sheep diets (corn, barley, soybean meal, and beet pulp) and four non-conventional feeds (discarded leek, bell pepper, and carrot). Samples (300 mg DM of each substrate) were incubated in batch cultures with diluted ruminal fluid at 39ºC during 144 h in 120 mL serum bottles (n=4). Gas production was measured at different times (3, 6, 9, 12, 17, 22, 26, 31, 36, 48, 72, 96, 120 and 144 h) for determination of gas production kinetics. Endogenous gas production was corrected by subtracting the gas volume produced by the corresponding blanks from the total gas produced in the vials. Data were fitted to a nonlinear model to estimate potential gas production (A), fractional rate (c) and lag time. Average gas production rate (AGPR) was also calculated. Gas production values were fitted to the model: Gas = A(1-e-c(t – Lag)), using the NLIN procedure of Statistical Analysis System (SAS). After 144 h, the residue was dried at 60ºC to calculate the effective degradability of the diet (DMED). Significant differences were observed among substrates for all parameters ($P<0.05$). Regarding asymptotic gas production, corn (95.87 mL/g DM), beet pulp (95.31 mL/g DM), and carrot (92.30 mL/g DM) showed the highest values, while soybean meal and leek presented the lowest (71.06 and 71.46 mL/g DM, respectively; $P<0.05$). The fractional fermentation rate and average gas production rate were significantly higher for carrot (0.066 %/h; 3.35 mL/h) and bell pepper (0.067 %/h; 3.07 mL/h) compared to conventional grains and beet pulp. Notably, corn exhibited the longest Lag time (9.23 h), whereas bell pepper showed the fastest initiation of fermentation (2.27 h). For DMED, carrot (45.85 %) and bell pepper (45.76 %) outperformed all other ingredients ($P<0.05$), including soybean meal (41.25 %) and conventional energy sources like barley (33.85 %) and corn (30.19 %). This study indicates that certain agro-industrial by-products, particularly carrots and bell peppers, appear to outperform traditional ingredients in fermentation rate and dry matter degradability. These findings would suggest that vegetable discards could serve as a sustainable substitute for costly energy sources like corn and barley, potentially enhancing the cost-effectiveness of ruminant production systems, provided further studies confirm these trends. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Assessment of gas production kinetics in dairy sheep diets including bell pepper as an ingredient replacing conventional feedstuffs

I. Mateos[1,2], N. Merino[1,2], A. Díaz[1,2], C. Saro[1,2], S. López[1,2], M. J. Ranilla[1,2]
[1] Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, [2] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, 24346 Grulleros, Spain

Spain is the leading bell pepper producer in the European Union, with an annual output exceeding 1.8 million tons. This massive production is coupled with a powerful food processing industry that generates significant quantities of surplus and cull products. Within a circular economy framework, upcycling these bell pepper residues as livestock feed offers a sustainable strategy to mitigate environmental impact while reducing feeding costs for ruminants. Therefore, the aim of this study was to evaluate the inclusion of discarded bell peppers in increasing proportions in a dairy sheep diet. Four different diets (a control diet (CON), and 3 diets with different proportions of bell pepper at 8% (PEP8), 16% (PEP16) and 24% (PEP24) replacing part of the concentrate ingredients) were evaluated. Three hundred mg of each diet were incubated at 39 ºC during 144 h in 120 mL serum bottles (n=4). The gas pressure was measured at different times (3, 6, 9, 12, 17, 22, 26, 31, 36, 48, 72, 96, 120 and 144 h). At the end of the incubation, the residue was dried in an oven at 60ºC to calculate the effective degradability of the diet (DMED). Data were fitted to a nonlinear model to estimate potential gas production, fractional rate and lag time. Average gas production rate was also calculated. Gas production values were fitted to the model: $Gas = A(1-e^{-c(t-Lag)})$, using the NLIN procedure of Statistical Analysis System (SAS). The Lag time decreased linearly (P>0.05) with increasing level of pepper (4.63, 3.25, 2.20, 2.41 h for CON, PEP8, PEP16 and PEP 24, respectively). The asymptotic gas production was similar (P>0.05) for the 4 diets (72.7, 73.8, 73.8 and 73.1 mL/g for CON, PEP8, PEP16 and PEP 24, respectively). The fractional rate of gas production was different (P<0.05) between diets (0.054, 0.049, 0.046 and 0.055 %/h for CON, PEP8, PEP16 and PEP 24, respectively) being higher for CON and PEP24 diets. In relation to the average gas production rate, there was a linear increase (P<0.05) when the proportion of pepper augmented in the rations (2.07, 2.10, 2.11, 2.43 mL/h for CON, PEP8, PEP16 and PEP 24, respectively). The DMED increased linearly (P<0.05) with increasing percentage of bell pepper in the ration (32.9, 33.3, 34.6, 36.9 % for CON, PEP8, PEP16 and PEP 24, respectively). Our results demonstrate that replacing concentrate with bell pepper, particularly at the 24 % DM inclusion level, significantly accelerates the onset of fermentation and linearly increases both the average gas production rate and the effective degradability of the diet. This enhancement in ruminal efficiency suggests that bell pepper residues can potentially substitute traditional energy sources in ruminant rations. However, given the high moisture content of this by-product and the presence of bioactive compounds, further in vitro and in vivo trials are necessary to evaluate long-term effects on ruminal fermentation, animal intake, milk yield, and metabolic health. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Gas production kinetics of dairy sheep diets with increasing amounts of leek

A. Díaz[1,2], I. Mateos[1,2], C. Saro[1,2], N. Merino[1,2], V. Rodríguez[1,2], M. J. Ranilla[1,2]
[1] Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, [2] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, 24346 Grulleros, Spain

The region of León has many vegetable processing industries that generate a big quantity of discarded product and wastes, posing a considerable environmental challenge if not properly managed. Leek, a traditional crop in Spain, is one of the most processed vegetables in the region. Furthermore, it contains organosulfur compounds that have been reported to modulate rumen fermentation. As they are underutilized for livestock nutrition, upcycling these vegetable wastes in ruminant diets could be an option to reduce the environmental impact of agroindustry. The objective of this study was to evaluate the effect of the inclusion of different proportions of leeks in a dairy sheep diet on rumen fermentation kinetics. Four diets (a control diet (CON), and 3 diets with different proportions of leek 8% (LEE8), 16% (LEE16) and 24% (LEE24) replacing part of the concentrate ingredients) were evaluated. Three hundred mg of each diet were incubated with diluted rumen fluid at 39 ºC for 144 h in 120 mL serum bottles (n=4). The gas pressure was measured at different times (3, 6, 9, 12, 17, 22, 26, 31, 36, 48, 72, 96, 120 and 144 h). After 144 h the residue was dried in an oven at 60º C to calculate the effective degradability of the diet (DMED). Endogenous gas production was corrected by subtracting the gas volume produced by the corresponding blanks from the total gas produced in the bottles. Data were fitted to a nonlinear model to estimate potential gas production, fractional rate and lag time. Average gas production rate was also calculated. Gas production values were fitted to the model: $Gas = A(1-e^{-c(t - Lag)})$, using the NLIN procedure of Statistical Analysis System (SAS). The Lag time decreased linearly ($P>0.05$) with increasing level of leek (4.63, 3.83, 3.08, 3.11 h for CON, LEE8, LEE16 and LEE 24, respectively). The asymptotic gas production (72.7, 70.3, 72.9 and 72.1 mL/g for CON, LEE8, LEE16 and LEE 24, respectively) and the fractional rate of gas production (0.054, 0.056, 0.053 and 0.056 %/h for CON, LEE8, LEE16 and LEE 24, respectively) were similar ($P>0.05$) in the four diets. There was a linear increase ($P<0.05$) in the average gas production rate when the proportion of leek increased in the diet (2.07, 2.15, 2.22, 2.30 mL/h for CON, LEE8, LEE16 and LEE 24, respectively). Similarly, the DMED increased linearly ($P<0.05$) with increasing percentage of leek in the diet (32.9, 33.0, 34.2, 35.1 % for CON, LEE8, LEE16 and LEE 24, respectively). Our findings indicate that including up to 24% of leek in the diet, replacing conventional feeds, optimizes the onset of in vitro fermentation and nutrient utilization, supporting the development of more sustainable and cost-effective feeding systems in the region. However, further research, including in vivo trials and assessments of milk quality and animal health, is required to confirm these results and determine the long-term effects of leek's organosulfur compounds on animal performance. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Effect of replacing corn with cull carrots in the diet of dairy sheep on milk retinol and tocopherols

J. Mateo[1], M. Valdés[1], D. Plata[1], I. Caro[3], A. Díaz[1,2], N. Merino[1,2], I. Mateos[1,2], F. J. Giráldez[2], C. Saro[1,2], M. J. Ranilla[1,2]

[1] Universidad de León, Campus de Vegazana, s/n, 24071 León, Spain, [2] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, 24346 Grulleros, Spain, [3] 3Universidad de Valladolid, Avda. Ramón y Cajal, 7, 47005 Valladolid, Spain

There is a growing trend toward incorporating agro-industrial by-products, such as cull vegetables, into ruminant livestock diets to boost farm sustainability and support circular economy initiatives. Cull vegetables can also contain high levels of specific nutrients or bioactive compounds that may improve animal health or can be transferred to the resulting food products. However, the influence of these alternatives on the final product must be scrutinized. This research investigated how including fresh chopped cull carrots in the diet of dairy sheep affects the levels of retinol and tocopherols in the milk of dairy ewes. Two groups of ten lactating Assaf ewes on the second third of lactation were fed on two different isoproteic and isoenergetic diets (total mixed rations) for 28 days. The control group received a total mixed ration ad libitum and the other received the same ration, but corn was totally replaced by fresh cull carrots (160 g/kg DM) previously chopped in 1 cm pieces. Milk yield was recorded daily, and milk samples were taken on the last day of the experiment to analyze retinol and tocopherols. The method utilized was based on reversed-phase high performance liquid chromatography following KOH saponification. During saponification, ascorbic acid and a nitrogen purge were employed to prevent oxidation. Vitamins were recovered in hexane and redissolved in methanol. The mobile phase consisted of methanol, with detection performed via photodiode array for retinol and fluorescence for tocopherols. Data were analyzed using an analysis of variance (ANOVA) to evaluate the impact of dietary treatment on vitamin concentration. The group supplemented with cull carrots exhibited significantly higher retinol levels (exceeding 30%; $P < 0.001$). Regarding tocopherols, while alpha-tocopherol concentration was unaffected by dietary treatment, gamma-tocopherol content was approximately two-fold higher in the control group ($P < 0.001$). Notably, gamma-tocopherol concentrations remained more than ten times lower than those of alpha-tocopherol. Overall, these findings suggest a nutritional advantage for milk produced by ewes fed cull carrots. Funding from the Spanish State Research Agency (AEI) and the European Regional Development Fund (Project PID2021-124648OB-C22) is gratefully acknowledged. N. Merino acknowledges the support of the Junta de Castilla y León for her predoctoral contract.

Chemical composition, fermentative characteristics and microbial quality of wet brewers' grains ensiled with dried citrus pulp or almond hulls

A. Alcamí-Aguado[1], J. M. Arroyo[1], T. De Evan[1], A. Recalde[1], J. L. Lema-Hurtado[1], C. Fernández[2], M. D. Carro[1]
[1] Universidad Politécnica de Madrid, Producción Agraria, Av. Puerta de Hierro 2, Moncloa-Aravaca, 28040 Madrid, Spain, [2] Universitat Politècnica de València, Instituto de Ciencia y Tecnología Animal, Camí de Vera, s/n, Edificio 7G, Algirós, 46022 Valencia, Spain

Wet brewers' grains (BG) are a valuable feed resource for ruminants due to their high protein and fiber content, but their high moisture content makes them prone to rapid spoilage and limits their practical use. Therefore, preservation techniques are needed, and ensiling is a promising option. However, the elevated moisture and low sugar content of BG pose challenges for effective silage preservation, but BG could be mixed with other raw materials for improving ensiling capacity. The aim of this study was to assess the chemical composition, fermentation end products and microbiological quality of wet BG ensiled with either dried citrus pulp (CPBG) or almond hulls (AHBG). Four silages of each treatment were prepared in vacuum bags (500 g mixture/bag) to reach about 37% dry matter (DM) in the mixture before ensiling and bags were stored for 90 days. Silages were opened and representative samples of their content were taken for measuring pH, concentrations of volatile fatty acids, NH3-N and lactic acid, and microbial quality. Data were analyzed by ANOVA with the type of silage as a fixed factor using the emmeans library of R software. The DM content pre-ensiling was 38.3 and 36.9% for AHBG and CPBG mixtures, respectively. At opening all silages exhibited good odor and coloration, with no visible mold growth or effluent formation. The CPBG silages had greater ($P<0.05$) DM losses than AHBG silages (8.70 vs. 5.32%) and lower ($P<0.05$) DM content (34.9 vs. 37.0%, respectively). The CPBG silages had lower ($P<0.05$) ash (5.04 vs. 6.77%; all results on DM basis), crude protein (16.5 vs. 17.4%), neutral detergent fiber (46.9 vs. 60.1%), acid detergent fiber (19.8 vs. 33.5%) and lignin content (4.78 vs. 14.6%), but greater water-soluble sugars content (8.43 vs. 2.05%; $P<0.001$) than AHBG silages, whereas there were no differences in ether extract levels (7.52 vs. 8.10% for CPBG and AHBG, respectively; $P=0.217$). The pH was lower ($P<0.05$) in CPBG than in AHBG (3.63 and 3.87, respectively), but all silages had pH values below the recommended value of 4.0. There were no differences between silages in the concentrations of lactic acid (49.3 and 54.7 g/kg DM for CPBG and AHBG, respectively; $P=0.100$) and acetic acid (3.28 g/kg DM for both silages; $P=0.981$), resulting in similar lactic/acetic ratios in both silages (15.1 and 16.7 for CPBG and AHBG, respectively; $P=0.207$). In contrast, NH3-N concentrations were greater in AHBG than in CPBG (6.48 vs. 0.31 g/kg DM) likely reflecting a greater CP degradation during storage in AHBG silages. Propionic acid was undetected in all silages and concentrations of butyric acid were low (average 0.058 and 0.574 g/kg DM for AHBG and CPBG silages, respectively), which are indicative of good fermentation. In agreement with these results, no presence of Clostridium perfringens, Escherichia coli, Listeria monocytogenes, Salmonella spp., Staphylococcus coagulase+ or molds were detected in any silage. The AHBG silages had greater ($P<0.001$) counts of Enterobacteriaceae spp. than the CPBG silages (3.60 vs. 2.53 log colony forming units (CFU)/g), but yeasts counts were similar (5.75 vs. 5.68 log CFU/g), being all values below the maximum recommended levels. The results suggest that both mixtures have good ensiling capacity and satisfactory microbial quality, although CPBG silages had greater DM losses during ensiling.

Variation in the composition of oil hemp (Cannabis sativa) and camelina (Camelina sativa) seeds

M. Lamminen[1], A. Halmemies-Beauchet-Filleau[1], T. Kokkonen[1]
[1] University of Helsinki, Department of Agricultural Sciences, P.O. Box 28, FI-00014 University of Helsinki, Finland

Camelina and oil hemp are promising oil and protein crops, which are valued due to their drought-resistance, low input requirements and potential to substitute conventional protein feeds such as rapeseed and soy in animal diets. However, little is known about the variation of composition of camelina and oil hemp seeds, which can influence both the efficiency of oil extraction and nutritive value of residual camelina and hemp cake and meal. The objective of the study was to collect information about the variation in the nutritive value of camelina and oil hemp seeds between different years and growing locations in Finland. Seed samples (n = 59 for oil hemp and n = 15 for camelina) were collected from batches farmers provided for Finnish companies TransFarm Oy and Suomen Kasviöljyt Oy during 2021-2024. For hemp, samples were taken from batches with low (<400 kg/ha, n= 27) and high yield (>600 kg/ha, n= 32). The 1000 seed weight (SW) of camelina (only 2021 samples, n=5) and hemp (only 2021-2022 samples, n=40) were determined, and all samples were analysed for dry matter (DM), ash, crude protein (CP), total fat, ash-free neutral detergent fibre (NDF), phytate phosphorus (P), and condensed tannins (CT). In addition, glucosinolates (9-methylsulfinylnonyl, 10-methylsulfinyldecyl and 11-methylsulfinylundecyl glucosinolate) were analysed from camelina seeds. The impact of yield on composition of hemp seed was analysed with two sample t-test using TTest and Mixed procedure of SAS. In addition, the Spearman correlation coefficients of 1000 SW with the composition of hemp seeds was analysed with Corr procedure of SAS. The hypothesis was that variation in the composition of camelina and hemp seeds exists, and the yield and SW of hemp influence seed composition, as the ratio of seed surface area to volume changes when the seed size changes. The 1000 SW of camelina was on average 1.24 g (min 1.08, max 1.38 g) and that of hemp 11.8 g (min 10.6, max 13.1 g). The average DM, ash, CP, total fat, and NDF concentration of hemp seeds were 931, 55.1, 260, 332 and 334 g/kg DM, respectively, and that of camelina seeds 920, 39.6, 284, 371 and 146 g/kg DM, respectively. The variation of fat concentration in camelina (min 250, max 413 g/kg DM) and hemp seeds (min 248, max 392 g/kg DM) was high, a difference which can result in around 3 times higher oil yield between maximum and minimum fat concentration seeds if extracted to residual fat concentration of 200 g/kg DM. Phytate P concentration of camelina seeds averaged 0.500 g/100 g DM and that of hemp seeds 0.896 g/100 g DM. The concentration of condensed tannins averaged 3.81 and 1.07 g/kg defatted seed mass on camelina and hemp, respectively. Total glucosinolate concentration of camelina seeds averaged 19.4 mmol/kg DM (min 12.9, max 27.6 mmol/kg DM) and was on 67% of samples below the maximum limit of 20 mmol/kg DM allowed for 00-varieties of rapeseed in animal nutrition. 1000 SW of hemp seed tended to be positively correlated with CP concentration (P=0.081, r=0.279), indicating the potential impact of seed yield on feed quality. No other impacts of yield on or correlation of 1000 SW with hemp seed composition were observed. In conclusion, this study demonstrated a variation in seed composition of camelina and oil hemp, with relevance to both oil extraction efficiency and nutritive value of residual cake or meal. The lack of precise hemp seed yield measurements and the use of categorial yield data (<400 kg/ha vs. >600 kg/ha) provided by the farmers reduced the sensitivity of the analysis and limited our ability to detect subtle relationships between yield and seed composition.

In vitro assessment of Sicilian agro-industrial by-products and derived biochars as potential feed ingredient for animal nutrition

C. Spedale[1], V. Chiofalo[1], M. Puglia[2], S. Pedrazzi[2], S. Frazzini[3], L. Rossi[3], M. Dell'Anno[1]
[1] University of Messina, Dep. of Veterinary Sciences, Polo Universitario Annunziata, 98168 Messina, Italy, [2] University of Modena and Reggio Emilia, Dep. of Engineering "Enzo Ferrari", Via P. Vivarelli, 41125 Modena, Italy, [3] University of Milan, Dep. of Veterinary Medicine and Animal Sciences, Via dell'Università, 26900 Lodi, Italy

In Sicily, agriculture plays a central economic role and generates substantial quantities of agro-industrial by-products from citrus fruits, olives, and pistachios food-chains, although partially reusable in livestock feeding, their high fibre content and variable composition may limit full nutritional exploitation. In this context, pyrolysis represents a sustainable valorisation strategy, enabling their transformation into biochar, an innovative, stable carbon-rich material with promising applications in animal nutrition, soil improvement, and environmental management. Recent studies suggest that biochar supplementation could be associated with improved health, nutrient utilization, reduction of greenhouse gas emissions, and microbiota modulation. This study aimed to comparatively evaluate the nutritional and functional properties of Sicilian agro-industrial by-products such as whole lemon pulp (WLP), depectinized lemon pulp (DLP), pistachio shells (PS), and olive kernel (OK) and to investigate the effects of pyrolysis on the bioactive profile of their corresponding biochars (WB, DB, PB, OB). Dried agro-industrial biomasses and their derived biochars, obtained by pyrolysis at 600°C for 60 minutes, were evaluated for bromatological composition following AOAC standard procedures. Antioxidant activity, polyphenols and flavonoids content were evaluated spectrophotometrically after solvent extraction of by-products and resulting biochars. Extracts were also tested for inhibitory activity against F18+ E. coli using a microdilution assay. Crude protein and ether extract were minimal across samples except for lemon by-products that showed higher residual content of these nutrients (CP 8.5%; EE 4.77% in DLP), PS exhibited the highest neutral detergent fiber content (92.41%), highlighting that the organic constitutes the largest component of these by-products; ashes represent the smallest component (PS: 0.35% and OK: 0.42%). OK displayed the highest antioxidant activity (1668.89 µmol Trolox eq/g ±66.69) and polyphenol content compared to other by-products ($p < 0.0001$). WLP showed the highest inhibitory activity against E. coli compared to the other samples ($p < 0.0001$), suggesting a residual presence of bioactive compounds. Biochar samples exhibited lower antioxidant activity (<10 µmol Trolox eq/g) compared with their respective raw biomasses, indicating the thermal degradation of phenolic compounds during pyrolysis. However, WB retained relatively higher antioxidant and inhibitory activity, reflecting properties of the original biomass. These findings highlight the promising potential of biochar derived from agro-industrial by-products for in vivo applications, suggesting that functional compounds are partially preserved even after the pyrolysis process. The key functional characteristic of biochar is the development of a highly porous structure during pyrolysis, which confers promising physicochemical properties and supports its potential in vivo applications, such as improving feed efficiency, modulating microbiota, promoting nutrient absorption, potentially adsorbing harmful compounds, and mitigating greenhouse gas emissions. The combination of biochar with fresh agro-industrial by-products could represent a promising strategy to valorise these residues within circular-economy frameworks, while supporting sustainable livestock nutrition and environmental mitigation.

The NUTRIFEEDS approach: Regenerative feed innovation through fermentation, insect bio-conversion and gut ecosystem modulation

J. Zentek[1], B. Martínez-Vallespín[1]
[1] Institute of Animal Nutrition, Faculty of Veterinary Medicine, Freie Universität Berlin, Königin-Luise-Str. 49, 14195 Berlin, Germany

This contribution presents the Horizon Europe project NUTRIFEEDS at its initial stage, outlining the scientific rationale, key hypotheses, and methodological framework that will guide forthcoming research. It also seeks to define the concept of "regenerative nutrition", which underpins a significant part of the project. By doing so, it introduces innovative research directions, fosters collaboration, and provides early insight into integrative approaches addressing key challenges in sustainable livestock production. Sustainable livestock production requires feeding strategies that enhance nutrient efficiency, gut health, and immune resilience while reducing environmental impact and reliance on imported protein sources. The Horizon Europe project NUTRIFEEDS (2025-2029) develops regenerative feed ingredients derived from drought- and heat-tolerant plants and agri-food side streams using targeted fermentation and Black Soldier Fly (Hermetia illucens) larvae bioconversion. Raw materials are comprehensively characterized, including nutrient composition and energy value, before undergoing targeted fermentation processes designed to reduce anti-nutritional factors, improve protein availability, and enrich bioactive metabolites. Insect-mediated bioconversion further increases nutrient density and may provide functional compounds with immunomodulatory properties. These technologies aim to transform underutilized regional biomass into high-value feed components within circular production systems. Experimental feeding trials in monogastric animals and ruminants evaluate effects on nutrient digestibility, intestinal morphology, barrier integrity, gut microbial composition, fermentation patterns, systemic immune markers, behaviour, and performance. Particular emphasis is placed on microbiome-host interactions and resilience under climate-related stressors. Multi-omics analyses are combined with AI-supported modelling approaches to identify mechanistic links between feed processing technologies, microbial ecosystem shifts, and host physiological responses. Beyond biological validation, the project integrates welfare indicators and farm-level sustainability metrics to assess practical applicability. By coupling biotechnology, animal nutrition, and data-driven modelling, NUTRIFEEDS seeks to establish science-based regenerative feeding strategies that enhance gut functionality, immune competence, and productivity while reducing environmental burdens. The project contributes to the development of circular, regionally adapted feed systems aligned with the EU Farm2Fork strategy and provides a framework for improving livestock resilience through targeted modulation of the gut ecosystem.

Rapid NIRS Evaluation of Cereal–Legume Forage Mixtures from Pre-Wilting to Ensiling

S. Currò[1], A. Latrofa[1], N. Guzzo[1], J. Bisello[1], S. Arango[1], V. Bondesan[2], L. Bailoni[1]
[1] University of Padova, Comparative Biomedicine and Fodd Science, viale dell'Università 16, 35020 Legnaro, Italy, [2] Veneto Agricoltura, Regional Agency for Agricolture, forestry and agrifood sectors, viale dell'Università 14, 35020 Legnaro, Italy

The increasing need for alternatives to conventional forage crops such as corn silage is particularly relevant in rainfed systems, where limited summer irrigation constrains livestock sustainability. Cereal-legume (CL) mixtures represent a strategic option for livestock systems, as they provide higher-protein forages, enhance on-farm feed self-sufficiency, and improve soil fertility through biological nitrogen fixation. However, the agronomic and nutritional performance of these mixtures is strongly influenced by species selection and mixture proportion, highlighting the need for accurate quality assessment. In this context, Near Infrared Spectroscopy (NIRS) offers a rapid, non-destructive, and cost-effective approach for predicting forage chemical composition and supporting feeding strategies. This study evaluated eight commercial forage mixtures differing in CL proportions: 100:0%, 50:50%, and 40:60%. The forages were sown in November 2024 at the Vallevecchia pilot farm (Veneto, Italy), harvested in May 2025, pre-wilted for 24 h, and ensiled in 14 L laboratory mini-silos for 60 days. At each stage (pre-wilted and silage), 32 samples (8 mixtures × 2 plots × 2 replicates) were analysed using official methods to determine dry matter (DM), ash, crude protein (CP), ether extract (EE), neutral detergent fibre (NDF), acid detergent fibre (ADF), net and gross acid detergent lignin (ADL), acid-insoluble ash (AIA), and starch. In addition, silage samples were evaluated for fermentation parameters, including pH, ammonia nitrogen, lactic, propionic, iso-butyric and n-butyric acids, and ethanol. Spectral data were acquired using a benchtop NIRS instrument (FOSS DS2500) in reflectance mode over the 850–2500 nm range. Separate calibration models were developed for pre-wilted and ensiled forages using modified partial least squares regression (WinISI software). Model performance was assessed by 5-fold cross-validation (cv), using the standard error (SEcv), coefficient of determination (R^2cv), and residual predictive deviation (RPDcv). Prediction performance was generally lower for pre-wilted than for silage samples. Good predictive performance was achieved only for ash and CP (R^2cv = 0.85 and 0.90; RPDcv = 2.54 and 3.10, respectively). Moderate performance was observed for gross ADL, starch, ADF, AIA, EE, and DM (R^2cv = 0.67–0.80; RPDcv = 1.72–2.26), whereas NDF and net ADL showed poor predictive performance (R^2cv < 0.66; RPDcv < 1.5). In contrast, ensiled samples exhibited markedly improved model performance. Excellent predictions (R^2cv > 0.91; RPDcv > 3.2) were obtained for DM, ash, CP, NDF, ADL, pH, and ethanol. Good predictive performance was achieved for AIA, starch, and major fermentation acids (lactic, propionic, and acetic acids), with R^2cv values between 0.82 and 0.90 and RPDcv ranging from 2.4 to 3.1. Conversely, iso- and n-butyric acids showed limited predictability (R^2cv = 0.65; RPDcv = 1.70), and EE was poorly predicted (R^2cv = 0.43; RPDcv = 1.31). Overall, NIRS proved to be a reliable tool for rapid characterization of CL mixtures, particularly at the ensiled stage. These findings highlight the potential of stage-specific calibration models to support efficient quality assessment and data-driven management of alternative forage and silage systems within sustainable livestock production. Effects of adaptation length to non-roughage finishing diets on intake, performance, and carcass traits of Bos indicus cattle

R. J. Oliveira[1], P. H. C. Ribeiro[1], L. M. Machado[1], E. B. Pereira[1], D. R. Oliveira[1], F. F. Alves[1], P. H. F. Torres[1], G. F. Virginio Junior[1], A. F. Toledo[1], D. D. Millen[1]

[1] São Paulo State University (UNESP), Animal Science, Via de Acesso Prof.Paulo Donato Castellane s/n, 14884-900 Jaboticabal, Brazil

Diets high in energy without any source of roughage have been increasingly adopted in intensive feedlot systems worldwide; however, adaptation strategies for cattle under these feeding conditions remain poorly defined, particularly regarding their effects on ruminal epithelial integrity and intake-driven performance. This study aimed to evaluate the effects of different adaptation lengths to non-roughage finishing diets on intake, performance, carcass traits, and ruminal morphometrics of Bos indicus cattle finished in a feedlot for 113 days. One hundred forty-four Nellore bulls (initial body weight [BW] 385.56 ± 7.4 kg) were blocked by BW, and randomly assigned to 1 of 36 pens (n = 4 per pen), according to the treatments: 1) Control: 14-day adaptation using a step-up protocol to a conventional finishing diet containing roughage sources; 2) 14-day restriction (R14): 14-day adaptation by quantitative restriction to a finishing diet with no roughage; and 3) 21-day restriction (R21): 21-day adaptation by quantitative restriction to a finishing diet with no roughage. Pens were treated as the experimental unit, with 12 replicates per treatment. Diets were formulated to be isoenergetic (1.29 Mcal kg^{-1} net energy for gain) and isonitrogenous. At harvest, rumens were individually scored for lesions, and a 1-cm^2 fragment of each rumen was collected from the cranial sac. The number of papillae per cm^2 of rumen wall (NOP) was determined, as well as the mean papillae area (MPA). The rumen wall absorptive surface area in cm^2 (ASA) was calculated as follows: 1 + (NOP*MPA) – (NOP*0.002). Data were analyzed using PROC MIXED of SAS, with treatment as a fixed effect and block as a random effect ($P < 0.05$). Control animals had greater final BW (566.8 vs. 519.4 and 517.8 kg; $P < 0.0001$), average daily gain (ADG; 1.56 vs. 1.18 and 1.17 kg; $P < 0.0001$), hot carcass weight (HCW; 314.4 vs. 293.2 and 284.9 kg; $P = 0.0007$), and daily dry matter intake (DMI; 9.67 vs. 7.65 and 7.46 kg; $P < 0.0001$) than cattle in R14 and R21, respectively. Rumenitis score was lower in control animals (1.89 vs. 7.16 and 7.40; $P < 0.0001$), but ruminal absorptive surface area was larger (24.97 vs. 20.0 and 19.84 cm^2; $P = 0.06$) than in cattle in R14 and R21, respectively. When all treatments were analyzed jointly, DMI was strongly associated with ADG ($r^2 = 0.739$; $P < 0.01$) and HCW ($r^2 = 0.533$; $P < 0.01$). Mixed model analysis confirmed a positive linear effect of DMI on ADG (≈ 0.15 kg increase per additional 1 kg DMI). Moreover, rumenitis score was negatively associated with DMI ($r^2 = 0.401$; $P < 0.01$). The negative association between the severity of rumen lesions and DMI implies that epithelial integrity was compromised and that voluntary DMI regulation was negatively affected. Thus, under non-roughage feeding, functional epithelial condition constrained performance by reducing DMI to cope with ruminal acidification. In conclusion, extending the adaptation period from 14 to 21 days did not improve DMI or performance on non-roughage finishing diets; thus, the original hypothesis was not supported. The DMI was the main driver of performance in this study, whereas ruminal lesion severity in cattle fed non-roughage diets limited DMI, resulting in a smaller ruminal absorptive surface area and impaired performance. Multi-property evaluation of late-gestation protein supplementation to improve reproductive efficiency in dry tropical beef systems

L. Prada E Silva[1], K. Mccosker[1], G. Somerset[1], K. Eyre[1]
[1] The University of Queensland, 306 Carmody Road, 4072 Brisbane, Australia

Reproductive efficiency in beef systems depends on the ability of cows to rear a viable calf and reconceive within the same production cycle. Population-scale monitoring of dry tropical herds has demonstrated substantial variability in performance, with low pregnancy rates within four months postpartum, particularly among first-lactation cows, and median fetal and calf losses approaching 10%. Nutritional and environmental constraints have been identified as major contributors to these losses. Late gestation therefore represents a critical window during which maternal nutrition may influence neonatal survival, subsequent fertility, and overall cow–calf productivity. The objective of this study was to test whether late-gestation protein supplementation reduces total calf loss and improves postpartum reconception under commercial dry tropical conditions. Pregnant heifers and multiparous cows (n = 6,570) were enrolled across 30 commercial herd-year units from 2022 to 2024 (8 properties in 2022, 12 in 2023, 10 in 2024). Within each property-year, cows were stratified by liveweight, calving date, and lactation status and randomly allocated to routine management (Control) or late-gestation supplementation (Supplemented). Supplemented cows received a protein- and energy-rich supplement for approximately six weeks before calving, formulated to supply 300–400 g crude protein/day, 9 MJ metabolisable energy, 16 g phosphorus, and 18 g calcium for a 500 kg cow. All supplements included 1.4% Saccharomyces cerevisiae fermentation products (NaturSafe®, Diamond V, USA). Outcomes included total calf loss (from confirmed pregnancy to weaning, including missing pregnant cows), reconception rate at weaning, and pregnancy within four months postpartum (P4M). Data were analysed using generalised linear mixed models with property and treatment × property fitted as random effects. Across 30 commercial herd-year units over three years, late-gestation supplementation improved reproductive outcomes compared with Control cows. Total calf loss was lower in Supplemented cows (13.3% vs 17.2%; P = 0.04). Missing pregnant cows (assumed mortality) were numerically lower in Supplemented cows (3.4% vs 5.1%) but were not significantly affected by treatment (P = 0.12). No treatment × year interactions were detected. Supplemented cows had higher reconception rates than Controls (77.7% vs 68.1%; P = 0.02) and tended to have a greater proportion pregnant within four months postpartum (64.5% vs 53.8%; P = 0.06). Reconception differed among age classes (P = 0.03), being higher in multiparous cows (85.7%) than in two-year-old heifers (77.4%) and yearlings (49.5%), and increased with pre-supplementation weight class (P = 0.02). Late-gestation protein supplementation reduced total calf loss and improved reconception while cows were lactating under commercial dry tropical conditions. The improvement in early postpartum pregnancy is consistent with enhanced periparturient metabolic and endocrine adaptation, potentially facilitating timely progesterone decline, colostrogenesis, and earlier resumption of ovarian cyclicity. These findings indicate that nutritional systems reliant on protein-deficient forages with minimal nitrogen supplementation may impose metabolic constraints during late gestation, thereby increasing reproductive losses. Targeted nutrient supply during this period appears necessary to mitigate biologically mediated constraints on reproductive efficiency in extensive beef systems.

Multi-Trait Growth Parameter Estimation in Beef Cattle Using a Bayesian Non-Likelihood Framework

M. M. Suma[1], M. Shirali[1,2], F. Lively[2], G. Pexas[3], I. Kyriazakis[1]
[1] Queen's University Belfast, School of Biological Sciences, IGFS, 19 Chlorine Gardens, BT9 5DL Belfast, United Kingdom, [2] Agri-Food and Bioscience Institute, Large Park, BT26 6DR Hillsborough, United Kingdom, [3] Cranfield Environment Centre, Cranfield University, MK43 0AL Bedford, United Kingdom

Predicting growth parameters using both Feed Intake (FI) and Live Weight (LW) data is essential for refining feeding strategies, enhancing genetic selection, and boosting overall herd productivity. To generate such information, traditional frequentist and Bayesian models, such as the Maximum Likelihood Estimation (MaxLik) and Bayesian Likelihood (BL) methods, often rely on rigid likelihood functions that may not effectively capture biological variability or the irregular data density typical of farm-scale records. This study examines the Approximate Bayesian Computation (ABC) framework as a more robust alternative for growth parameter estimation and for consistent predictive capacity under data-degradation scenarios, using the Gompertz growth model. The framework was developed using LW records from 476 Holstein cattle bred for beef production and was refined to 453 animals with concurrent FI and LW data, collected through historical research at the Agri-Food and Biosciences Institute (AFBI), Northern Ireland, via the Northern Ireland Farm Animal Biobank (NIFAB). Data were preprocessed to eliminate outliers and individuals with insufficient longitudinal records; FI was converted to Metabolizable Energy Intake (MEI). To evaluate the efficacy of ABC, a comparative analysis was conducted against the MaxLik and BL methods. Predictive accuracy was assessed using Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), and parameter coverage. Results for single-trait LW demonstrated that the ABC framework accurately recovered true growth parameters (growth rate $k \approx 0.11$month^{-1}; asymptotic weight $A \approx 1030$ kg) with a high predictive accuracy of MAPE = 3.5% and RMSE = 12 kg, representing a marginal 1.2% average deviation relative to the mature weight. By utilizing distance metrics rather than formal likelihoods, ABC achieved 99.3% empirical coverage rate for the 95% credible intervals compared to the BL approach (68.7%), offering a more reliable tool for characterizing growth trajectories. To evaluate performance under extreme scarcity, a data-degradation subset was created by reducing observations for animals with >11 records by 75%, leaving only 3–4 points per individual. In these sparse conditions, ABC yielded a lower RMSE (15 kg) than BL (16 kg), with MAPE increasing only marginally to 4.2% from 3.5% in the full dataset. Subsequently, MEI was integrated into a multi-trait ABC model, in which parameters were concurrently optimized to satisfy both traits. MEI parameters were estimated with an asymptotic intake $A2 \approx 6433$ MJ and a rate $k2 \approx 0.33$ month^{-1}. Under data degradation, the multi-trait ABC model remained stable, with MEI MAPE increasing only marginally to 24% from a 22% full-dataset baseline. While MEI RMSE values were 463 MJ and 443 MJ for sparse and full datasets, respectively, these represent a low relative error of approximately 7% of the asymptotic value, indicating high predictive stability despite the inherent volatility of intake data. Notably, ABC demonstrated superior reliability for MEI with 70.8% parameter coverage, significantly outperforming the BL approach (48.8%). These findings confirm that the ABC framework offers a robust computational method for identifying superior growth phenotypes. By maintaining high accuracy with minimal longitudinal records, this approach provides a logistically feasible solution for large-scale production settings where intensive data collection is often impractical.

Effects of adaptation protocols to non-forage high-energy diets on dry matter intake, rumen pH, and redox potential of cannulated Nellore cattle

B. C. Afonso[1], B. C. Petean[1], K. E. Loregian[1], A. F. Toledo[1], D. D. Millen[1]
[1] São Paulo State University – UNESP - School of Agricultural and Veterinary Sciences - Jaboticabal campus, Animal Science, Via Paulo Donato Castellane, S/N, 14884-900 Jaboticabal, Brazil

High-energy diets with reduced or absent forage inclusion have increased in beef cattle production systems, requiring appropriate adaptation protocols to maintain rumen health and feed efficiency. However, information regarding the metabolic responses of Nellore cattle to different adaptation protocols for non-forage high-energy diets remains limited. This study aimed to evaluate different nutritional protocols to adapt beef cattle to non-forage high-energy diets. Six cannulated Nellore cattle were enrolled in a duplicated 3 x 3 Latin square design to evaluate dry matter intake (DMI) and rumen parameters during adaptation and the entire feeding period. The experiment lasted 73 days, comprising three 21-day experimental periods with a 5-day washout interval between periods. Ruminal pH, temperature, and redox potential were continuously recorded every five minutes throughout each 21-day experimental period using a data logger. The trial was conducted, with the following treatments: 1) Control (CON): 14-day adaptation using a step-up protocol to a conventional finishing diet containing forage sources; 2) 14-day restriction (RES14): 14-day adaptation by quantitative restriction to a finishing diet with no forage; and 3) 21-day restriction (RES21): 21-day adaptation by quantitative restriction to a finishing diet with no forage. Diets were formulated on a dry matter basis using corn silage and concentrate ingredients, including non-forage fiber sources such as soybean hulls, citrus pulp, and cottonseed hulls. In the control protocol, corn silage was gradually reduced (45% to 25%) with a concomitant increase in concentrate. In the restriction protocols, cattle were fed a high-concentrate finishing diet without forage inclusion from day 1, starting at 1.2% of body weight and targeting 2.0% by the end of adaptation. Feed was offered once daily in the morning, and DMI was calculated as the difference between feed offered and refusals (DM basis). Data were analyzed using PROC MIXED (SAS, 2003), with means compared by Tukey's test. During the adaptation period, DMI, in kg/day and as % of body weight, was significantly greater in CON animals compared with those in RES14 and RES21 (10.26 vs. 7.27 and 6.42 kg, respectively; $P < 0.01$). Mean ruminal pH was reduced in cattle in RES21 compared with animals in CON and RES14 (6.11 vs. 6.52 and 6.48, respectively; $P = 0.04$), leading the rumen environment to stay longer under pH 6.2 for RES21 (922 vs. 336 and 609.55 min, respectively; $P = 0.01$). Redox potential was also affected by treatment, with a reduced value for RES14 (291 vs. 358 and 402 mV for CON and RES21, respectively; $P = 0.01$). Over the entire feeding period, DMI remained lower for cattle in RES14 and RES21 than for those in CON (7.39 and 6.42 vs. 10.31 kg, respectively; $P < 0.01$). Although mean ruminal pH was no longer different among treatments, cattle in RES14 spent more time below pH 5.2 than those in RES21 and CON (71.8 vs. 32.2 and 0, respectively; $P = 0.01$). The area under pH 6.2 also remained larger in the restricted groups (60.00 and 81.52 vs. 23.98 min; $P = 0.01$). Redox potential continued to differ among treatments, with greater values for CON and RES21 than RES14 (370.9 and 388.3 vs. 315.2 mV, respectively; $P = 0.03$). In conclusion, cattle adapting to non-forage high-concentrate diets decrease DMI as a result of ruminal acidification to avoid further variations in ruminal pH. Moreover, extending the adaptation restriction period from 14 to 21 days did not consistently improve ruminal stability.

Compositional and Nutritional Differences Among Major Forages in the Po Valley: A One-Year Analysis

M. Ottoboni[1], P. Premarajan[1], A. Luciano[1], M. Manoni[1], M. Senese[1], K. Simeonidis[1], A. Moradei[1], E. Pacifico[1], E. Grandi[2], L. Pinotti[1,3]

[1] University of Milan, Department of Veterinary Medicine and Animal Sciences, Via dell'università 6, 26900 Lodi, Italy, [2] Associazione Regionale Allevatori della Lombardia, Via Kennedy 30, 26013 Crema, Italy, [3] University of Milan, CRC I-WE, Via Trentacoste 2, 20134 Milano, Italy

Forage in the Po Valley is critical to the Northern Italian agricultural economy, providing the foundational feed for the region's intensive dairy sector, particularly for Protected Designation of Origin (PDO) cheeses like Parmigiano Reggiano (PR) and Grana Padano (GP). Dairy production for PR cheese mainly uses forages such as hays since silage is banned to prevent Clostridium contamination and potential swelling defects in the cheese with the lengthy seasoning period. While for fresh milk and GP cheese, maize silage is the mainstay forage base production. The system is characterized by high-input and high-yield, with about 80% of Italy's dairy cattle located here. However, this system faces significant challenges due to high nutritional variability in forage, driven by climatic extremes and management decisions. Accordingly, the present study aimed to evaluate the main compositional and nutritional differences in hay and silages analyzed in the Po Valley over the past year. The data analyzed in this work derive from the analyses carried out by the Regional Association of Livestock Breeders of Lombardy (ARAL) for farmers during the last crop season (11/2024-11/2025), that included 4250 feed samples, of which about 35% were silages and hays. Nutritional composition was determined by NIRs, while dry matter was determined by oven drying. One third of the samples studied for gross analysis were represented by maize silage; other samples analysed were, in descending order: earlage, grass silage, mixed meadow hay, sorghum forage silage, wheat forage silage, and alfalfa hay. To provide a general overview, two typical forages were considered, namely maize silage and mix meadow hay. As expected the nutritional composition of both maize silage and mix meadow hay were in line with mean values reported in literature. Considering variability within forage type, the most variable nutrient in maize silage was starch with a range of value between 10% and 47%. While in the case of mix meadow hay, the most variable nutrient was protein with a range of value between 4% and 18%. In conclusion, the present study confirmed the extend of nutritional variability in the main forage crop varieties used for dairy nutrition in the Po Valley (Italy). Thus, it is essential to monitor the feed nutritional values for precise nutrition. As a future perspective, long-term nutritional studies are recommended to evaluate the impact of climatic factors on nutrient composition, potentially enabling the prediction of nutrient variability over time.

Can entire male pigs be fatter by switching the sire line from Pietrain to Duroc or increasing dietary energy?

N. Quiniou[1], M. Monziols[1]
[1] IFIP, 9 Bd du Trieux, 35740 Pacé, France

Until recently, processing companies were able to select carcasses with a suitable fatness for dry-curing ham process. However, when most pigs produced on commercial farms originate from lean sire lines such as Piétrain and when the proportion of entire male pigs increases, this sorting strategy is reaching its limits. The aim of the study was to determine whether selecting a fatter crossbreed or increasing dietary energy level could modify growth performance and carcass characteristics in entire male pigs. Two successive batches were studied, providing nine blocks of four pens (six to seven pigs per pen). Pens were assigned to four treatments according to a 2 × 2 factorial design combining two commercial crossbreeds (progeny of Large White × Landrace sows inseminated with Piétrain NN or Duroc semen, referred to as xPP and xDU, respectively) and two dietary energy levels. Control diets C were formulated at 9.4 MJ net energy (NE)/kg, whereas the high-energy diets (H) were formulated at 10.0 MJ NE/kg, remaining within recommended levels to avoid boar taint. Pigs were fed ad libitum and slaughtered at 96 kg carcass weight. Growth rate, feed intake, feed efficiency were characterized on the farm and carcass characteristics were determined in a commercial slaughterhouse using the Image Meater grading method (2 batches) and with a computerised tomography (CT) scanner (1 batch). No consistent crossbreed × diet interactions were detected. Over the 26 to 123 kg body weight range, the avergae daily gain averaged 1070 g/d, without any significant effect of the sire line (P=0.27) or energy level (P=0.55). The high-energy diet improved feed conversion ratio expressed in kg/kg body weight gain (H: 2.21 vs C: 2.34; P=0.005), but not in MJ NE/kg (H: 24.25 vs C: 23.57; P=0.11). It slightly increased average backfat thickness over the vertebral bodies a, b, c, and d (G4, H: 22.8 vs C: 21.2 mm, P<0.001), without affecting the minimum fat thickness on the gluteus medius muscle (G3, H: 14.2 vs C: 13.5 mm; P=0.20). Switching to xDU increased NE intake per kg (xDU: 22.4 vs xPP: 21.9 MJ/kg; P=0.006) and fat thicknesses (G4: xDU: 22.7 vs xPP: 21.3 mm and G3: xDU: 14.7 vs xPP: 12.9 mm; P<0.001). It reduced carcass leanness assessed by Image Meater (xDU: 59.9 vs xPP: 61.3%; P<0.001) or CT scan (xDU: +4.3 pct unit; P<0.001). In ascending order, G4 values were obtained for xPP pigs fed diet C, xDU pigs fed diet C, xPP pigs fed diet H, and xDU pigs fed diet H, averaging 20.4, 21.9, 22.1 and 23.4 mm, respectively. Under ad libitum conditions, carcass fatness was more responsive to crossbreeding strategy than to dietary energy level.

Impact of increased dietary phytase levels during gestating sows on offspring performance, bone mineral content and mechanical properties

J. Suppi[1], E. Llauradó-Calero[1], M. Fornós[1], D. Solà-Oriol[1]
[1] Animal Nutrition and Welfare Service (SNiBA), Department of Animal and Food Science, Autonomus University of Barcelona (UAB), Travessera dels Turons, 08193 Bellaterra, Cerdanyola del Vallès, Spain

Proper skeletal development in piglets depends on sufficient maternal mineral supply during gestation. We hypothesized that increasing mineral availability in gestating sows through higher phytase supplementation would enhance placental mineral transfer and improve bone quality in newborn piglets. Therefore, this study evaluated the effects of increasing phytase levels from 300 FTU/kg to 1500 FTU/kg feed in gestating sows on offspring bone quality. A total of 60 sows (parity 0-8, equally distributed to treatments) were allocated to three dietary treatments based on phytase supplementation: Control (0 FTU group), commercial phytase level (300 FTU group), and high phytase level (1500 FTU group). Diets were provided from day 35 of gestation until farrowing. Offspring were individually weighed at birth, and mortality was recorded. One representative piglet per litter was euthanized at birth for bone sampling. Tibial mechanical properties were assessed using three-point bending, and the concentrations of Ca, P, Cu, Mn, and Zn were determined from tibial ash Performance data were analysed using a linear model. Tibial mechanical and mineral variables were using a generalized linear model with a gamma distribution and log transformation. Correlations were evaluated using Pearson's correlation coefficients. Phytase supplementation, regardless of inclusion level, had no effect on litter size (18–21 piglets per sow), total litter weight (24–27 kg), or average piglet birth weight (1.34–1.36 kg; $P > 0.05$). However, higher phytase supplementation tended to reduce litter variability, as reflected by a lower coefficient of variation, decreasing from 22–23% in the Control and 300 FTU groups to 18% in the 1500 FTU group ($P = 0.054$). In parallel, increasing phytase supplementation reduced the proportion of stillborn piglets in a dose-dependent manner, declining from nearly 17% in the 0 FTU group to about 10% at 300 FTU and 7% at 1500 FTU ($P < 0.001$). Regarding bone mineralization, tibial ash percentage did not differ among groups ($P = 0.415$), but both phosphorus and calcium concentrations increased linearly with increasing phytase levels ($P < 0.001$). Regarding the mechanical properties, although maximum compressive stress was higher in piglets from the 300 FTU group compared to Control ($P = 0.040$), no further differences were detected among treatments ($P > 0.05$). Correlation analyses revealed that Ca and P concentrations were positively associated with bone density ($r = 0.36$, $P = 0.017$; $r = 0.32$, $P = 0.033$, respectively). However, Ca was negatively correlated with bones' stiffness (Young's modulus; $r = -0.31$, $P = 0.043$) and tended to be negatively associated with proof resilience ($r = -0.27$, $P = 0.075$). Manganese concentration was negatively correlated with cortical area ($r = -0.44$, $P = 0.0027$) and second moment of inertia ($r = -0.39$, $P = 0.0087$) but positively associated with maximum compressive stress ($r = 0.35$, $P = 0.021$) and maximum tensile stress ($r = 0.31$, $P = 0.040$). In conclusion, high dosing phytase during gestation increased foetal tibial mineral deposition and reduced within-litter variability and stillbirth rate, without affecting overall sow or litter growth performance. However, enhanced mineral content did not consistently improve mechanical properties of the tibia, underscoring that skeletal resilience depends not only on mineral concentration but also on bone geometry and matrix quality.

Molecular mechanism and nutrition regulation of meat quality traits in Chinese Indigenous Pigs

Y. Duan[1], Y. Yin[1]
[1] Institute of Subtropical Agriculture, Chinese Academy of Sciences, No. 644 Yuanda Road, Furong District, Changsha Hunan 410125, China, 410125 Changsha, China

This study aims to investigate the mechanisms underlying the superior meat quality traits of Chinese local pig breeds and to establish corresponding precision nutrition regulation techniques. First, six Shaziling (S) and Yorkshire (Y) pigs at 30, 60, 90, 150, 210, and 300 d of age were selected to examine carcass traits and meat quality, in order to find the critical window for meat quality in S pigs. Our results showed that the body weight, carcass length, and loin eye area of S pigs at 150, 210, and 300 d of age were significantly lower than those of Y pigs ($P < 0.05$). S pigs at 150 and 300 d of ages had significantly lower backfat thickness than Y pigs ($P < 0.05$). Compared with Y pigs, S pigs at all 6 ages had lower lean percentage and higher fat percentage ($P < 0.05$), respectively. At 60, 90, and 150 d of age, the post-mortem pH-decline, b* value (yellowness), and drip loss of S pigs were significantly lower than those of Y pigs ($P < 0.05$). Moreover, at 150 d of age, S pigs had significantly higher a* value (redness) and intramuscular fat (IMF) content than Y pigs ($P < 0.05$). In conclusion, S pigs have a slower growth rate but better meat quality than Y pigs. The meat quality of S pigs is the best at 150 to 210 d of age. Then, to identify the top ranked metabolite enriched in metabolic pathways for the S pig meat flavor, we evaluated the composition of amino acids, fatty acids, and metabolic profiles in the longissimus thoracis muscle (LM) of S pigs aged 30, 90, 150, 210, and 300 days. Results showed that glutamate (Glu) is the top ranked metabolite enriched in metabolic pathways for the S pig meat flavor. Moreover, the muscular Glu concentration is positively correlated with total essential amino acids, flavor amino acids, and sweet amino acids of S pigs. Finally, during the critical window period for the formation of meat quality traits, we used Glu to feed S pigs in order to improve their meat quality. Our results indicated that Glu could simultaneously increase the lean percentage and IMF content and decrease the fat percentage of Shaziling pigs, and these beneficial effects may be related to increased colonic Spirochaetota abundance and acetic acid concentrations.

How deviations of requirement feed intake during mid gestation affects sows' body composition

R. Carnevale[1,2,3], S. Millet[1,3], N. Nollet[4], C. Garbossa[2], A. Cools[1,4], G. Janssens[1]
[1] Ghent University, , Heidestraat 19, 9820 Merelbeke, Belgium, [2] University of São Paulo, Brazil, Av. Duque de Caxias Norte, 255, 13635-900 Pirassununga, Brazil, [3] Flanders Research Institute for Agriculture, Fisheries and Food, Burg. van Gansberghelaan 119, 9820 Melle, Belgium, [4] Inagro, Ieperseweg 87, 8800 Rumbeke-Beitem, Belgium

Feeding during early gestation typically focuses on restoring body reserves, while late gestation diets must provide increased nutrient intake to support fetal growth. During mid-gestation, nutrient requirements are assumed to be mainly for maintenance. Therefore, gestational feeding strategies, such as "high–low–high" schemes, are often used in practice. Despite their practical use, the effects of moderate deviations from recommended energy intake during mid-gestation on sow fat and muscle reserves remain unclear. This study aimed to evaluate the effects of feeding sows at 25% below, at, or 25% above estimated metabolic requirements during mid gestation (day 35-85) on backfat thickness and loin depth dynamics throughout gestation and until weaning. A total of 111 sows from seven batches (parity 1–8) were included. During early gestation (days 0–34), all sows were fed amounts calculated based on their metabolic requirements (Dourmad et al., 2017). From mid to late gestation (day 35 – 85), feeding varied by experimental group: LESS (n=38) sows were fed 25% less than calculated requirements; REQ (n=37) sows fed at requirement; and EXTRA (n=36) sows were fed at 25% above requirement. From day 85 until farrowing all sows were fed at requirement. Backfat thickness and loin depth at the P2 point were measured by B-mode ultrasound on days 0, 35, 70, 85, and 105. The number of mummies, born alive and stillborn piglets was recorded. Data were analyzed with mixed linear models including the parity and batch as random effects and for the sows body composition parameters the backfat at day 35m the sow and the interaction of time and treatment were also included (lmer, R). Backfat thickness was affected by treatment ($P = 0.005$), time ($P < 0.001$), and their interaction ($P < 0.001$). No differences were observed among treatments at the beginning of gestation. From day 85 onward, REQ and EXTRA animals exhibited greater backfat thickness compared with LESS. Backfat declined toward weaning in all groups, with no differences detected at that timepoint. Loin depth was affected by time ($P < 0.001$), but not by treatment ($P = 0.33$) or the treatment × time interaction ($P = 0.14$). Values increased from early gestation to mid-gestation and declined toward weaning across all groups. No differences were detected among nutritional treatments for litter size, number of mummies, or stillborn piglets ($P = 0.94$), litter weight at birth or at weaning ($P = 0.94$). Mid- to late-gestation feed restriction reduced backfat deposition, while the similar backfat values in REQ and EXTRA groups suggest that providing feed above requirements did not result in further fat deposition and the excess energy may have been redirected. The absence of treatment effects at weaning indicates compensatory mobilization of body reserves during late gestation and/or lactation. In contrast, loin depth was unaffected by nutritional level, indicating that moderate deviations (±25%) from requirements during mid-gestation influence fat deposition rather than muscle development. These findings suggest a higher sensitivity of body fat, than muscle reserves, to gestational feeding level and emphasize the importance of meeting nutrient requirements to maintain adequate sow body condition.

His supplementation increases muscle carnosine concentrations in weaned piglets.

A. J. Galindo[1,2], D. Solà-Oriol[2], M. Paniagua[1]
[1] Quimidroga SA, Technical Department, Tuset 26, 08006 Barcelona, Spain, [2] Universitat Autònoma de Barcelona, Department of Animal and Food Science, SNiBA, Travessera dels Turons, 08193 Bellaterra, Spain

Histidine (His) is an essential amino acid in swine that participates in multiple metabolic processes beyond growth performance. It serves as a precursor of histamine, involved in digestion and inflammatory responses, and it is part of the heme group of hemoglobin, essential for oxygen transport. His is also a component of serine proteases, the pancreatic enzymes responsible for protein digestion in the small intestine. Additionally, His is part of the histidine-containing dipeptides, being carnosine (Car) one of the most important. Principally present in skeletal muscle, Car is composed of L-His and β-alanine, serving as an antioxidant, pH buffer, metal chelator and His reservoir. It has been suggested that His requirements may not be fully reflected by growth performance alone, but also by muscle Car reserves. Therefore, this study aimed to evaluate the effects of His supplementation on muscle carnosine content and growth performance of weaned piglets over time. Ten mixed-sex nursery pigs [(Landrace x Yorkshire) × Pietrain] with an initial BW of 6.18± 0.36kg and 25 days of age were allotted to two dietary treatments (n= 5) differing in the SID His:Lys ratio (32% vs 38%) for 42 days. A two-phase diet was applied with a 16% crude protein during phase 1 (0-15 days) and 18% during phase 2 (15-42 days). All pigs were individually weighed on days 0, 7, 15, 28 and 42 of the trial. During phase 1, blood samples were collected to determine free His concentrations. On days 0, 15 and 42, a sample of Longissimus dorsi (LD) of each pig was collected through needle biopsy, allowing the individual monitoring of muscle Car content throughout the study. Statistical analysis was performed using R software. Data were analyzed with mixed models as repeated measures including treatment, time and their interaction as fixed effects and individual as random. At the end of phase 1, no significant differences were detected in BW (7.67 vs. 8.26kg; P=0.262), serum free His (9.20 vs. 12.27µg/mL; P= 0.578), or muscle Car concentrations (195.5 vs.197.9mg Car/100 g muscle; P=0.956). Although BW showed numerical differences on day 42 (18.16 vs. 20.26 kg), this effect was not significant (P=0.305), likely due to the limited sample size. Finally, pigs fed His supplemented diets showed increased Car concentrations in the LD on day 42 (161 vs. 306 mg Car/100 g muscle; P<0.05). His requirements should consider muscle Car concentration due to its role as His donor, and it is concluded that piglets fed His supplemented diets showed greater Car concentration in skeletal muscle.

Acorns from intensive holm oak plantations during Montanera finishing phase: impact on the fatty acid and antioxidant profiles of Iberian pig meat

A. Ortiz[1], J. García-Gudiño[1], M. Freire[1], L. León[1], J. M. Pérez-Rodríguez[1], A. I. Del Rosario[1], D. Tejerina[1]
[1] Centre of Scientific and Technological Research of Extremadura, Meat Quality and Animal Production Area, Ctra, A-V, Km372, 06187 Guadajira, Spain

Climate change is intensifying interannual fluctuations in natural acorn availability during the Montanera finishing phase, increasingly challenging the ability of some Iberian pigs to reach the minimum weight gain requirements established by Spanish quality standards, leading to economic losses for farmers due to animal disqualification. As a climate adaptation strategy to avoid these losses while enhancing the resilience of this traditional Iberian pig production system and preserving product quality, supplementation with acorns from intensively managed and irrigated holm oak plantations may provide a viable solution. This study aimed to evaluate the impact of this supplementation during the final Montanera phase of pure Iberian pigs on the fatty acid and antioxidant profiles. A total of 85 purebred Iberian Retinto pigs started the Montanera finishing phase under traditional conditions. After 48 days, 10 pigs with insufficient growth and 10 pigs showing adequate performance were selected. The underperforming group was supplemented with 10 kg/day of acorns from intensively managed and irrigated holm oak plantations established in 2018 using grafted plants on seedling rootstock, located in the "La Orden" Agricultural Research Center (CICYTEX) (southwestern Spain), while the control group continued under traditional Montanera conditions. Both groups completed the same 63-day finishing period consuming acorns of comparable nutritional composition. After slaughter, longissimus thoracis et lumborum (LTL) muscles were removed from the carcasses; one was subjected to a dry-curing process for 70 days under standard industrial conditions, while the other was analyzed fresh. Then, intramuscular fat was extracted for analysis of tocopherols (α- and γ-tocopherol) by HPLC and fatty acid profile by GC-FID. Results showed that, in fresh loin, acorn supplementation from intensive holm oak plantations resulted in similar α- and γ-tocopherol contents compared to traditional Montanera. No significant differences were observed in the fatty acid profile, including major fatty acids and the proportions of saturated, monounsaturated and polyunsaturated fatty acids. Likewise, in dry-cured loin, tocopherol contents and fatty acid composition were largely unaffected by supplementation, apart from a significantly lower C18:3 n-3 content in the acorn-supplemented group ($P < 0.05$). These results demonstrate that supplementation with acorns from intensive holm oak plantations preserve the distinctive fatty acid and antioxidant profiles characteristic of traditional Montanera finishing and therefore may be considered as strategy to enhance the resilience of Montanera traditional production system. Effects of Dietary Extruded Flaxseed and Betaine on Haematological and Biochemical Parameters in Finishing Pigs

D. Outor-Monteiro[1,2], S. Mendes[3], T. Santos[4], J. Páie-Ribeiro[1,2], V. Pinheiro[1,2]
[1] UTAD, Zootecnia, Quinta de Prados, 5000-801 Vila Real, Portugal, [2] CECAV / AL4Als, Quinta de Prados, 5000-801 Vila Real, Portugal, [3] REAGRO, Av. da República 35 1º,, 1050-186 Lisboa, Portugal, [4] DON CASEL, Av. Gonçalo Rodrigues Caldeira 25, 6100-711 Sertã, Portugal

Abstract: The use of functional feed ingredients in pig production has increased due to their potential to improve animal health and meat quality. Flaxseed (Linum usitatissimum) is a rich source of omega-3 fatty acids, particularly α-linolenic acid, and its dietary inclusion has been associated with anti-inflammatory effects, modulation of lipid metabolism and improvements in meat fatty acid profile. Betaine plays important roles in performance, carcass traits and stress resilience, potentially supporting better efficiency in pigs. Therefore, the incorporation of flaxseed and betaine in pig diets may represent a nutritional strategy to enhance both animal performance and may affect blood biochemical and haematological indicators reflecting animal health and metabolic responses. The aim of this study was to evaluate the effects of dietary extruded flaxseed supplementation, with or without betaine, on haematological and biochemical parameters in finishing pigs. The study was conducted using forty female pigs ((LW x LR) x DU) monitored during 43 days in the finishing phase, between approximately 94 and 137 kg body weight. Animals were allocated to four dietary treatments in four pens each with ten animals: control diet (T1), diet supplemented with extruded flaxseed level 1 (T2), diet supplemented with extruded flaxseed level 2 (T3), and diet supplemented with extruded flaxseed level 1 plus betaine (T4). Blood samples were collected and analysed to evaluate biochemical and haematological parameters. Data were analyzed using a variance test with feed as the variance factor and Tukey test were used for multiple comparison of means. The JMP pro 17 program was used for statistical analysis. Among the biochemical variables analysed, lactate dehydrogenase (LDH) was significantly affected by dietary treatments ($p = 0.023$). The highest values were observed in pigs receiving T4 (713 U/L), which were statistically similar to T2 (552 U/L), while T3 (482 U/L) and T1 (472 U/L) presented the lowest values. Alkaline phosphatase showed a tendency towards significance ($p = 0.054$), with higher values in pigs receiving T2 (120.60 U/L) and T4 (119.10 U/L), while animals fed the control diet (T1) presented the lowest values (96.21 U/L), like T3 (101.56 U/L). Total cholesterol also showed a tendency towards significance ($p = 0.057$). The highest values were observed in pigs receiving T1 (90.99 mg/dL) and T4 (89.56 mg/dL), whereas T2 showed the lowest values (81.22 mg/dL), followed by T3 (88.72 mg/dL). These variations may reflect metabolic effects related to lipid metabolism modulation promoted by dietary fatty acids. No significant differences were observed among treatments for the remaining haematological parameters evaluated ($p > 0.05$). These results suggest that dietary supplementation with extruded flaxseed, particularly when combined with betaine, may influence specific biochemical markers associated with metabolic activity in finishing pigs, although the general haematological profile remained stable across treatments. Keywords: Pig metabolism, haematology, flaxseed, betaine

Effects of harvest time, dry matter content and additives on fermentation characteristics of grass-clover silage

J. Perez[1], J. Dicksved[1], M. Presto Åkerfeldt[2], H. Gonda[1]
[1] Swedish University of Agricultural Sciences, Department of Applied Animal Science and Welfare, Box 7024, 750 07 Uppsala, Sweden, [2] Uppsala University, Department of Research and Collaboration Support, Box 256, 751 05 Uppsala, Sweden

Silage from ley crops has potential as a locally produced feed resource for pig farming, providing nutrients while decreasing reliance on more expensive protein feeds and supporting natural behaviours that enhance animal welfare. However, the nutritional quality depends on various factors, including the grass-to-legume ratio, which often varies between cuts, and the dry matter (DM) content at ensiling. This lab-scale study aimed to investigate how the grass-to-legume ratio, DM content of the ensiled herbage, and the type of additive used at ensiling influence the chemical composition of the silage intended for pig feeding. A laboratory-scale silage trial was conducted to assess the effects of harvest time, DM content and additives at ensiling, on the fermentation characteristics of grass-clover silage for pigs. A grass-legume ley, composed of perennial ryegrass (Lolium perenne) and white clover (Trifolium repens), was harvested on two occasions (1st and 2nd cuts) and ensiled with two DM contents (low, LDM; and high, HDM), and treated with no additive (CONT), a propionic-formic acid mix (ACID), or a lactic acid bacteria (Lactobacillus paracasei, L. plantarum, L. brevis) inoculant (INOC). Sixty vacuum-sealed mini-silos were prepared and analysed after three months for pH, chemical composition, ammonia-N, and fermentation products. Fermentation was influenced by the cut, DM level, additives, and their interactions. Bacterial inoculation at low DM produced silage with intense fermentation, lower pH, and higher lactic and acetic acid production. Acid treatment resulted in less intense fermentation, higher WSC content, and the lowest ammonia-N content compared to the INOC and CONT treatments. Butyric acid remained low across all treatments, except in HDM 2nd cut CONT. Overall, ACID-treated silages showed improved stability, with reduced proteolysis, making them more suitable for pig feeding. These findings suggest that combining an appropriate DM content with acid treatment of grass-legume ley could enhance silage quality, functioning as a protein source and improving feed utilisation in organic pig production scenarios.

Short-term protein-energy restriction in starter diets triggers compensatory growth, increased ghrelin and improved jejunal morphology in weanling pigs

M. A. C. George Kalaivanan[1], S. Cho[1]
[1] Dankook University, Department Of Animal Biotechnology, Dandae-Ro, Dongnam-Gu, Cheonan-Si, Chungcheongnam-Do, 31116 Cheonan, South Korea

Nutrient supply during the immediate post-weaning period shapes both the growth trajectory and the endocrine signals that govern appetite and efficiency. In this study, we evaluated whether the nutritional restriction through a low-protein and low-energy (LP-LE) starter diet induces early growth depression but permits compensatory responses after pigs return to a balanced diet. A total of 80 [Landrace ×Yorkshire] × Duroc) weaning pigs with an average initial body weight of 6.34 ±1.15 kg were randomly assigned to 2 dietary groups with 10 replications of 4 pigs/pen for 6 weeks. Diets were fed in two phases: CON: balanced diet in phase 1 (week 0-3) and phase 2 (week 3-6); TRT: compensatory diet (LP-LE diet) in phase 1 and the balanced diet in phase 2. Growth performance [body weight (BW), average daily gain (ADG), average daily feed intake (ADFI), and gain to feed ratio (G: F)] was recorded by period (week 0-3, 3-6) and overall. Blood was collected at week 3 and 6 for appetite-related hormones, including ghrelin. Jejunal morphology (villus height, crypt depth, and villus: crypt ratio) was assessed at the end of Phase1 and 2. In addition, taste and nutrient-sensing gene expression in tongue tissue was evaluated at week 6 by qRT-PCR. All data were analysed with GLM procedure of SAS using pen as the experimental unit. $P< 0.05$ was considered as statistically significant. During the phase 1, pigs fed LP-LE diet showed significantly lower BW (13.57 vs 14.01 kg; P=0.049), ADG (347 vs 365 g/d; P=0.041) and G:F (0.675 vs 0.807; P=0.0046), but higher ADFI (517 vs 457 g/d; P=0.024) compared with CON, confirming immediate growth depression under LP-LE diet. After phase 2, ADG, ADFI, and G:F did not differ between treatments, and final BW at week 6 was similar (25.74 vs 25.96 kg; P=0.626) , indicating a recovery in growth range during the later period. Serum ghrelin at week 3 was significantly higher in TRT than CON, whereas no difference was observed at week 6. It could suggest an appetite-stimulating endocrine response to nutrient restriction, potentially facilitating subsequent compensation upon re-feeding. TRT increased villus height (459.30 vs 438.67 µm; P=0.046) and villus:crypt ratio (1.94 vs 1.76; P=0.010) while reducing crypt depth (237.04 vs 249.57 µm; P=0.049), suggesting mucosal adaptation following restriction and re-feeding. At qRT-PCR, FFAR4 of the tongue tissue showed lower expression in TRT, while no clear differences were observed in glucose transporters (SGLT1, GLUT2) or umami taste receptor genes (T1R1, T1R2, T1R3), indicating that the molecular memory of early-life restriction may be specifically linked to long-chain fatty acid signalling. Collectively, a 3-week LP–LE starter strategy transiently impairs early growth and efficiency but permits full recovery by 6-week once pigs resume a balanced diet. The concurrent rise in ghrelin and improved jejunal morphology may suggest endocrine and mucosal adaptations that may support compensatory growth. The significant down-regulation of FFAR4 serves as a molecular signature of the compensatory growth process, likely reflecting an adaptive shift in lipid-sensing sensitivity following the transition to a high-energy diet. This approach may offer flexibility for cost-sensitive starter formulations, provided that pigs are subsequently re-fed with a nutritionally adequate diet. The future study should quantify long-term carcass outcomes, integrate additional metabolic and satiety hormones and growth factors for intestinal villi to describe causal pathways. KEYWORDS: Compensatory growth, weaning pigs, ghrelin, intestinal morphology, gene expression.

Optimizing early and mid-gestation feed allowance improves litter outcomes in sows under summer heat stress

J. H. Lee[1], S. M. Koo[1], S. N. Jo[1], J. C. Jang[1]
[1] Gyeongsang National University, 1Division of Animal Science, 501, Jinju-daero, Jinju-si, Gyeongsangnam-do, 52828 Jinju, South Korea

Summer heat stress can reduces voluntary feed intake while increases maintenance energy requirements, potentially impairing energy balance in gestating sows and subsequent piglet growth. As nutrient demands change throughout gestation, the optimal timing of increas feed allowance under hot conditions remains unclear. This study investigated how increasing feed allowance during early and/or mid-gestation affects sow body weight (BW), piglet growth, inflammatory responses, stress indices, gut permeability, and fecal microbiota. Fourty crossbred gestating sows (Landrace × Yorkshire) were assigned to four treatments (n = 10 per treatment) in a 2 × 2 factorial design based on early-gestation (Control [C]: 2.3 kg/d; High [H]: 3.0 kg/d) and mid-gestation (C: 2.0 kg/d; H: 2.7 kg/d) feeding levels. Treatments were defined as H–H, H–C, C–H, and C–C. All sows received the same feed allowance (3.0 kg/d) during late gestation. Sow BW and backfat thickness were measured on d 0, 30, 75, and 110. Postweaning, serum cytokines, hair cortisol, gut permeability markers, and targeted fecal bacteria were analyzed.. Sow BW was highest in H-H and lowest in C-C at d (185.2 vs 166.4 kg; $P < 0.05$) and d 110 (199.4 vs 177.3 kg; $P < 0.01$), whereas backfat thickness and total born did not differ ($P > 0.10$). . However, stillbirths tended to be higher in H-H than C-C ($P = 0.06$). Piglet birth weight was highest in C-H ($P < 0.01$), and litter weaning weight was greatest in C-C (72.9 vs 61.4–65.9 kg; $P = 0.03$), despite individual weaning weights and weaning-to-estrus intervals being similar ($P > 0.10$). Physiological markers (cytokines, cortisol, gut permeability, andmicrobiota did not differ among treatments. In conclusion, while persistently elevated feeding (H-H) during summer increased sow BW, it tended to increase stillbirths. Conversely, stage-specific fine-tuning (such as C-H for optimal birth weight or C-C for litter weaning weight) improved reproductive outcomes without altering physiological stress markers.

Effects of Extruded Linseed and Betaine on Growth Performance of Finishing Pigs

D. Outor-Monteiro[1,2], S. Mendes[3], T. Santos[4], J. Páie-Ribeiro[1,2], V. Pinheiro[1,2]
[1] UTAD, Zootecnia, Quinta de prados, 5000-801 Vila Real, Portugal, [2] CECAV Al4Als, Quinta de Prados, 5000-801 Vila Real, Portugal, [3] REAGRO, Av. da República 35 1º,, 1050-186 Lisboa, Portugal, [4] DON Casel, Av. da República 35 1º, 1050-186 Lisboa, 6100-711 Sertã, Portugal

Dietary strategies aimed at improving pork nutritional quality have gained increasing attention in recent years. Flaxseed (Linum usitatissimum) is rich in omega-3 fatty acids, particularly α-linolenic acid, and its inclusion in pig diets has been associated with improvements in meat fatty-acid profile and potential benefits for animal performance. In addition, betaine plays important roles in performance, carcass traits and stress resilience, potentially supporting better efficiency in pigs. Therefore, the incorporation of flaxseed and betaine in pig diets may represent a nutritional strategy to enhance both animal performance and heat stress resilience. This study aimed to evaluate the effect of dietary supplementation with extruded flaxseed, with or without betain, on the growth performance of finishing pigs. Forty female pigs ((LW x LR) x DU) were monitored for 43 days during the finishing phase, from approximately 94 to 137 kg body weight. Animals were allocated to four dietary treatments in four pens each with ten animals: control diet (T1); diet supplemented with extruded flaxseed at level 1 (T2); diet supplemented with extruded flaxseed at level 2 (T3); and diet supplemented with extruded flaxseed at level 1 plus betaine (T4). Body weight and feed intake were monitored individually throughout the experimental period in automatic feeding stations (NEDAP Pig Performance Tester). Data were analyzed using a variance test with feed as the variance factor and Tukey test were used for multiple comparison of means. The JMP pro 17 program was used for statistical analysis. No significant differences were observed in initial or final body weight among treatments ($p > 0.05$). However, dietary treatments significantly affected total weight gain and average daily gain ($p = 0.001$). Pigs receiving T2 showed the highest weight gain during the trial (48.9 kg) and growth rate (1062 g/day), while T1 and T3 presented lower values (41.1 and 41.3 kg; 893 and 897 g/day, respectively). Animals fed T4 showed intermediate performance (42.3 kg; 919 g/day). Feed intake was not significantly affected by dietary treatments ($p > 0.05$). However, the animals in group T4 showed a higher consumption than the other groups (2967, 3139, 3057, 3233g/day, for T1, T2, T3, T4, respectively). Feed conversion ratio was significantly improved in pigs receiving T2 (2.96) compared with T3 (3.46) and T4 (3.52), while T1 showed intermediate values (3.33) ($p = 0.0016$). These results suggest that dietary supplementation with extruded flaxseed may influence growth performance in finishing pigs, particularly when included at appropriate levels, highlighting its potential as a nutritional strategy in pig production systems. Keywords: Finishing pigs, growth performances, flaxseed, betaine

The devil is in the details: Is longevity a good indicator of farm animal welfare?

M. A. Von Keyserlingk[1], S. E. Bolton[1], K. L. Proudfoot[2]
[1] The University of British Columbia, Animal Welfare Program, 2357 Main Mall, V6T 1Z6 Vancouver, Canada,
[2] University of Prince Edward Island, Atlantic Veterinary College, 550 University Avenue, C1A 4P3 Charlottetown, Canada

Animal welfare is a complex, multi-faceted concept, making farm animal assessments extremely challenging. Different actors place varying levels of importance on the different constructs of animal welfare, with these priorities often dictated by their personal values. Animal care practices are also commonly conceptualized through a sustainability lens, ideally placing equal importance on economic viability, social acceptability, and environmental impact. Not surprisingly, given the importance of economic viability, many animal welfare assessments give primary focus to whether an animal is in good health and productive. In contrast, questions about how the animal feels (e.g., absence of pain), and whether the animal is able live according to its nature (e.g., perform natural behaviours that are thought to be important to it, such as grazing) receive much less attention in on-farm animal welfare assessments. Within the discussions surrounding farm animal welfare and sustainability, the issue of longevity has been introduced as a possible indicator of animal welfare. Longevity in humans is defined by the Merriam-Webster dictionary as pertaining to the length of life, and as such, has been used as a key indicator when assessing quality of life and well-being. This indicator is arguably well positioned to assess human well-being given the associations between long life, good health, and happiness. However, the adoption of longevity as an indicator of welfare in farm animals is less straightforward. The length of a farm animal's life is more likely to depend on key economic drivers, rather than the animal's quality of life. In this presentation we will discuss why the term 'longevity' must not be treated as a one-dimensional concept. Rather, increasing the length of a farm animal's life presents potential advantages and disadvantages when it comes to animal welfare and sustainability more broadly. For example, within the dairy cattle literature, longevity has often been argued to be a key indicator of welfare, yet involuntary culling – the killing of animals that are sick or injured – can lead to improved animal welfare by reducing suffering and shortening length of life. In contrast, given that dairy cattle are a significant contributor to the meat supply, we argue that the slaughter of a healthy younger animal would likely be more accepted by society than keeping the animal alive longer when risks to welfare are high, such as during long-duration transportation. Moreover, there is a growing body of evidence that the public does not expect that farm animals live a long life but rather that their life, however short, has meaning and purpose, including through their contribution to the food supply.

Genetics meets management: Explaining the gap between genetic and phenotypic trends of longevity in dairy cattle

L. Hüneke[1], G. Thaller[2], C. Schmidtmann[1]
[1] IT-Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany, [2] Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany

Longevity is one of the key traits in dairy cattle breeding, as it directly influences herd structure and replacement rates and thereby contributes to overall production efficiency. In addition to its economic relevance, longevity has gained attention in societal and political discussions, where it is often perceived as an indicator of animal welfare. Between 2010 and 2024, considerable genetic progress in longevity was achieved, with an average annual increase of 24.4 days. In contrast, the corresponding phenotypic trend exhibited a substantially lower rate of increase, amounting to only 9.6 additional days per year in the same period.To investigate the discrepancy between genetic improvement and phenotypic trends, we performed comprehensive analyses using data from German Holstein cattle, encompassing disposal years 2010 to 2025. Several hypotheses were tested, considering external influences and management practices as potential explanatory factors for the observed trends.Our findings provide strong evidence that management practices constitute the principal determinants of phenotypic longevity. For instance, the milk price crisis in 2015/2016 had a strong negative impact on phenotypic longevity, as economic pressure prompted management decisions such as herd downsizing or prioritizing culling over treatment. Further stratified analysis by herd size revealed that larger herds generally exhibited shorter longevity compared to herds with fewer than 200 cows, indicating that structural and management-related factors linked to herd scale may substantially influence longevity of the cows.Another key factor identified was replacement and insemination management. The use of sexed semen and beef semen in dairy herds alters the availability of purebred female calves suitable for herd replacement. A greater supply of replacement animals increases selection intensity and may lead to earlier culling, thereby reducing phenotypic longevity independently of the animals' health status. This indicates that cows are frequently unable to fully express their genetic potential, as they are culled prematurely due to management-related decisions. Such practices contribute significantly to the observed discrepancy between the genetic and phenotypic trend.Overall, the results clearly demonstrate that various management factors play a dominant role in phenotypic longevity, while animal welfare and health seem to have a comparatively minor impact. Most culling decisions are driven by management and economics rather than health-related issues. Consequently, longevity should not be interpreted as a reliable proxy indicator of animal welfare.

Investigations on an optimal longevity of dairy cows in practical farms in the North-East of Germany

A. Römer[1], J. Harms[1], A. Boldt[1], P. Sanftleben[1]
[1] State Research Center of Agriculture and Fisheries Mecklenburg-Vorpommern, Institute of Livestock Farming, Wilhelm-Stahl-Allee 2, DE-18196 Dummerstorf, Germany

Aim of the analyses was to investigate when a cow should be culled because of her age. The question was whether cows that are too old slow down breeding progress to such an extent that it has negative consequences for the dairy farm's economy. Therefore, we used data of breeding organizations RinderAllianz and Rinderproduktion Berlin-Brandenburg with testherd information from 2024. Data included 68,251 German Holstein cows with 22,088 cullings. The influence of milk yield (305-ECM), lifetime performance, lifetime efficiency, health (every first veterinary treatment per diagnosis), and somatic cell count on contribution margin was analysed using a mixed linear model using SAS software (version 9.4, SAS Institute Inc.). Contribution margin was calculated including cost of heifers, male calves, feed, labour, veterinary treatments per diagnosis, labour efforts per diagnosis, inhibitor milk, variable rearing costs as well as milk revenues and revenues of culled cows and male calves. Results show, that a cow should be milked up to 7th lactation, from point of view of milk yield (breeding value included). There is no threshold responding lifetime efficiency. Health of dairy cows decreased with every lactation. Mastitis increased from first to 4th lactation by a factor of 2.4. Claw and leg disorders increased by a factor of 2.1 from first to 4th lactation. But very old cows (9th and more lactations) seemed to have a better claw health. Disorders of metabolism were 4 times higher in the 4th lactation compared to first lactating cows. Somatic cell count exceeded the limit of 400,000 cells/ml from the 4th lactation onwards. Genetically, young cows are the best. But cows that have grown old were once the best too. For somatic cell count cows up to 6th lactation had a breeding value above 100 points. The relative breeding value of milk yield fell below 100 points from the fourth lactation onwards (with an annual depreciation of 130 kg of milk). The relative breeding value of longevity was above 100 points until the fifth lactation (with an annual depreciation of 2.4 points). Cullings of first lactating cows decreased within last 8 years from 24 % of all culled cows within herds to only 14 % in 2024. Contribution margins per cow and lactation increased up to 8th and more lactations. No limit lactation number could be determined. More data with significantly older cows are necessary. With regard to the contribution margin no limit of age of dairy cows was calculated in this analyses. More cows with 8 and more lactations are necessary for further investigations. An optimal age composition of dairy herds should contain 20 % first lactating cows, 18 % of cows in second lactation, 16 % in 3rd, 14 % in 4th and a minimum of 5 % in 8th and more lactations. Older cows have a higher risk of illness. Therefore, prevention, hygiene, and early disease detection are essential. Another way to reduce critical phases of dairy cows' life is an extended lactation.

Mortality and lifetime milk yields of Finnish dairy cows during 2011 - 2020

K. Sarjokari[1,2], K. Hagner[3,4], H. Nordgren[4], T. Hurme[2], H. Rautala[1], P. Rajala-Schultz[1]
[1] Faculty of Veterinary Medicine, University of Helsinki, Department of Production Animal Medicine, Paroninkuja 20, 04920 Saarentaus, Finland, [2] Natural Resources Institute Finland (Luke), Tietotie 4, 31600 Jokioinen, Finland, [3] Finnish Food Authority, Production and Companion Animal Pathology Section, Mustialankatu 3, 00790 Helsinki, Finland, [4] Faculty of Veterinary Medicine, Department of veterinary Biosciences, BOX 66, 00014 Helsinki, Finland

Mortality among dairy cow herds includes animals that have died on farm, either unassisted or by euthanasia. High mortality indicates impaired animal welfare and represents wasted resources: 1) dead cows exit the food chain, 2) deaths are often preceded with work and other used resources, and 3) mortality may shorten herds´ productive lifespan and lead to raising more replacement heifers. Through those, mortality potentially influences carbon footprint of milk production. Mortality is affected by decisions of dairy farmers who adjust feeding, management and housing of their herds based on their own values and knowledge, expectations set by dairies and legislation, and fluctuating market prices of milk and meat. Because of these, sizes of dairy herds are increasing and housing changes from tie stall to free stall barns in many European countries. In some countries, including Finland, farmers also shift from conventional to automatic milking systems (AMS) and from other breeds to Holstein (HOL) cows. Along these changes, mortality of cows has increased. Despite that, only a handful of studies have analysed long-term trends in mortality, and none of them separated unassisted and euthanised deaths. Our aim was to gain more knowledge with which dairy cow mortality could be decreased in the future. We explored annual herd-level recordings of 3 179 Finnish dairy herds that were actively producing milk during 2011 to 2020, using descriptive statistics and generalized mixed-effects regression models. Of the studied herd-years, 83 % were with both Ayrshire and HOL cows in herd, and average milk yield of 9 064 kg in 2011 and 9 879 kg in 2020. In Finland, herds with less than 40 cows are mostly housed in tie stall barn, and herds with 40 or more cows in free stall barns. In our data, 41 % of 40 – 99 cow herds and 68 % of herds with 100 or more cows were milked with AMS. We observed a U-shaped trend in overall mortality (OM), which was due to changes in proportion of euthanised cows (EUT, between 4 to 5 %). Unassisted deaths (DIED) remained stable (at 2 %). As a result of changes in OM and a linear decrease in culling % (from 33 to 30 %), proportion of mortality of total culling (MTC) first decreased (from 19 % in 2011 to 18 % in 2013) and then increased, being 24 % in 2020. OM, EUT, DIED and MTC percentages were all at lower levels in herds with less than 40 cows and at higher level in herds with 100 or more cows, compared herds with 40 to 99 cows. However, within those three groups, no clear associations were observed between OM and number of cows in a herd. In contrast, EUT % increased linearly over time along the increase in HOL cows % in the herd, in all those herd size groups. Bigger herds had higher proportions of HOL cows (55 % in 100 or more cow herds; 46 % in 40 – 99 cow herds; 37 % in less than 40 cow herds). Average age at culling (AGE) increased by 8 months and lifetime milk yield (LMY) by 4 800 kg (from 25 129 to 29 893 kg) between 2011 and 2020. The association between AGE and HOL % was U-shaped, but LMY increased with proportion of HOL cows in herd. Our results suggest that observed differences in mortality between herds of various sizes are more probably reflections of many factors (like selection of breeds) than actual effects of number of cows.

Longitudinal evidence that genomic functional longevity reflects biological resilience in Holstein Friesian cows

M. Hosseini Ghaffari[1], N. Melzer[1], D. Wittenburg[1], M. Elsabagh[2], D. Becker[1], F. Becker[1], C. Kröger-Koch[1], H. M. Hammon[1]

[1] Research Institute for Farm Animal Biology, (FBN), ,, 18196 Dummerstorf, Germany, [2] University of Al Dhaid, ,, , Sharjah, United Arab Emirates

Extending functional longevity in high-producing dairy cows is essential for improving economic efficiency, environmental sustainability, and animal welfare in modern production systems. This longitudinal experimental study validated the biological expression of Genomic Functional Longevity Breeding Values (GFLBV) in a stratified cohort of Holstein Friesian F0 cows managed under uniform conditions for over a decade. Pregnant heifers were genomically classified into High-GFLBV (n = 18) and Low-GFLBV (n = 18) groups while being matched for Genomic Milk Production Breeding Values (GMPBV), thereby isolating survival-related genetic effects from production potential. Lifetime phenotypes, including milk yield, milk composition, reproductive performance, survival time, and detailed veterinary diagnoses, were recorded and analyzed using estimation-based statistics and Kaplan–Meier survival modeling. Milk production trajectories and energy-corrected yield were comparable between groups across parities, confirming successful decoupling of production intensity from longevity. Despite equivalent yield, Low-GFLBV cows exhibited consistently higher weighted disease burden beginning in lactation 1, initially characterized by severe mastitis clustering and transition-related disorders, progressing to multimorbidity dominated by infectious and mechanical claw lesions in lactation 2, and consolidating into a lameness–fertility constraint by lactation 3. Attrition accelerated markedly in Low-GFLBV cows from lactations 2–5, with complete cohort extinction by lactation 6, whereas High-GFLBV cows persisted into lactations 7–9. Survival analysis demonstrated sustained separation of hazard curves, confirming extended median survival in High-GFLBV cows. These findings provide rare long-term experimental evidence that genomic functional longevity captures intrinsic immunometabolic robustness and structural resilience independent of milk yield, supporting its integration into breeding programs targeting sustainable lifetime performance.

Sow longevity: phenotypic time trends, the effect of litter size, and economic values

P. Knap[1], J. Holl[2], C. Lewis[3]
[1] Genus-PIC, Lorbeerrosenweg 10, 30916 Isernhagen, Germany, [2] Genus-PIC, 100 Bluegrass Commons Bvd 2200, 37075 Hendersonville TN, United States, [3] Genus-PIC, C/Pau Vila 22-2, 08174 Sant Cugat del Valles, Spain

We analyzed data of 352,904 PIC-Camborough® parent sows housed in 322 commercial farms across the world. From sow birthyear 2000 to 2024, litter size (total number born, TNB) steadily increased each year by 0.16 piglets per litter. We performed a continuous-time survival analysis on these data, stratified by sow birthyear, adjusting for a random farm effect, with the average lifetime TNB per sow as a curvilinear covariate. From 2000 to 2023, the general sow survival rates decreased steadily with tentative signs of a turnaround since 2022. However, relative to the average TNB of 12.7 piglets per litter, the estimated hazard ratios (i.e. the probabilities of not surviving) for sows with lower or higher TNB decreased over time (i.e. their survival improved over time). We also performed a discrete-time survival analysis on these data, stratified by sow birthyear and adjusting for a random farm effect. This produced estimates of the conditional survival probabilities (CSP) per parity number per sow birthyear; these CSP estimates were used to derive the marginal economic values (MEVs) of TNB and of the sow survival rate up to parity 4 (S(p4)). Due to the upward time trend in TNB and the downward time trend in S(p4), the MEVs of these traits have gradually grown close together, so that their contributions to a profit-oriented breeding goal are becoming very similar. These data on Camborough sows show a similar overall reduction of sow longevity over time as is reported in the literature, but they hold no evidence for an important effect of increasing TNB levels in this process. In these data the optimum TNB level with respect to sow longevity has increased from just over 11 in sow birthyear 2000 to almost 17 in 2023.

Long-life sows: how breeding performance tailors longevity in breeding farms

A. Arrazola[1], R. Quintanilla[1], N. Alòs[1], L. Tusell[1], J. Tarrés[1]
[1] IRTA, Animal Breeding and Genetics, Torre Marimon, 08140 Caldes de Montbui, Spain

Elevated mortality and high removal rate of breeding sows is becoming a growing problem in the swine industry due to concerns about the management, physical health, and wellbeing of commercial sows. Thence, the objective of this study was to assess the survival curves of breeding sows and evaluate how breeding performance records impact their longevity in commercial conditions. Data from 557 Spanish breeding farms were extracted through the BDporc platform (www.bdporc.irta.es/en) retaining a total of 2,693,711 historical cycle records from 565,621 sows removed between 2022 and 2024 (both included). A COX model was developed at the sow level to estimate sows' probability to survive to the next breeding cycle based on lifetime, breeding parameters (age at first mating, average first-mating-to-conception interval, abortion incidence, average number of piglets born alive and weaned, and average weaning-to-breeding interval), season, and year as categorical factors and farm as a random effect. The overall survival probability of commercial sows decreased linearly from cycle one to five (50 % probability) and exponentially thereafter to less than 5% in cycle nine. Indeed, 16 % of sows did not reach their second breeding cycle. Besides the high variability across farms, breeding problems (infertility, anestrous, and abortions) and prolificity throughout their lifetime were common drivers of early sow removal and mortality. Sows with long weaning-to-breeding intervals (> 20 days) had 2.75 greater odds of removal than sows bred in less than a week after weaning. Also, sows that took more than three weeks to get pregnant had 88 % more chances of being removed than those that conceived in less than a week. To a lesser extent, the hazard ratio was significantly higher (1.16-1.17) for sows that have had a miscarriage throughout their lifetime than those that never had an abortion. In terms of prolificity, sows that farrowed and weaned more than 10 piglets per parity had the highest survival likelihood throughout their breeding career whilst those nurturing more than 20 piglets per litter had 84 % higher odds of removal before the next breeding cycle. Sow survival was also significantly influenced by age at first mating, season, and year. Altogether, these results highlight that breeding problems and low prolificity are priming factors of early removal and mortality in commercial sows. On the other side, farrowing and nurturing large litters (> 20 piglets per parity) can undermine the life expectancy of hyperprolific sows in commercial breeding barns. These results support the close link between sow breeding performance and longevity. Practically, efforts to prevent breeding problems may help reduce high early removal rate and mortality in breeding farms, and limiting litter size to 20 piglets per sow during lactation may also support the longevity of multiparous sows.

A multi model, multi imputation framework for predicting sow culling risk across parities

M. Sungirai[1], C. Mulvenna[1], R. Muns[1]
[1] Agri-Food and Biosciences Institute, Sustainable Livestock Systems, Large Park, BT26 6DR Hillsborough, United Kingdom

Sow culling and mortality are a health and economic challenge for pig producers. Traditional parametric lineal models to study and identify risk factors for sow culling are challenging due to limited sample sizes, high individual variability, biology shifts across parities and collinearity among recorded parameters. Hence, we studied the use of statistical learning models as a tool to identify risks factors for culling. We hypothesised that adding data from biomarkers obtained from saliva, colostrum and milk would enhance predictive accuracy of parity-specific culling risk models beyond what is achievable with traditional analysis using routinely collected production traits alone. We used data from 120 sows monitored longitudinally over up to five consecutive parities at our pig research unit. A two-phase modelling workflow was developed to evaluate our hypothesis. In the first phase, models incorporated only routine production traits, including body condition measures, feed intake traits, reproductive outputs and Δ values for body weight, body condition score and backfat, calculated as the difference between weaning and farrowing. All predictors were standardised, and missing data were imputed using ten-fold multivariate imputation by chained equations. Three modelling approaches: full logistic regression, stepwise AIC regression, and elastic net regression with cross-validation were fitted across all imputed datasets for each parity to characterise collinearity, establish a parsimonious baseline, and identify stable variable selection behaviour. In phase two, biomarker panels from saliva, colostrum and milk were added to the same base variables used in phase one. Biomarkers were categorised by sampling stage: peak of lactation (day 10 of lactation) and the day before weaning (day 27). Stability selection was applied to quantify the consistency with which each biomarker was selected across imputations and subsampling, producing both selection frequencies and empirical p-values. Model performance was compared using Area Under the Curve (AUC) between models created from phase one data and models created from phase two data. Routine traits alone produced moderate predictive ability with distinct parity-specific effects and high collinearity. Biomarkers combined with routine traits showed statistically significant improvements during early parities. The saliva biomarker panel produced the largest improvement in parity one, improving the AUC from 0.62 to 0.76 for a ΔAUC ~0.14, with extremely strong support from Fisher combined p values ~10^{-21}. The saliva biomarkers with the highest stability across parities were C-reactive protein and amylase at weaning, and advanced oxidation protein products and cortisol at peak lactation; all exceeding our threshold for stability (> 0.30). The colostrum biomarker panel showed similar predictive improvement (ΔAUC ~0.13). Milk biomarkers showed more modest improvements (ΔAUC ~0.076). By parity four, improvements were minimal across all biomarker panels, likely reflecting a physiological ceiling effect in which routine data already captures much of the decline associated with late parity culling risk. In conclusion, this two-phase, multi-model and multi-imputation framework provides a robust and biologically interpretable method for predicting sow culling risk. Elastic net regression emerges as the most reliable and stable modelling approach. Biomarker integration, particularly saliva biomarkers measured at weaning and peak lactation, substantially enhances prediction in early parities. These findings highlight the potential of biomarker-assisted risk assessment for precision management within commercial sow farms.

Extensification is not one-dimensional: contrasting welfare and meat quality responses to space, enrichment and roughage in fattening pigs

M. Coutant[1], M. S. Hedemann[1], M. S. Grønbeck[2], M. Hviid[2], L. J. Pedersen[1], M. L. V. Larsen[1]
[1] Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, [2] Danish Technological Institute, Danish Meat Research Institute, Gregersensvej 9, 2630 Taastrup, Denmark

Extensification strategies are increasingly promoted to improve pig welfare and align production with societal expectations and evolving legislation. However, the consequences of implementing extensification measures in otherwise intensive systems remain poorly understood across welfare and production outcomes. This work, conducted within the mEATquality project (European Union grant no. 101000344), assessed how three individual extensification measures (increased space allowance, point-source enrichment, and daily roughage provision) affect welfare, growth, and meat quality in finishing pigs under intensive conditions. Across two production batches, pigs were exposed to increased space allowances (1.4 m²/pig, n=108 or 2.1 m²/pig, n=72), point-source enrichment (ropes, paper bags, and wood logs, n=214), or roughage (2-5 kg per pen per day, n=215), and compared with a conventional control (0.7 m²/pig, n=215). Welfare outcomes included damaging behaviours, pen fouling, gastric ulcerations, feeder access, and night-time resting behaviour. Increasing space allowance reduced tail biting and ear biting (up to 88% fewer biting events in the treatment with the most space), and pen fouling (up to 90% fewer events, $p<0.05$). Increased space was also associated with improved access to the feeder (up to 75% fewer observations of blocked feeder headspaces in the week prior to slaughter) compared with the control ($p<0.01$). Increased space also influenced resting at night, with pigs given more space having a higher probability of lying on the solid floor and with limited body contact compared with the control ($p<0.01$). However, the treatment with the most space was also associated with a higher prevalence of gastric ulcerations (approximately 50% of the pigs, $p<0.05$), possibly due to a greater intake of highly concentrated feed, as reflected in a greater growth rate. In contrast, roughage provision reduced gastric ulcerations by 40% but was associated with increased ear biting and pen fouling, possibly due to increased competition when roughage was provided directly in a pile on the floor. Similarly, point enrichment did not prevent tail biting outbreaks and even exacerbated problems once an outbreak had developed, possibly due to increased competition around enrichment points. Overall, responses differed across welfare indicators, demonstrating that extensification measures do not uniformly improve welfare, as unintended negative effects occurred in certain contexts. Extensification factors had limited effects on meat quality traits. However, pigs showed approximately 5% increased growth and carcass weight in the treatment with the greatest space allowance compared with control and roughage treatments ($p<0.05$). Experimental batch significantly affected several meat quality and growth parameters ($p<0.01$), indicating that environmental and management variation had a stronger influence than extensification factors and/or that the tested strategies were too moderate to affect meat quality. Overall, the findings show that extensification measures influence welfare and production components in distinct and sometimes contrasting ways, highlighting trade-offs rather than uniform improvements. These results suggest that resilience in pigs is unlikely to be achieved through single housing or management modifications implemented in isolation; instead, extensification strategies should integrate improvements across multiple aspects, including housing, feeding, enrichment, and management, to support animal resilience.

Straw in, straw out: Do quantity and location of straw affect pig health in welfare label farms?

N. Nöllenburg[1], C. Winckler[1], S. Schwarz[1], C. Leeb[1]
[1] BOKU University, Department for Agricultural Sciences, Gregor-Mendel-Straße 33, 1180 Vienna, Austria

Welfare label farms are an emerging trend in Austria, which account for 5% of the pork production with a rising tendency. The most common label farm is characterized by a reduced stocking density (1.4m2/pig at 110kg), the use of straw, different floor types, functional areas and access to an outdoor area. All of these measures are known to improve pig welfare as they support natural behavior (e.g., foraging/lying) and can alleviate behavioral disorders (e.g., tail biting). Nevertheless, there is less evidence wether welfare systems have health benefits. Therefore, the aim of this study was to investigate the effect of straw location and quantity on health-related slaughter data. Over a period of one year, data of 23 welfare label farms in Austria were gathered. The farms were divided into two groups: 1) retrofit farms with a mostly fully slatted indoor area (feeding and elimination) but high straw provision (>50 g/day/animal) in the outdoor lying area (HighStraw_OUT; n=10) and 2) usually newly built farms with low straw provision indoors in the lying area (<50 g/day/animal) and a partially slatted outdoor area without straw for feeding and elimination (LowStraw_IN; n=13). Slaughter data in terms of pathological changes of lung (pneumonia), pleura (pleurisy) and heart (pericarditis) as well as adhesion of the pluck, abscesses and arthritis were collected by official veterinarians for each farm. A Wilcoxon rank-sum test was carried out for all six health parameters to test for differences between the farm types. The median prevalence of pneumonia was 25.6%, which is in line with other studies. HighStraw_OUT animals had significantly more pneumonia than LowStraw_IN pigs (median: 39% vs. 22.7%; p=0.021). The prevalence of all the other respiratory health related parameters did not differ between farm types and was generally low (median pleurisy: 10.3%; pericarditis: 2.2%; adhesion of the pluck: 1%). Arthritis which can be associated with an inadequate lying area (amongst other reasons) did not differ between farm types but was numerically lower in HighStraw_OUT (median: 0.2% vs. 0.4%; p=0.943). The prevalence of abscesses possibly caused by tail-biting or other systemic infections did also not differ between HighStraw_OUT and LowStraw_IN (median: 1.2% vs. 1.1%; p=0.724). It has to be underlined that these findings are preliminary and have to be interpreted with caution as they do not account for other abattoir-, farm- and pen-specific factors. However, they were collected across a whole year and for in total 35.577 pigs which provides a reasonable sample size. The prevalence of respiratory problems was higher compared to other studies. The higher prevalence of pneumonia in HighStraw_Out pigs could be explained by no clear separation of functional areas in this farm type, since pigs may use the slatted flooring indoors as well as the deep straw outdoors as elimination area. Hence, higher ammonia concentrations in the lying area could cause lung problems, even though the lying area is in the outdoor run with less dust exposure compared to the LowStraw_IN systems. Here, pigs lie indoors and do barely eliminate in that area. The lack of difference concerning arthritis and abcesses may be explained by the low prevalence in both systems and their multifactorial nature. These results suggest that there is a need to improve respiratory health across both welfare label systems. However, especially for HighStraw_OUT systems further investigations are necessary to identify influencing factors (e.g., ammonia emissions, ventilation, manure management). Based on this, improvement measures can be implemented on existing farms and should be considered when designing new ones.

Effects of farrowing in pens or crates on sows and piglets

A. Vernunft[1], C. Gladbach[1], H. Lickfett[1], M. Oster[1], K. Wimmers[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl Allee 2, 18196 Dummerstorf, Germany

Worldwide, farrowing in crates has become the standard practice. This achieves work efficiency but is also expected to protect the piglets, but it also raises animal welfare issues. In Germany, like in other European countries, the legislator has imposed 2021 significant requirements on pig farmers for new buildings, as well as for existing buildings after a transition period. Farrowing must take place in pens in the future with a minimum pen area of 6.5 m2, and fixing the sow in farrowing crates is only permitted for a maximum of 5 days around the expected time of birth. However, breeding and housing systems have developed and adapted in parallel over decades. Therefore, in addition to the many questions regarding structural and organizational implementation, the question arises for this study how free farrowing affects sows and their piglets around farrowing. In experimental approaches, we monitored a total of 115 farrowings at the pig facility of the Research Institute for Farm Animal Biology (FBN). Sows of two breeds, German Landrace (n=44) and German Saddleback (n=37), farrowed either once or twice in a farrowing crate (1 m²) or in a farrowing pen (6.5 m²). The birth processes were documented and repeated blood samples were taken from sows (n=46, from 2 days (d) before to 4d after farrowing) and piglets (n=144, on d0, d1, d4, d20, d29). The influences of birth induction and piglet weight were also considered. It was found that essential hormones for birth (oxytocin, prostaglandin F metabolites), metabolism (glucose, NEFA, BHB), or stress (cortisol, adrenaline, noradrenaline) in sows before, during, and after birth were not significantly influenced by the type of housing over the entire period. Only the stress hormone adrenaline was significantly elevated in sows in crates on particular days following birth. The interfarrowing intervals also did not differ between the housing systems (median of 18.4 min in crates and 16.8 min in pens). It was noticeable that 46% of German Landrace animals experienced at least one birth interruption of 60 minutes or more, while this occurred in only 12% of Saddleback animals. However, the occurrence of dystocia was not influenced by the housing systems. When assessed for vitality using the APGAR score modified according to Randal (1971; 0 to 8 points), the piglets showed comparably good vitality immediately after birth, with an average of 7.5 out of a possible 8 points in both housing systems. Although the piglets reached the udder significantly earlier in sows kept in crates, with a median of 13 minutes compared to 18 minutes in the pens, the first colostrum intake at the teat occurred at a median of 19.5 and 22 minutes in the crates and pens, respectively, which was comparable. Successful colostrum intake could be demonstrated by the total protein in the piglets' blood. Piglets in both housing systems showed a similar and good colostrum supply on the first day of life, with 5.3 ± 0.1 and 5.1 ± 0.1 g/dL total protein in the plasma. Until weaning, we observed comparable weight development in both housing systems in this study. Overall, we observed piglet losses of 14.1% of piglets born in crates and 15.4% in pens for German Landrace sows, and 16.0% and 15.3% in these housing systems for German Saddleback pigs, with losses mainly occurring up to the third day of life. According to our research, switching to specially designed, animal friendly farrowing pens should result in a physiological birth process and no negative effects on piglets or sows are to be expected. However, different pen designs must be taken into account and, in individual cases (e.g., aggressive sows), the option of briefly restraining the sow should be used to reduce early piglet losses.

Balancing productivity and welfare to improve resilience in modern pig farming systems

K. O'Driscoll[1]
[1] Teagasc, Pig and Poultry Development Department, Animal and Grassland Research and Innovation Centre, P61 RX43 Fermoy, Ireland

The term resilience refers to the capacity of a system to respond to both extreme disturbances, and chronic stress. A resilient system should be able to absorb such impacts, then recover and adapt. Although resilience is often considered in the context of how a system can respond, preparation for such events is an essential component of resilience. During the last century both pig farming systems, and pigs themselves, have become extremely efficient in their operational and performance capacity when all is 'going well'. Breeding strategies have produced sows that can deliver ever increasing numbers of piglets, and both advances in genetics and nutritional science have meant that the growth rate and efficiency of pigs has had a similar upward trajectory. These improvements are generally considered a success story for the industry, yet the infrastructure and management systems that have co-evolved to maximise these gains in performance have resulted in pigs approaching the limits of their capacity for resilience. We are entering an era where the resilience of both pigs, and the farming systems in which they live, are likely to be further tested; potential disruptions and stressors are likely to arise from a multitude of sources, including the threat of emerging disease (e.g. ASF), environmental challenges (e.g. extreme weather events), and consumer and political pressure to raise welfare standards. Although it cannot be measured directly, there are many ways to estimate resilience in farm animals, from immunological measurements, to measuring stress response or performance. One of the easiest and most specific methods to estimate resilience in pigs is to consider their propensity to perform tail biting behaviour. Although a common problem in pig production, it is considered an abnormal behaviour because it is rarely performed even by modern commercial strains of pigs when managed in an environment similar to that within which the species evolved. Widely accepted to be a symptom of the experience of chronic or acute stress, it emerged as a systemic issue during the early 20th century when pig production intensified. To control it, the docking of pigs tails became a routine practice. This enabled pigs to be managed in a way that maximised economic efficiency; recommendations and regulations regarding stocking densities, feeder space allowances etc. were subsequently developed using docked pigs as the model. However, the removal of the tail did not reduce stress levels per se, it simply reduced the likelihood of this behavioural response occurring. Moreover, tail biting continues to be a significant production problem, indicating that pigs are often unable to successfully cope with stressors. There are two approaches which could be employed to resolve this mis-match between the pig and their environment. The first is to improve the resilience of the pigs themselves; this is of increasing importance as an industry breeding goal. Measures of tail damage could aid in estimating the ability of the animals to cope with stressors and 'bounce back' to optimal production levels. The second is to redesign pig rearing systems so that they better meet the behavioural needs of pigs, reduce the need to dock, yet remain economically viable. This approach aligns with meeting the requirements of the EU pig directive (Council Directive 2008/120/EC), and could also address consumer and citizen concerns regarding the welfare of farmed animals. Reducing the pigs' allometric load in this way will increase their resilience, improve the robustness of farming systems, and potentially provide opportunities for diversification into novel rearing strategies that could add value to the final product.

Castration alternatives in European pig production: Welfare outcomes, technical feasibility and adoption trends

M. Almeida[1], J. Teixeira[1], D. Monteiro[1], V. Pinheiro[1], S. Silva[1], V. Courboulay[2], P. Chevillon[2]
[1] UTAD, Quinta de Prados, 5000 Vila Real, Portugal, [2] IFIP, Lieu-dit La Motte Au Vicomte, 35650 Le Rheu, France

Surgical castration of male piglets remains a widespread practice in Europe to prevent boar taint, despite well-documented welfare concerns associated with acute pain responses, stress-related behaviours and tissue inflammation. The EFSA Scientific Opinion on pig welfare recommends either systematic use of effective anaesthesia and analgesia or transition toward entire male production or immunocastration. However, adoption of these alternatives varies considerably across Member States due to differences in slaughter weight, market requirements, regulatory frameworks and consumer acceptance. Within the Horizon Europe project WelFarmers, a structured review was conducted combining peer-reviewed literature, grey literature, national regulations and updated country-level data (2009–2024). The objective was to evaluate technical constraints, welfare implications and implementation trends of alternatives to painful surgical castration. Data indicate substantial divergence across Europe. Between 2016 and 2024, surgical castration decreased from approximately 80% to 49% in France, with entire male production rising to 48%. In Portugal, castration declined from 12.5% to <5%, and more than 50% of males are currently reared entire. Conversely, surgical castration remains above 90% in several Member States, illustrating persistent structural heterogeneity. From a technical perspective, intratesticular and subscrotal administration of local anaesthetics (e.g., lidocaine or mepivacaine at 0.5 mL per testis, 5–10 min prior to surgery) significantly reduces behavioural pain indicators compared to surgery without anaesthesia, although complete pain suppression is not achieved. Analgesics (e.g., meloxicam, flunixin) mitigate post-operative inflammatory responses but show variable effects on acute pain behaviours. Immunocastration (two-dose anti-GnRH vaccination protocol, second injection 4–6 weeks before slaughter) effectively reduces boar taint compounds and modifies behaviour after the second dose but increases labour input and requires strict compliance and operator safety measures. Entire male production eliminates surgical pain but is associated with increased mounting and aggression, particularly at slaughter weights around 110 kg, requiring stable grouping, sex separation and adapted feeding strategies. Overall, measurable progress toward castration avoidance is occurring in several EU countries; however, technical feasibility remains strongly conditioned by production systems and market structures. Harmonised pain mitigation protocols and context-adapted adoption of alternatives represent realistic pathways for improving welfare without compromising productivity. Duration of muscle excitations during inert gas stunning of slaughter pigs: Do they influence meat quality?

J. Gelhausen[1], I. Wilk[2], D. Mörlein[1], J. Tetens[1], J. Knöll[2]
[1] Georg-August-University, Department of Animal Science, Burckhardtweg 2, 37077 Göttingen, Germany, [2] Friedrich-Loeffler-Institute, Institute of Animal Welfare and Animal Husbandry, Dörnbergstr. 25/27, 29223 Celle, Germany

Stunning pigs with inert gases is considered advantageous from an animal welfare perspective compared to stunning with high concentrations of carbon dioxide (CO2). However, it has not yet been implemented in commercial slaughterhouses as for instance, concerns regarding meat quality persist. These include lower pH45 values, which is suggested to be caused by longer or stronger muscle excitations during stunning. In this context, blood lactate can serve as an indicator of acute muscle activity and metabolic state. We therefore hypothesized that longer excitation durations (ED) would be associated with elevated blood lactate levels and reduced pH45. The present study aimed to investigate these relationships in the context of inert gas stunning. Data were derived from the second experiment of the project "Testing inert gases in order to establish replacements for high concentration CO2 stunning". A total of 900 crossbred slaughter pigs (slaughter weight M = 98 kg, SD = 8 kg) were stunned on 14 slaughter days using argon (Ar), a nitrogen-argon mixture (N2-Ar), or at least 90% CO2 (control). The experiment was conducted with a commercially used dip-lift system retrofitted with a new gassing technology achieving a residual O2 concentration of < 1%. Pigs were stunned in pairs and the process was video recorded. ED was evaluated by two observers using randomized video sequences. Blood samples collected during exsanguination, were analyzed for lactate concentration. Meat quality traits (pH & temperature) were assessed in the M. longissimus thoracis et lumborum (LTL) and M. semimembranosus (SM) at 45 min and 24 h p.m.. The final dataset comprised 244 (Ar), 244 (N2-Ar), and 246 (CO2) pigs with all traits recorded. Inert gas stunning resulted in no significant reduction in the SM pH45, while for LTL a reduction ($P < 0.001$) was found between the inert gases and CO2. Even though this reduction was significant, the numerical differences did not affect other meat quality parameters as no pale, soft, and exudative meat was detected. However, blood lactate concentrations and excitation durations showed significantly higher values in pigs stunned with inert gases, whereas CO2-stunned pigs exhibited lower lactate levels and shorter excitation durations ($P < 0.05$). To find indicators of a relationship between ED, blood lactate concentration, and pH45, correlation analyses were conducted. ED was only weakly correlated with pH45 values in the SM across inert gases ($r > -0.2$, $P < 0.05$) and was statistically significant solely in the N2-Ar group for the LTL. Similarly, only a weak correlation was found between ED and lactate for N2-Ar ($r < 0.2$, $P < 0.05$). In contrast, blood lactate concentrations were significantly negatively correlated with pH45 values for all gases. CO2 and Ar exhibited moderate negative correlations ($r < -0.2$, $P < 0.05$), whereas a weak correlation for N2-Ar was found ($r > -0.2$, $P < 0.05$). Taken together, these findings suggest that excitation duration is only a coarse measure for muscle pH variation. Instead, lactate production appears to have a stronger correlative relationship with muscle pH, indicating that strength of muscle activity needs to be taken into account. To better understand the physiological mechanisms linking inert gas stunning to metabolic responses and p.m. muscle physiology further investigations are needed. Understanding the mechanisms behind the pH45 reduction in valuable muscles during inert gas stunning could ease the future implementation of this method in commercial slaughterhouses.

Longitudinal study: Swine inflammation and necrosis syndrome in suckling piglets is associated with tail length and integrity in slaughter pigs of two organic farms in the Netherlands

K. Koenders - Van Gog[1], E. Krooshoop[1], T. Wijnands[1], M. Lechner[2], G. Reiner[3]
[1] Lintjeshof Veterinary Practice, Swine, Pannenweg 200, 6035 Nederweert, Netherlands, [2] UEG Hohenlohe, Am Wasen 20, 91567 Herrieden, Germany, [3] Justus-Liebig-University Giessen, Clinic for Swine—Herd Health Management and Molecular Diagnostics, Ludwigstrasse 23, 35392 Giessen, Germany

The purpose of the study was to evaluate whether clinical signs of the Swine Inflammation and Necrosis Syndrome (SINS) in piglets from organic farming systems could serve as a prognostic indicator for later tail health. Therefore piglets from two organic farms in the Netherlands were longitudinally studied from birth until slaughter. Additionally, the association between hematological parameters in weaners and the clinical outcome at different ages was tested. A total of 361 piglets with long tails from two closed organic farms in the Netherlands were digitally identified and clinically assessed for signs of inflammation and necrosis (SINS) as suckling piglets and again as weaners. The tail base, tail tip, teats, ears, coronary bands, and heels were examined. Tail integrity was assessed again during the finishing period, and tail length and integrity were evaluated at the slaughterhouse. Individual carcass weight, backfat thickness, and muscle thickness were recorded. Complete datasets were available for 200 pigs. Blood samples from 35 pigs were collected at weaning and analyzed hematologically. Signs of SINS were detected in 80% of suckling piglets and 24% of weaners. Small tail lesions without obvious biting were found in 10.3% of finishers. All finishers with tail wounds, had shown signs of SINS as suckling piglets ($P = 0.011$). Among examined slaughter pigs, 76% exhibited a tail length >30 cm, while 23% had tail lengths between 23 and 30 cm. A significant effect of the SINS score in suckling piglets on the prevalence of tails >30 cm at slaughter was detected ($P < 0.001$). The probability of exhibiting a tail >30 cm decreased with increasing SINS scores recorded during the suckling phase: 99.9%, 89.0%, 68.7%, 83.6%, 58.8%, and 0% for SINS score groups 0 (lowest scores) to 5 (highest scores), respectively. There was an association between tail length and tail lesions at slaughter. In pigs with tails >30 cm, 90.6% showed no abnormalities, compared with 67.9% in pigs with tails <30 cm ($P < 0.001$). No associations were detected between the SINS score of suckling piglets and the occurrence of healed wounds or local size deviations of the tail at slaughter. However, the SINS score was significantly associated with the absence of any tail abnormalities. No correlations were found between SINS scores and carcass parameters. Hematological indicators of white and red blood cells at weaning were significantly associated with SINS signs observed during the suckling phase. With increasing SINS scores, the following significant changes were observed: an increased monocyte percentage, a decreased thrombocyte count, a decreased erythrocyte count, a decreased lymphocyte count, a decreased hematocrit and a decreased red cell distribution width. Clinical signs of inflammation and necrosis in suckling piglets were associated with tail length and integrity at slaughter, confirming the suitability of SINS as a prognostic indicator for later tail damage. This indicator can be used as an animal-based measure to improve pig welfare, as reflected by tail integrity. Hematological parameters in weaners were correlated with SINS signs in suckling piglets, supporting the inflammatory nature of the syndrome. The associated hematological parameters may serve as supportive diagnostic tools for the prevention and evaluation of SINS in pigs.

Status quo of pre-weaning mortality in organic farms in Germany

H. Lickfett[1], W. Vogt-Kaute[2], E. Hofinger[3], M. Kötter-Jürß[4], G. Schnieders[2], D. Mai[3], A. Vernunft[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany,
[2] Öko-BeratungsGesellschaft mbH – Consulting for Naturland, Eichethof 1, 85411 Hohenkammer, Germany,
[3] Naturland - Association for Organic Agriculture e.V, Kleinhaderner Weg 1, 82166 Gräfelfing, Germany, [4] Bioland Practical Research Ltd., Kaiserstr. 18, 55116 Mainz, Germany

Pre-weaning mortality presents a serious economic and ethical problem. The expectations for organic farms are therefore particularly high. This study aims to describe the current situation on farms and subsequently identify causes and possible solutions by exploring the housing system on farm, fertility data and using microbiological diagnostics. Therefore, a comprehensive questionnaire was developed covering base data, farm organisation and management, genetics and, if applicable, vaccinations programs of sows and piglets, castration procedures, causes of mortality, documentation, structural conditions, feeding of sows and piglets, management during the peripartal time and piglet rearing. From December 2024 to September 2025, 62 farms with five to 960 sows from Germany have been included. On average, they had space for 125 ± 20 sows, but only 112 ± 20 sows were kept. This may be due to economic factors, but also to uncertainties regarding animal diseases. Both, modern genetics and old breeds were used. Most farms (85.5%) housed pigs in stables with outdoor access around parturition and during the suckling period. Size and design of the pens varied greatly. Only 4.8% of farms had outdoor housing, and 9.7% of farms had a mixed form of indoor and outdoor housing. Regardless of housing ($P > 0.05$), farms reported pre-weaning mortalities between 5.9% and 36.0%, on average 16.4 ± 0.8%. However, pre-weaning mortality could not be precisely determined for each farm, so farms with unverified data were excluded from this analysis. Therefore, to minimise pre-weaning mortality in some farms, it is necessary to fully document and record the extent and causes of pre-weaning mortality in order to address the problem. Because newborn piglets have to deal with a lot of challenges and the parturition process itself also affects the piglets' survival later on, parturition monitoring is important. However, the intensity varies between farms. Some farms use video monitoring, while most check the sows occasionally during the day. All farms stated that they provide obstetric assistance themselves, when necessary, on 30% of farms, a veterinarian is also called if needed. Different management measures could improve the piglet survival. For example, 35.5% of the farms places the piglets are placed at the udder to ensure colostrum intake, or cross-forstering is performed at 93.6% of the farms. The level of implementation of these and other measures varies between farms. While some provide intensive care for piglets in the first few days of life, others only carry out absolutely necessary procedures. In summary, it should be noted that mortality rates range from 5.9% to 36.0%. The conditions in organic piglet production are very heterogeneous, which requires individual solutions to reduce pre-weaning mortality. It is essential to record extent and causes of pre-weaning mortality in order to systematically remedy problems. In a second part of the project, swab and faecal samples will be taken from a total of 20 farms, to determine early microbiota colonisation and establish possible links to piglet health and pre-weaning mortality The project is funded by the Federal Ministry of Food, Agriculture and Rural Affairs (BMLEH) and managed by the Federal Office for Agriculture and Food (BLE) as part of the Federal Organic Farming Programme (acronym: ProFerkel).

Histopathological characterization of ear damage caused by ear biting and aggression in recently weaned pigs

L. Markland[1,2], L. Boyle[1], F. Leonard[2], K. O'Driscoll[1], P. Kelly[2]
[1] Teagasc, Pig and Poultry Research and Knowledge Transfer Department, Moorepark, P61C696 Fermoy, Ireland, [2] University College Dublin, School of Veterinary Medicine, Belfield, D04V1W8 Dublin, Ireland

Ear lesions (i.e. bite marks, scratches, ear necrosis) are common in pigs in intensive production systems. Aggressive behaviour is considered the primary cause of ear scratches, which are hypothesised to contribute to ear necrosis by providing an avenue for bacteria to enter the ear. Ear-directed oral manipulation (e.g. biting, suckling, nibbling, chewing) is thought to result in bite marks, which are often not as macroscopically visible as scratches. Nevertheless, they could also predispose the pig to ear necrosis if the underlying tissue is damaged. Ear necrosis is considered the most severe type of ear lesion, as it can result in complete degradation of the pinna. This study recorded behaviour in pre-weaned piglets, then compared "bite marks" arising from ear-directed oral manipulative behaviour, and "scratches" caused by aggressive behaviour, using histopathological methods. Sows and piglets in conventional farrowing crates were managed according to routine farm practices. Twenty litters (n=293 piglets) were observed from birth once/wk for 4 wks. All occurrences of ear-directed oral manipulation were recorded during five 3-min observation sessions (n=15 min/litter/wk). Pigs were mixed at weaning (28d of age) into pens of 10 pigs. On d4 post-weaning 40 pigs were euthanised. Both ear pinnae were collected, and biopsies of the ear were taken when bite marks or scratches were observed. In total, 20 biopsies from 10 pigs (2 samples/pig: 1 bite mark and 1 scratch on the same ear) were processed and graded for changes in 17 histopathological parameters on a scale of 0-3 (0=absent, 1=mild, 2=moderate, 3=severe). For each parameter, diagnostic agreement between paired lesions on the same individual pig (bite vs scratch) was determined using Cohen's weighted kappa (K) and exact percent agreement (proportion of pigs where both damage types received the same score). Differences between damage types (across all pigs) were tested using the Wilcoxon rank-sum test. All litters performed ear-directed oral manipulation pre-weaning and most (12/20 litters) even in the first week of life (mean±SD; wk 1: 0.08±0.090, wk 2: 0.33±0.217, wk 3: 0.39±0.328, wk 4: 0.47±0.275 manipulations per pig/15-min/litter). Dermal fibrosis, vasculitis, and vascular hypertrophy were absent in all samples. Mild orthokeratotic hyperkeratosis, mild to moderate epidermal hyperplasia, mild perivascular inflammation, mild to moderate oedema, and neutrophil presence were present in all samples. Within the same pig, 8 parameters had a high (>50%) percent agreement, while the K value was poor for all parameters (range: -0.18 to 0.41, all $P>0.05$) across bite marks and scratches. When damage types were grouped across all pigs, scratches had higher scores than bite marks for epidermal necrosis, clefting, pustules, exocytosis, serocellular crusting, and oedema (all $P<0.05$), while scores were similar for the remaining 8 parameters ($P>0.05$). Although ear-directed oral manipulation in piglets caused minimal macroscopic damage, these findings indicate similarity with scratches, which are much more visible, in the type of tissue damage at histopathological level. This study also confirmed that pigs perform ear-directed oral manipulation as early as 1 week of age and continue to perform the behaviour throughout the suckling period. Confirmation that early life ear-directed oral manipulative behaviour results in histopathological lesions suggests a possible influence of this early life behaviour on post-weaning development of ear necrosis and warrants further investigation.

Preweaning mortality in laboratory mouse breeding: an animal science and veterinary perspective on a 3R challenge

High preweaning mortality is a major welfare and economic problem in laboratory mouse breeding. This talk will present a summary of more than a decade of research into this often-overlooked problem. Despite greater environmental protection, preweaning mortality in mice is substantially higher than for litter-bearing mammals reared for food production animals. In the first large multi-site study under practice conditions, we showed that mortality varies greatly between facilities and is substantially larger than reference data. In data from 35,000 litters of C57BL/6 mice we found 39% preweaning mortality in one facility and 14% in the other, whereas reference data is 8%. This study also identified litter overlap, advanced dam age, and very small or very large litters as major risk factors for pre-weaning death (Morello et al 2020 doi.org/10.1371/journal.pone.0236290). Different inspection routines and record keeping may partly explain the disparity in results. Comparison of data from high-resolution behavioural monitoring from video recordings with standard pup counting methods has demonstrated that routine daily cage checks substantially underestimate perinatal deaths by underestimating the number of pups born Analysis of this video footage also indicates that unlike the popular belief that females kill pups, infanticide is rare and when pups are lost it is mainly through cannibalism of pups that were already dead (Brajon et al 2021 https://doi.org/10.3390/ani11082327). Parallel post-mortem analysis using a standardized neonatal necropsy protocol provide information on causes of death (Capas-Peneda et al 2020 doi.org/10.1177/0023677220983374). Preliminary results show that among pups that were born alive but die shortly after birth, failure to obtain milk (stomachs without milk spots) is common, sometimes with air in the stomach suggesting a failed attempt to suckle (Capas-Peneda et al 2023 10.1016/j.jcpa.2024.03.079). Appropriate temperature and nest quality can mitigate some of the risks associated with the social configuration in the cage (Morello et al 2024 http://dx.doi.org/10.1038/s42003-024-06654-z). Our most recent results also suggest that managing the social configuration by moving periparturient females may be a successful strategy to avoid risky litter overlap and improve pup survival. From the perspective of our team of animal scientists, biologists and laboratory animal veterinarians, it is surprising that so little attention has been paid to the problem of early pup mortality. The impact on the logistics of research animal facilities is substantial, especially taking into consideration that often the entire litter is lost. Mortality happens mainly within the first three days after birth. The practice in many animal facilities not to inspect breeding females until several days after parturition likely means that many animal facilities are unaware of the problem. Also, whereas many animal facilities have digital systems for animal management, they typically lack human resouces capacity to extract data from these systems to inform management practice.

Animal welfare definitions, frameworks, and assessment tools: Advancing the measurement and laying the foundation for improved animal welfare through a three-step approach

F. J. Van Der Staay[1,2], V. C. Goerlich[1], F. L. B. Meijboom[1], S. S. Arndt[1]
[1] Faculty of Veterinary Medicine, Utrecht University, Population Health Sciences, Division Animals in Science and Society, Yalelaan 2, 3584 CM Utrecht, Netherlands, [2] University Medical Center, Brain Centre, Heidelberglaan 100, 3584 CX Utrecht, Netherlands

Animal welfare assessment tools are being developed and existing tools are being modified to make them applicable to multiple species living under different management and housing conditions. These assessments should produce reliable, consistent and reproducible results that can be used to guide animal welfare-related activities. Here, we discuss the key steps for developing, validating and applying animal welfare assessment tools. These steps are: 1) agreeing on a definition of animal welfare; 2) formulating and agreeing on a framework for evaluating animal welfare; and 3) developing and validating animal welfare assessment tools based on the adopted welfare definition and evaluation framework(s). However, the development of many of the assessment tools currently in use has not systematically followed this three-step approach, and the theoretical basis on which an assessment tool is developed remains unclear. Both theoretical or conceptual frameworks—which structure the research and indicate which aspects are prioritized—and ethical frameworks—which clarify the underlying moral stance—should be taken into account. Increasing transparency and clarity regarding the underlying definitions and framework will make it more likely that the resulting welfare assessment tools will give similar weight to the aspects considered relevant to animal welfare. The proposed three-step approach should lead to consistent welfare assessment results, facilitate the positioning of these tools within ongoing welfare discussions and clarify which welfare concepts have been applied when developing the assessment tool.

Rethinking animal welfare through the microbiota: early maternal microbial contact builds immune resilience in commercial broilers

H. Zhao[1], A. De Ceuster[1], M. Z. Akram[1], L. Comer[1], E. Fako[1], M. Corion[1], N. Everaert[1]
[1] KU leuven, Department of Biosystems, Kasteelpark Arenberg 30, 3001 Heverlee, Belgium

Modern commercial broiler production relies on centralized incubation and rearing, which significantly improves production efficiency. However, this practice separates chicks from hens, depriving them of their natural early life environment. This separation disrupts the vertical transmission of microbiota, resulting in a delayed and incomplete establishment of the early life gut microbiota, which consequently becomes dominated by environmental microbiota. Research indicates that early gut colonizers are not passive residents but key regulators of host physiological functions. Increasing evidence highlights their role in improving behavioral welfare by reducing fearfulness and mitigating feather pecking. Beyond these behavioral effects, the early gut microbiota also plays critical roles in intestinal barrier function, immune maturation, and nutrient metabolism. Given the critical impact of the early gut microbiota on host health, the concept of animal welfare should extend beyond physical comfort to include natural microbial colonization. Consequently, early microbiota intervention in commercial settings provides a feasible welfare strategy aligned with the 3Rs principles. Rather than relying on medical interventions after disease onset, this proactive approach utilizes early microbial transfer to establish a stable health foundation from the beginning. To evaluate this concept, we performed an experimental model that exposed newly hatched chicks to maternal microbiota to mimic the natural way of microbiota acquisition. We investigated whether this early contact could modulate gut microbiota and metabolite production to enhance resilience against a lipopolysaccharide (LPS) induced immune challenge. Our findings demonstrated that maternal microbial contact significantly increased cecal microbial diversity and altered community structures. These changes were accompanied by enhanced production of cecal volatile fatty acids and modulated serum tryptophan metabolism. Notably, maternal microbial contact significantly interacted with the LPS challenge, effectively modulating LPS induced alterations in both microbial and metabolite profiles. Independent of the LPS challenge, maternal microbial contact upregulated genes related to intestinal barrier integrity and antioxidant defense. Conversely, the LPS challenge independently increased the expression of proinflammatory cytokines and impaired mucosal barrier function. In conclusion, early maternal microbial contact effectively modulated the gut microbiota and metabolite production, representing a potential strategy to improve immune resilience in broilers. This demonstrates that integrating natural biological mechanisms into commercial husbandry is not merely a health intervention, but also a potential welfare improvement.

Ruminant specific multi enzymatic in vitro model accurately predicts in vivo feedstuffs degradability and digestibility to phase out of fistulated reference trials

C. Pineda Vadillo[1], L. Drouet[1], C. Favier[1], C. Vaz Torralba[1], N. Couvreur[1], A. Brame[1], S. Klein[1]
[1] MiXscience, RID, 2 avenue Ker Lann, 35172 BRUZ, France

Precise evaluation of forages and raw materials nutritional content is essential for designing cost-effective and sustainable ruminant diets. Organic matter digestibility (OMD) and ruminal dry matter (DMD) and nitrogen (ND) degradability parameters are key determinants of ruminant diet's nutritional value and zootechnical performance. Historically, reference values for DMD, ND and OMD have been established using fistulated animals through in sacco and gas test (HFT) methods respectively. However, these approaches raise ethical questions.In vitro enzymatic models represent a credible alternative to in vivo assays, although existing methodologies are outdated and fail to characterize nutrient degradability kinetics up to 48 hours. Therefore, the goal of this study was to develop an in vitro enzymatic model capable of accurately predicting in vivo ruminal degradability kinetics and OMD for a wide range of feedstuffs. In vitro model parameters (enzyme-to-substrate ratio, stirring speed, pH and enzymatic activities) were established based on ruminal fluids measurements and supplemented with data from scientific literature. Ruminal fluid samples were collected from six fistulated cows in compliance with ethical requirements (APAFIS #21558). A series of experimental designs was then conducted to identify key conditions, notably enzymes dosages and optimal pH conditions. The resulting enzyme cocktail comprises more than 20 distinct enzymatic activities (e.g., cellulolytic, hemicellulolytic, xylanolytic). Once parameters set, the in vitro model was applied to 29 feedstuffs chosen to cover the high diversity of ruminant diets (forages, oilseed meals, cereals and by-products) and selected from our in vivo trial repository. Residues were analyzed after 2, 4, 7, 24 and 48 hours of incubation to generate digestion kinetic curves. As an initial validation, the in vitro model's performance was assessed by 1) measuring repeatability (3 replicates) and reproducibility (2 operators, 2 days each) on 16 different feedstuffs with average CV of 1.1% and 2.3%, respectively; 2) comparing in vitro vs in vivo outcomes using linear regression model. The coefficient of correlation (R_2) was calculated on the 4 hours incubation time point of the kinetic curve for DMD parameter with high performance ($R_2 = 0.84$). Building on this proof of concept, further development was performed on the 29 feedstuffs and 30 different samples of grass silage to develop a specific prediction model. Four machine learning algorithms (Elastic Net, PLS, Ridge and multiple linear regressions) were trained on 25 samples to predict in vivo DMD and ND kinetics from in vitro curves and silage's chemical composition. Model performance on predictive accuracy was evaluated by the root mean square error of prediction (RMSEP) on a held-out test set of 5 samples. On the 29 feedstuffs, predicted DMD and ND kinetics were strongly correlated with in vivo curves ($R^2 = 0.97$ and 0.94 respectively) and the global hierarchy among and within the feedstuffs was preserved. For grass silage, the best-performing machine learning model achieved RMSEP values of 4.2% for DMD and 3.3% for ND. The most accurate prediction of in vivo OMD yielded an RMSEP of 1.4 % for OMD. Although ingredient specific models remain to be developed for other feedstuffs to expand the range of feeds evaluated with this new method, these results demonstrate the strong potential of coupling advanced in vitro enzymatic methods with mathematical modeling for accurately predicting in vivo nutritional values in ruminants to replace fistulated cows and address public concern on animal testing.

Accurate prediction of apparent metabolizable energy of feedstuffs using a poultry-specific in vitro digestion model

C. Pineda Vadillo[1], C. Favier[1], J. F. Faivre[1], N. Bernard[1], K. Le Calve[1], N. Couvreur[1], S. Klein[1]
[1] MIXSCIENCE, RESEARCH AND DEVELOPMENT, 2 AVENUE DE KER LANN, 35172 BRUZ, France

Accurate evaluation of feedstuffs' energy value is essential for cost-efficient and sustainable poultry feed formulation, particularly to facilitate the inclusion of alternative raw materials such as by-products. Apparent metabolizable energy is usually determined in vivo, which is costly, time-consuming, and relies on animal experimentation. In contrast, in vitro digestion models are widely used in human nutrition but remain underdeveloped for poultry, despite their strong potential to support the 3Rs principle, and enable rapid feedstuffs screening. The goal of this study was to develop predictive models of in vivo apparent metabolizable energy for a wide range of feedstuffs, based on in vitro digestible energy (IVDE), measured with our poultry-specific semi-dynamic digestion model. In vitro model parameters (enzyme-to-substrate ratios, pH and enzymatic activities) were established using measurements on gastrointestinal (GI) contents, further supplemented with data from scientific literature. GI samples were collected from roosters (n=10) and broiler chicks (n=36) exclusively to parameterize the assay and in compliance with ethical approval requirements (APAFIS#21033-2019061206096709v2). Routine IVDE determinations are subsequently performed using an in-house developed cocktail of commercial enzymes. A total of 175 raw materials representing the variability of eight major poultry feedstuffs were selected: wheat (n=52), corn (n=36), barley (n=8), soybean meal (n=22), sunflower meal (n=25), rapeseed meal (n=18), wheat DDGS (n=7) and faba bean (n=7). Each raw material was evaluated as a paired in vivo–in vitro sample and analyzed for chemical composition (dry matter (DM), ash, crude protein, ether extract, crude fiber). In vivo apparent metabolizable energy corrected to zero nitrogen balance (AMEn) was measured in roosters according to the European reference method based on total collection (Bourdillon et al., 1990) and ranged from 1650 to 3900 kcal/kg DM. IVDE was measured in triplicate. Data were analyzed using linear models (R software). Model performance was evaluated on a held-out test set, and root mean square error of prediction (RMSEP) was calculated using cross-validation techniques, to assess predictive accuracy on independent raw materials. IVDE repeatability ranges from 1.1% to 2.5% and reproducibility from 1.4% to 3.5%. These values are equivalent, or even slightly better than those measured in vivo. A feedstuff-specific linear model combining IVDE and chemical composition predicts AMEn with a coefficient of determination (R^2) of 0.988 and a RMSEP of 71 kcal/kg DM. By suppressing the feedstuff effect, a global model achieves a R^2 of 0.976 and a RMSEP of 101 kcal/kg DM. This model could be used for new raw materials. These results demonstrate the strong potential of this poultry-specific in vitro digestion model as a reliable tool for predicting in vivo energy value, supporting more efficient and sustainable feed formulation. Beyond AMEn evaluation, this model offers promising perspectives for the assessment of feed additives such as NSP-degrading enzymes.

Validation of an AI-Based Method for Corneal Endothelial Cell Viability Assessment in an ex vivo Porcine Model

G. Salvi[1], O. Balbi[1], M. Penati[1], L. G. De Matos[1], A. Zurlo[1], Y. Dadi[1], R. I. Lazari[1], C. Giudice[1], P. Riccaboni[1], F. Ceciliani[1], G. Servalli[3], F. Gritti[3], C. Gagliano[3], L. Ressel[2], C. Lecchi[1]

S.p.A. Pharmacological Laboratory, Via Guglielmo Marconi 2, 24069 Cenate Sotto, Italy

The success and safety of corneal transplantation rely on accurate quality assessment of donor corneal tissues. Endothelial cell density (ECD) is currently the primary parameter used to evaluate corneal suitability; however, it does not provide a comprehensive assessment of tissue health. The evaluation of endothelial cell viability offers complementary and clinically relevant information, enabling a more reliable selection process. In line with the principles of Replacement, Reduction, and Refinement (3Rs), this study employed an ex vivo porcine corneal model using slaughterhouse by-products, thereby avoiding the use of live animals. As only tissues derived from the food chain were used, no ethical approval was required; all procedures complied with European Eye Bank Association (EEBA) guidelines. A U-Net convolutional neural network (CNN) was developed to automatically classify corneal endothelial cells according to viability status, based on Trypan Blue staining in microphotographs. Images were acquired using a Nikon Eclipse Ts2R inverted microscope at 200X magnification. The dataset comprised 230 images from twenty porcine corneas for model training using Masked Image Modeling (MIM) software, and 25 images from an independent set for validation, with a strict cornea-level split to prevent data leakage. Manual annotations were performed in a blinded manner by a trained operator using ImageJ-Fiji and were used as the Gold Standard for model evaluation. The model was trained to identify three classes: viable cells, non-viable cells, and undefined or out-of-focus regions. During evaluation, undefined areas were excluded from quantitative analysis by masking them from the denominators. The CNN successfully distinguished the three cellular classes, achieving an overall counting accuracy of 91%, with class-specific accuracies of 93% for viable cells and 70% for non-viable cells. In addition to its accuracy, the model markedly reduced processing time from approximately eight hours to a few minutes. Beyond improving efficiency, the automated approach enhances reproducibility and minimizes operator-dependent variability, contributing to methodological refinement. Overall, this study validates an AI-based, image-driven method for endothelial viability assessment in an ex vivo porcine model. By integrating computational analysis with ex vivo methodologies, this approach supports a 3Rs-oriented framework, refines experimental procedures, and reduces animal use in translational ophthalmic research. Further studies involving larger datasets and different imaging systems are planned to improve model robustness and broaden its applicability.

Left-side dominance in laying hens: an investigation of chick lateralization following a 10-week exercise regime

R. Garant[1], B. Tobalske[2], N. Van Staaveren[1], D. Powers[3], T. Widowski[1], B. Willie[4,5], A. Harlander[1]
[1] University of Guelph, Department of Animal Biosciences, 50 Stone Rd E, N1G 2W1 Guelph, Canada, [2] University of Montana, Division of Biological and Biomedical Sciences, 32 Campus Dr, MT 59812 Missoula, United States, [3] George Fox University, Department of Biological and Molecular Sciences, 414 N Meridian St, OR 97132 Newberg, United States, [4] Utah State University, College of Veterinary Medicine, Old Main Hill, UT 84322 Logan, United States, [5] Shriners Hospital for Children Canada, Research Centre, 1003 Bd Décarie, H4A 0A9 Montréal, Canada

Effective, coordinated wing-flapping flight is critical for safe movement and collision avoidance in skeletally vulnerable laying hens living in commercial aviary systems. Variation in contralateral neural control has been documented in domestic pullets, including right-foot preferences (indicative of left-hemisphere dominance of the hindlimbs) and a tendency to turn left (right-hemisphere dominance over the wings). These asymmetries may reflect broader motor lateralization, potentially influencing flight biomechanics and muscle development. Although early-life exercise can promote musculoskeletal growth, its effects on forelimb motor lateralization remain unclear. Thus, this study investigates whether controlled flapping descent (CFD) training induces asymmetric flight muscle development (as evidence of lateralization and motor modularity) and improves keel bone traits. A total of 168, day-old female chicks (84 white, 84 brown), were allocated to 12 pens (14/pen), randomized and stratified by strain. Within each pen, 7 chicks were assigned to CFD training and 7 to control (CON); the experimental unit was the individual bird. CFD training occurred within each pen and involved catching all chicks and placing CFD chicks individually onto a 1.2 m platform to descend onto a 20-cm-high soft-landing mat. Training occurred 5 days/week from 1–10 weeks of age, starting at 1 descent/day and increasing by 1 every two days. At 11 weeks, bodyweight, flight muscle thickness and keel bone traits (ossification %, total area) were measured by a blinded observer via ultrasound and radiography. Effects of treatment and strain were analyzed using a generalized linear mixed model in SAS, including their interaction as fixed effects, pen as a random effect, and bodyweight as a covariate. This study was approved by the University of Guelph Animal Care Committee (AUP # 5173). The left pectoralis (PEC) of CFD pullets was significantly thicker than CON pullets at 11 weeks of age ($p=0.0005$). Additionally, CFD chicks exhibited a greater left PEC:SUPR (supracoracoideus) ratio ($p = 0.0005$) and increased left PEC thickness relative to body weight ($p = 0.0002$) compared with CON chicks. CFD predominantly stimulated the PEC, responsible for the downstroke, while the SUPR, which drives the upstroke, appeared comparatively less involved. Observed hypertrophy of the left PEC may indicate coordinated motor lateralization, whereby established right-leg dominance is associated with enhanced activation of the left wing. White-feathered pullets showed greater flight-supporting development than brown pullets: thicker left and right PEC and SUPR muscles, larger keel areas, and a greater proportion of keel ossification (all $p<0.0001$). These findings indicate lateralized development of the flight muscles, particularly hypertrophy of the left PEC in pullets, aligning with previously reported right-foot dominance. This further supports the theory of contralateral hemisphere dominance of the hind- and fore-limbs. In aviary housing systems, recognizing such lateralization and motor modularity could guide decisions on perch configuration, ramp alignment, and flight pathway design to better accommodate natural movement patterns.

Implementation of flight-maneuver training in commercial rearing: No extra energy costs

T. Burwell[1], D. Powers[2], R. Garant[1], B. Willie[3], B. Tobalske[4], A. Harlander[1]
[1] University of Guelph, 50 Stone Rd East, N1G2W1 Guelph, Canada, [2] George Fox University, 414 N. Meridian St, 97132 Newberg, United States, [3] Utah State University, 0100 Old Main Hill, 843220-0100 Logan, United States, [4] University of Montana, 32 Campus Dr, 59812 Missoula, United States

Controlled flapping descent (CFD) is a type of locomotion characterized by wing flapping during descent from an elevated surface. Training laying-hen pullets to complete CFDs is proposed to strengthen flight muscles, maneuverability and potentially reduce keel bone injuries/fractures (KBF). However, the effect of such training regimens on energetic cost is unknown. Evaluating the effects of training regimens on energy expenditure is critical to determine whether pullets have sufficient energetic capacity to support growth, development, and subsequent egg production at sexual maturity. The doubly labeled water (DLW) method is commonly used to quantify daily energy expenditure (DEE, kJ/day) in freely moving birds. Since chicken flight muscles are anerobic, and support short, explosive flights, we hypothesized that CFD training would not increase mass-adjusted DEE measured after 10 weeks of CFD training, regardless of improvements in maneuverability in their home environment. In this study, 42 white (W) and 46 brown (B) feathered birds were housed in 12 mixed breed floor pens. Birds were assigned to the trained (T, W: n=19; B: n=24) or untrained group (U, W: n=23; B: n=22), and the distribution of birds in each group was balanced across pens. CFD training began at 6 days of age and continued until 10 weeks of age (WOA) for a total of 46 days. Pullets had training 5 days per week followed by 2 rest days. Training occurred within the pen, and all birds were handled during training sessions. Untrained birds remained in the pen during training sessions to provide social motivation to birds performing CFD. Over the training period, the number of CFDs increased (1 to 15) and rest between successive CFDs decreased (45 second to 5 seconds). Pens were equipped with perches no higher than 15cm during the training period. DEE of W pullets (T: n=19; U: n=23) was measured using DLW over 47 hours at the completion of CFD training (10WOA), and at 19WOA. Pullets received a dose of stable, non-radioactive isotopes deuterium (^{2}H) and oxygen-18 (^{18}O) via intramuscular injection. At one and 48 hours post-injection, blood samples were collected, and the relative elimination of ^{2}H (H2O loss) and ^{1}□O (H2O + CO_2 loss) was used to calculate CO_2 production and thus DEE. Experimental protocols were approved by the University of Guelph Animal Care Committee (Animal Utilization Protocol #5173). DEE outcomes at 10WOA were obtained from the age-specific least-squares means of a repeated-measures generalized linear mixed model (SAS) using a log normal distribution. Training status, age, and average mass (kg) were used as predictors, and pen as a random effect. Only results from 10WOA are presented here. Body mass had a significant positive relationship with DEE ($F=24.11$, $p<0.0001$); therefore, heavier birds expended more energy per day. CFD trained pullets had no increase in daily metabolic load at 10WOA (T=774.78 ± 10.03kJ/day vs. U=779.81 ± 9.37kJ/day, $F=0.17$, $p=0.6791$), indicating that this training regimen does not incur extra energy costs upon completion. Practically, this supports an approach in which CFD activity during rearing could be used to build maneuvering skill without compromising energy available for growth or increasing daily energetic requirements. We are presently examining the effects of CFD training on the prevalence and severity of KBF and maneuvering capacity to test the efficacy of CFD training on the improvement of welfare. Results of such analyses will be presented at the conference.

Isolation of bovine mesenchymal stroma cells from hair follicles as an in vitro model for studies on bovine digital dermatitis

S. Suske[1], F. Jordan[1], A. Hornung[1], F. Rosner[1], B. Brenig[2], H. H. Swalve[1], D. Oelschlägel[1]
[1] Martin-Luther-University Halle-Wittenberg, Institute of Agricultural and Nutritional Sciences, Theodor-Lieser-Str. 11, 06120 Halle (Saale), Germany, [2] Georg August University Göttingen, Institute of Veterinary Medicine, Burckhardtweg 2, 37077 Göttingen, Germany

The principles of the 3Rs (replace, reduce, and refine) provide ethical guidelines for experimental research involving laboratory animals. In our current study, we aim to establish a non-invasive method for isolating bovine mesenchymal stroma cells (MSC) from plucked hair follicles to provide an in vitro cell model. Our experimental approach is novel, as common sources of MSCs in livestock include bone marrow, adipose tissue, or hair follicles obtained from skin biopsies, all of which rely on invasive extraction methods. Our research focuses on the bovine infectious hoof disease digital dermatitis (DD), which has a multifactorial aetiology and a polygenic influence on susceptibility. Through a genome-wide association study, we identified two polymorphisms with significant effects on susceptibility, indicating that specific genotypes were significantly more likely to be affected and to develop chronic lesions. Deeper insights into potentially altered inflammatory processes due to the analysed polymorphisms near CMPK2 (BTA 11) and in ASB16 (BTA 19) could help to develop more animal-specific immunomodulatory therapies. For planned studies on potentially altered cell behaviour and/or cell-cell-communication due to the genotype variants, we intend to use different cell types, such as MSCs, which play an important role in immunological processes during bacterial infections. Additionally, assessing the ability of MSCs to differentiate into keratinocytes is included and may enable us to investigate skin-associated signalling based on this important cell type. To date, MSC cultures from four cattle with different genotype constellations regarding DD have been established. Hair follicles were cultured in vitro with feeder cells until MSC outgrowth occurred after 4-12 weeks. For reliable identification of MSCs, a characterisation analysis was performed based on the recommendations of the International Society for Cellular Therapies (ISCT). Our cells exhibit the typical spindle-shaped morphology, grow adherently on plastic culture dishes, and proliferate stably (over 20 passages). Phenotypic characterization for expression of MSC-specific surface markers was performed with Flow Cytometry. The antibodies successfully labelled bovine MSC surface markers (CD29, CD44, CD90), while not (CD14, CD45) or moderately (CD34) labelling the negative markers. Additionally, expression of the stem cell marker SOX2 was detected via immunofluorescence staining. MSCs should exhibit the potential for chondrogenic, osteogenic, and adipogenic in vitro differentiation. Differentiation into all three lineages was demonstrated by detection of proteoglycans (Alcian Blue staining), calcium phosphate (Alizarin Red staining), and perinuclear granules with expression of the adipogenic marker PPARγ by immunofluorescence staining. Further isolation of MSCs for more comparative investigations regarding functional effects of the genetic variants is ongoing. Analyses will include transcriptome analyses, assays on physiological cell behaviour, communication potential, and cellular viability. Our innovative method for non-invasive isolation of MSCs provides animal-specific in vitro cell models for research on immunological issues in accordance with the 3R principle. Further studies on the applicability of our results to other livestock species are planned.

In vitro digestion in swine: how close is it to in vivo digestion? – A Systematic Review

M. Pereira[1], M. Catoia[1], M. Blanc[1], I. Bez[1], L. Costa[1]
[1] Pontifícia Universidade Católica do Paraná, Graduate Program in Animal Science, Imaculada Conceição, 1155, 80215-901 Curitiba, Brazil

Digestibility analysis in pigs is traditionally performed through in vivo experiments using indigestible markers, which require animal use, large amounts of feed, and labor. In vitro digestion has emerged as a faster and more cost-effective alternative aligned with the 3R's principles, although discrepancies with in vivo results may occur due to limitations in simulating physiological digestive conditions. Compare the methodologies and results of in vitro and in vivo digestibility studies in pigs through a systematic review, evaluating their reproducibility and reliability. A systematic search was conducted in PubMed, Scopus, and Web of Science without date restrictions, including peer-reviewed articles in English. The review followed the PICo framework, considering pigs as the population, in vitro digestion as the interest, in vivo digestion as the comparison, and the reliability of in vitro methods as the outcome. Based on this, the following search string was constructed: ("pig" OR "swine" OR "sow*" OR "growing pig*" OR "weaned pig*" OR "nursery pig*") AND ("in vitro digestion" OR "in vitro" OR "simulated digestion" OR "enzymatic digestion") AND ("in vivo digestion" OR "in vivo" OR "ileal digestib*" OR "total tract digestib*") AND ("nutrient absorption" OR "nutrient digestib*" OR "digestib* coefficient" OR "apparent digestib*" OR "true digestib*"). After duplicate removal, studies were screened by title, abstract, and full text, including only original articles comparing in vitro and in vivo digestibility in pigs with clearly described methodologies. The search identified 332 records, with 207 non-duplicate articles screened by title and abstract and 59 assessed in full text, resulting in 14 articles (16 experiments) included for data extraction. The methodology of Boisen and Fernández was the most frequently used (42.86%). Simulated digestion conditions varied widely, with stomach phases of 1.5–6 h, intestinal phases of 4–18 h, and temperatures of 39–40 °C. Missing methodological information was common, particularly regarding in vivo trial duration (35.71%), animal production phase (28.57%), and reagents used (21.43%). Regarding in vivo trials, the studies reviewed addressed four different methodologies for determining digestibility, including the use of ileal cannulas, fecal sample collection, ileorectal anastomosis, and ileal digesta collection at the time of slaughter. Based on these procedures, different digestibility parameters were estimated across the studies. Among them, apparent ileal digestibility was the most frequently reported, followed by in vitro digestibility and total tract digestibility. Other parameters, such as ileal + fecal digestibility, fecal digestibility, ileal digestibility, in vitro protein digestion kinetics, digestible energy, and ileal/total tract disappearance, were reported less frequently. In vitro digestion does not fully replicate in vivo digestion in pigs, but it can approximate fecal digestibility under specific conditions. The degree of reliability depends on the chosen protocol and the study objectives, since no universal method applies to all experimental contexts. Thus, in vitro systems should be regarded as complementary tools rather than definitive substitutes for in vivo approaches.

Development of Ovine Hepatic Organoids: A Powerful In Vitro Platform to Reduce the Number of Experimental Animals Used in Metabolism and Nutrition Assays

S. Andrés[1], M. C. González-Montero[2], M. Criado[1], M. Alonso[1], N. Santos[1], D. Gutiérrez-Expósito[1], F. J. Giráldez[1], R. Balaña-Fouce[2,3,4], C. García-Estrada[2,3,4]

The liver plays a central role in coordinating metabolic processes that determine growth, health, and production efficiency in livestock species. In ruminants, hepatic metabolism is uniquely adapted to support glucose homeostasis, lipid partitioning, and nitrogen utilization under conditions imposed by ruminal fermentation, making predictive experimental models essential for studying nutrient-mediated regulation of liver function. However, conventional two-dimensional hepatocyte cultures fail to reproduce the structural organization and functional complexity of native liver tissue, limiting their translational value. In this study, we established and characterized three-dimensional hepatic organoids derived from ovine liver progenitor cells as an advanced in vitro model to investigate ruminant hepatic metabolism. Ovine hepatic organoids were generated from the liver of a male Assaf lamb and characterized by histological and immunofluorescence analyses, followed by transcriptomic profiling using RNA-seq and functional enrichment analysis. Finally, in order to assess the metabolic responsiveness of these hepatic organoids, DL-methionine and/or betaine were supplemented before measuring by RT-qPCR the expression of genes encoding key metabolic enzymes (e.g., CPT1A and PDH1) and ribosomal proteins representative of cellular proliferation (e.g., RPL22L1). According to the results obtained, ovine hepatic organoids formed spherical epithelial structures with defined apical–basal polarity, intact tight junctions, albumin expression, and intracellular glycogen accumulation, indicating preservation of key hepatic features. Comparative transcriptomic analysis revealed extensive overlap between organoids and native liver tissue, with the majority of expressed genes shared between both systems, supporting the conservation of core cellular programs. Nevertheless, differential expression and functional enrichment analyses demonstrated that hepatic organoids exhibit a transcriptional profile biased toward cell proliferation, protein synthesis, and structural remodeling, while genes associated with mature liver metabolic functions, immune responses, and systemic homeostasis were relatively downregulated, which is consistent with a partially differentiated or progenitor-like state. Finally, combined DL-methionine and betaine treatment significantly increased the expression of the CPT1A gene associated with mitochondrial beta-oxidation, indicating a synergistic metabolic response of both compounds and demonstrating the metabolic responsiveness of these ovine hepatic organoids. This work represents the first report of ovine hepatic organoids and establishes a foundation for their use as predictive in vitro platforms to study hepatic metabolism, nutrient–gene interactions, and feed additive strategies in ruminant livestock.

Dynamics of Glutathione Redox Status in Poultry: Impact of Age and Handling Stress

I. Nisamedtinov[1,2], K. Hälvin[2], Y. Le Treut[3], E. Chevaux[3], L. Vigier[3], A. Sacy[3]
[1] Lallemand Inc., Quebec, H1N 2C4 Montreal, Canada, [2] Center of Food and Fermentation Technologies, Akadeemia tee 15A, 12618 Tallin, Estonia, [3] Lallemand SAS, 19 rue des Briquetiers, 31700 Blagnac, France

Commercial poultry production exposes birds to multiple stressors that often triggers oxidative stress, impairing health and performance. Reactive oxygen species (ROS) play a dual role: essential for redox signaling and immune defense at physiological levels, yet harmful when overproduced or when antioxidant defenses are weakened. Glutathione (GSH), the most abundant non-protein thiol, is central to maintaining cellular redox balance, regulating gene expression, and protecting organelles such as mitochondria and nuclei. The GSH/GSSG ratio is a key indicator of redox potential and oxidative status. This work aimed to evaluate GSH redox dynamics in two contexts: (1) growing broilers without any specific challenge and (2) adult laying hens subjected to repeated handling stress (weekly manipulation (n=3) for blood sampling over 2 weeks). In the first study, plasma GSH and GSSG were analyzed in 30 Ross 308 broilers between day 14 and day 32. Results revealed a significant increase ($P<0.01$) in the GSH/GSSG ratio (+37%) over time, despite reductions in both GSH (-6%; $P=0.156$) and GSSG (-30%; $P<0.01$) concentrations, suggesting adaptive antioxidant responses during growth. In the second study, weekly blood sampling of 57 laying hens demonstrated a progressive rise ($P>0.10$) in oxidized glutathione (GSSG), a tendency for a reduction of GSH between d7 and d14 resulting in a non-significant decrease in the GSH/GSSG ratio after one and two weeks. However, mobilization of antioxidant defenses did occur again since laying performance was negatively impacted ($P<0.05$) over 2 weeks. Under stress, GSH acts as a critical redox buffer, detoxifying ROS and supporting GSH-dependent enzymes such as glutathione peroxidase, thereby preserving protein thiols and signaling integrity. Disruption of GSH homeostasis and abnormal protein S-glutathionylation are linked to mitochondrial dysfunction, apoptosis, and impaired immunity, ultimately compromising productivity. These findings highlight the importance of GSH-driven antioxidant strategies to mitigate oxidative stress in poultry systems.

Ex vivo cultivation of primary bovine and porcine fat cells to optimize and refine animal tests

Z. Deng[1], E. Albrecht[1], H. Gu[1], C. Xiao[1], S. Maak[1]
[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany

Adipose tissue development and lipogenesis are critical factors for livestock production efficiency and meat quality. Adipocyte-related investigations typically use in vitro cell lines, such as 3T3-L1 and preadipocytes, which rely heavily on adipogenesis efficiency and neglect substantial discrepancies between differentiated adipocytes and native adipocytes in living organisms. In addition to cell models and different species, different white adipose depots, such as intra- and intermuscular, subcutaneous, perirenal, and mesenteric, also show distinct gene expression profiles and metabolic characteristics. Although in vivo experiments provide physiological relevance, they require extensive animal use and are influenced by systemic variables. Ex vivo primary adipocytes retain native cellular properties and therefore represent a promising intermediate model that may bridge the translational gap and contribute to the refinement and reduction of animal testing. Our study aimed to optimize a culture system for floating primary white adipocytes to facilitate adipocyte maintenance, imaging, and functional analysis. We designed a culture system based on the classical ceiling culture approach to adapt conventional cell culture dishes and multi-well plates. Primary white adipocytes were isolated from bovine and porcine subcutaneous fat for ex vivo culture. Antioxidant supplementation in culture medium, such as 2-Mercaptoethanol, was introduced to enhance cell survival following enzymatic isolation and ex vivo cultivation, a critical step at which adipocytes are particularly vulnerable. Comparative analyses were performed alongside established in vitro models, including 3T3-L1 and preadipocyte-differentiated adipocytes, to evaluate morphology including lipid droplet and live mitochondria staining, gene expression and adipokines secretion, and experimental responsiveness including β-adrenergic agonists and insulin stimuli. Our improved culture protocol enables stable maintenance of ex vivo primary white adipocytes in standard culture formats and supports feasible microscopic imaging and downstream assays. Primary adipocytes, which typically exhibit limited survival after isolation, remained viable for several days under optimized antioxidant-supported cell culture conditions. The larger size and appearance of unilocular lipid droplets were more consistent with in vivo adipocyte physiology than those observed in cell model-derived adipocytes. Notably, the ex vivo adipocytes also keep the ability to dedifferentiate, proliferate, and expand. In conclusion, the optimized ex vivo primary adipocyte cultivation system provides a physiologically relevant and experimentally accessible platform that preserves depot-specific uniqueness. This enables investigation of distinct effects of nutritional or pharmacological substances on adipocytes and offers the potential to develop strategies to control fat metabolism and deposition. Finally, more physiologically similar ex vivo experiments can help to further optimize animal experimental protocols. This work will contribute to the 3R principles by improving in vivo experimental predictability and potentially decreasing the number of animals used in adipocyte-related research.

Targeted sequencing approach for equine microsatellites (Simple Tandem Repeats, STRs) and Single Nucleotide Polymorphisms (SNPs) genotyping to enable transition from STR to SNP-based Equine parentage verification

L. Van De Goor[1], E. Francis[1], S. Dam[1], P. Chemutai[2], B. Kaufman[2]
[1] VHLGenetics, Agro Business Park 100, 6708 PW Wageningen, Netherlands, [2] AgriPlex Genomics, 10969 Cedar Ave., OH 44106 Cleveland, United States

Equine STRs based parentage verification has been extensively used by the horse breeding industry for decades. For this purpose, the International Society for Animal Genetics (ISAG) established a recommended Equine STR panel which currently consists of 12 markers in the core panel. These markers are used by laboratories and studbooks worldwide and enable the exchange of DNA profiles across borders. In 2023, ISAG established a recommended Equine SNP-panel for parentage verification. Many Equine Studbooks and laboratories are considering a transition to equine SNP-based parentage verification. The advantages of an SNP-based approach are that it lends itself to multiplexing thus enables simultaneous genotyping of markers associated with genetic disorders/traits together with breed and parental identification, and by creating a high-density SNP-panel, provides deeper insight into genetic diversity and the development of robust genomic breeding values. This study aims to develop and evaluate a multiplex targeted sequencing panel combining STR and SNP markers for equine parentage verification on the AgriPlex PlexSeq Platform. The panel includes the ISAG STR-markers, ISAG SNP-markers, and a set of markers for genetic disorders and characteristics. Currently the developing panel provides ~90% call rate and the objective is to further elevate this value and to proceed to test the panel on a set of reference samples that will enable to evaluate concordance with STR genotyping, error rates, and parentage exclusion probabilities. This multiplexed targeted sequencing panel is aiming to be an intermediate tool that will facilitate the gradual transition of Equine Studbooks and laboratories from STR-based to SNP-based parentage verification.

Frequencies of known genes of interest in French horses genotyped using a 60K SNP Chip

A. Govignon[1,2], B. Dumont Saint Priest[1], M. Sabbagh[1], S. Danvy[1], A. Ricard[1,2]
[1] Institut Français du Cheval et de l'Equitation, Pole Développement Innovation et Recherche, Les écuries du bois, 61310 Le Pin au Haras, France, [2] Université Paris Saclay, INRAE, AgroParisTech, GABI, 78350 Jouy-En-Josas, France

The Axiom GENOFIL 60K SNP array (60,752 SNPs) was developed by the French equine sector to enable large-scale genomic deployment across French horse populations. This array has been designed to meet multiple objectives, including the analysis of major genes of interest. Given the high diversity of equine breeds in France, objectives differ substantially among Breeding Organizations. Consequently, the relevance of major genes varies across populations, particularly for health- and performance-related traits. Access to genotypes at key loci enables population-level monitoring of allele frequency dynamics and provides a framework for adapting breeding strategies. This study aimed to estimate allele frequencies of major genes of interest across French horse populations using the GENOFIL 60K SNP array. 5,206 horses genotyped with these array were analysed and then divided into seven groups: Thoroughbreds (n=1,250), Trotters (n=397), Arabians (n=419), Sport horses (n=1,520), Ponies (n=1,386), Draft horses (n=148), and Local breeds (n=86). We investigated 84 SNPs associated with 34 major genes of interest, classified into four categories: monogenic (n=16) and polygenic (n=3) health traits, performance traits (n=3) and coat colour traits (n=12). Here we present selected results for major health and performance genes. Polymorphisms were identified in eight genes belonging to the first group. The PLOD1 mutation (Warmblood Fragile Foal Syndrome WFFS) showed variable frequencies across populations, with a moderate proportion of heterozygotes in Sport horses (7.4%). It was also unexpectedly detected in Thoroughbreds (3.6%), while remaining low in Ponies (1.5%) and Arabians (0.2%). As anticipated, MUTYH (Cerebellar Abiotrophy CA) predominantly affected Arabians with 7.6% of heterozygotes, while CLCN1 (Myotonia Congenital MC) was mainly observed in Ponies (2.2% of heterozygotes). In contrast, the GYS1 gene (Polysaccharide Storage Myopathy PSSM) showed a high prevalence in Draft and Local horse populations, with high proportions of heterozygous individuals (30.2% and 45.9%, respectively) and notable levels of homozygotes (4.7% and 12.8%). For DMRT3, as expected, the AA genotype was highly prevalent in Trotters (69.4%), where it characterizes horses with a natural aptitude for trotting, whereas only the CC genotype, associated with galloping ability, was observed in Arabians and Thoroughbreds. The MSTN gene variant determines the preferred racing distance in gallop races. It showed a more balanced distribution of genotypes in Thoroughbreds, with individuals represented across short-, middle- and long-distance performance profiles (25.1%, 45.4% and 29.6%, respectively). The LCORL gene revealed clear size-related patterns across populations. The small-size genotype predominated in Arabians (95.9%), Ponies (84.7%), Thoroughbreds (64.4%) and Local breeds (64.3%), whereas the large-size genotype was nearly fixed in Draft horses (98.0%). In contrast, Sport horses displayed a more even distribution of size genotypes (32.7% large, 53% medium and 14.3% small). With the perspective of transition to SNP-based parentage control, the GENOFIL 60K array will provide genomic data across French horse populations. Breed-level summary statistics generated from these data offer stud-books robust indicators to monitor population dynamics, while individual-level results deliver actionable information to breeders. These results highlight substantial variation in allele frequencies across breeds, reflecting both historical selection and the distribution of inherited disorders.

Genetic diversity in Dutch horse studbooks based on collaborative pedigree analyses

H. P. Doekes[1], M. A. Schoon[1,2], J. G. C. Van Schipstal[1], M. J. Steensma[1], M. F. L. Derks[1], B. J. Ducro[1]
[1] Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6708 BP Wageningen, Netherlands, [2] Wageningen University & Research, Centre for Genetic Resources, the Netherlands, Droevendaalsesteeg 1, 6708 BP Wageningen, Netherlands

Maintaining genetic diversity in domestic horse populations is important to ensure the long-term health, performance, and adaptability of these populations. In the Netherlands, 47 national and international horse breeds are represented, each shaped by its own history of breeding goals, breed popularity, and (inter)national exchange. This study aimed to assess genetic diversity across Dutch horse studbooks using pedigree data and to identify key drivers of inbreeding through a collaborative approach with studbooks. Within the collaborative project 'BehoudenPaard' ("Conserved Horses"), workshops were conducted with studbook representatives to jointly analyse pedigree data from multiple breeds and to build capacity for long-term monitoring of genetic diversity within these populations. These breeds include, among others, Haflinger, Fjord, Dutch miniature, Friesian, Dutch warmblood, Shetland ponies and Welsh and Cob. We first focused on cleaning the pedigrees. Pedigree data were first curated using a custom-developed Streamlit application (https://pedigreecleaner.streamlit.app/) to identify and correct common inconsistencies, including duplicate records, implausible parentage, circular references, and unusually high reproductive output. Subsequently, pedigree analyses were performed to evaluate temporal trends in (1) population size, (2) parental contributions, (3) generation intervals, (4) pedigree completeness, (5) inbreeding and kinship coefficients and their rates of change, (6) founder representation, and (7) population structure in breeds with multiple lines or subpopulations. We recognized several drivers for (too) high inbreeding rates in some of the populations, including a small census size, a (relatively) small breeding population, a "popular sire effect", and the direct replacement of breeding animals by their offspring. Populations varied substantially in these aspects, for example in number of foals born per year ranging from 48 for Groninger, 258 for the Dutch Draught horse to almost 5,000 for Dutch warmblood showjumping horses in 2024. Inbreeding rates also varied across (sub)populations and over time, with historical inbreeding rates reaching in some cases up to 4.5% per generation, and more recent inbreeding rates varying from -0.95% to 2.2% per generation. Here, we will present the variation in genetic diversity metrics across studbooks as well as common threats that negatively affect genetic diversity. We will organise additional workshops on population-specific genetic management strategies, the incorporation of DNA test results into selection schemes, and provide tools for communication of lessons learned to breeders and studbook members to create support and commitment in the long term. These results highlight substantial variation in genetic diversity across Dutch horse studbooks and identify key drivers of inbreeding, including small effective population size and the widespread use of popular sires. The collaborative approach proved effective in increasing awareness and supporting the implementation of sustainable genetic management strategies.

Genomic inbreeding level of the Coldblooded trotter

P. Berglund[1], P. Berg[2], S. Eriksson[1]
[1] Swedish University of Agricultural Sciences, Department of Animal Biosciences, P.O. Box 7023, 750 07 Uppsala, Sweden, [2] Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, P.O. Box 5003, NO-1432 Ås, Norway

The Coldblooded trotter is a breed used for harness racing in Sweden and Norway. It was officially split from the North Swedish horse and the Norwegian Dole horse in the 1960s. Due to extensive exchange of breeding animals between the countries, a joint studbook was established in 2000. Intense selection for racing performance and the use of a limited number of popular stallions have led to increased relatedness among individuals in the population. For horses born in 2021, the inbreeding level based on pedigree information (FPED) has been estimated at 0.084, while the inbreeding rate per generation is 0.012. Previous studies have also reported signs of inbreeding depression in racing performance and fertility. Furthermore, the annual number of foals born has more than halved since the 1990s, raising concerns about loss of genetic diversity. The aim of this study was therefore to estimate the genomic inbreeding level of Coldblooded trotters for strategic management of the genetic resources in this breed. A subset of 81 breeding sires was genotyped with the Affymetrix 670K chip array, where 285,266 SNPs passed quality control. Runs of homozygosity (ROH) were analyzed in PLINK v1.9 with parameter settings based on within-ROH inbreeding developed by Wage et al. (2025). Parameters were set to the following: 50 consecutive homozygous SNPs with the minimum length of ROH set to 500 kb. One missing and zero heterozygote SNPs were allowed per window with a sliding-window threshold of 0.05. The maximum gap between SNPs was set to 1000 kb, and the minimal SNP density within ROH to 1 per 50 kb. A total of 12,346 ROH were retrieved and distributed across the following bin lengths: 0.5-2Mb: 42.4%, 2-4Mb: 27.1%, 4-8Mb: 21.2%, 8-16Mb: 8.3%, and >16Mb: 1.0%. The inbreeding level based on ROH (FROH) ranged from 0.01 to 0.21, with an average inbreeding level of 0.12. The correlation between FROH and FPED was estimated at 0.46. These preliminary results suggest recent inbreeding in the population of Coldblooded trotters. The low correlation found between FROH and FPED indicates that further evaluation is needed to determine the best criteria for managing genetic diversity. With additional genotyped horses, inbreeding depression in racing performance traits and founder-specific inbreeding effects will be studied. The results from this study will aid the breeding organization in developing strategies to maintain the genetic diversity of the Coldblooded trotter.

Size matters – characterisation of candidate causal variants for withers height in horses

P. Reich[1], I. Kilic[1], T. Y. Lin[1], M. Weis[1], J. Tetens[1]
[1] University of Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany

Withers height is a major selection criterion in horse breeding. Beyond its influence on overall appearance, it is associated with health and performance and plays an important role for the classification and market value of horses. Hence, uncovering the genomic basis of withers height is of considerable scientific interest. In a previous study (Reich et al., 2024), a sequence-based GWAS for withers height using imputed data from 2709 German warmblood horses revealed two genome-wide significant association signals on ECA1 and ECA3. Further analysis of the QTL regions resulted in the identification of several candidate causal variants, which were investigated in more detail in the present study to validate their potential impact on withers height and extend the analyses to additional breeds. The three most promising variants – a nonsense mutation in LCORL and a missense mutation in NCAPG in high linkage disequilibrium (ECA3), as well as a missense mutation in the TET1 gene (ECA1) – were genotyped by RFLP or Sanger sequencing in over 250 horses from different breeds. Additionally, genotypes obtained from publicly available sequence data from 317 horses compiled in a previous study (Reich et al., 2022) were considered in the analyses. Genotype data from the included German warmblood horses confirmed allele frequencies close to 0.5 for the LCORL and NCAPG variants, as observed in the previous study using imputed sequence data, and corroborated their very high linkage disequilibrium. The mutant alleles, which were associated with increased withers height, occurred at slightly higher frequencies in other warmblood breeds and Standardbreds, while they were less common in Thoroughbreds and Franches-Montagnes horses (~0.10-0.15). Interestingly, they were very rare or absent in different pony breeds, including German riding ponies, Haflinger and Shetland ponies, as well as Arabians and Quarter Horses. On the other hand, they occurred at very high frequencies (close to 1) in different coldblooded breeds. However, for one light and small draft horse breed (Black Forest horses), the mutant alleles were considerably less common (~0.18) than in the other coldblooded breeds. The TET1 mutant allele occurred at rather low frequencies in warmblood horses and was more prevalent in coldblooded breeds (~0.20-0.25), while it was absent in most other investigated breeds, suggesting a potential impact on the body type of horses. Furthermore, linear regression on over 110 genotyped horses with available phenotype data confirmed the statistically significant association of the LCORL, NCAPG and TET1 variants with withers height both across and within different horse breeds. Likewise, variants in all three of these genes have previously been found to be associated with body size and mass traits in several other species. Taken together, these findings provide strong evidence for the involvement of LCORL, NCAPG and TET1 in the genetic architecture of withers height in horses. The near fixation of the 'small' and 'tall' alleles in pony and coldblooded breeds, respectively, together with the strong association in warmblood horses and consistent findings in other species, highlights the LCORL nonsense mutation as the most promising candidate causal variant. The observed allele frequency patterns across breeds likely reflect historical selection for body size and suggest potential for future genomic selection strategies. However, additional investigations, including gene expression and functional analyses, will help further validate the role of the identified variants in withers height in horses.

Inter- and intra- rater reliability of linear scoring in warmblood breeding

A. Weigt[1], A. Brockmann[3], J. Tetens[2], A. O. Schmitt[1]
[1] Georg-August-University Göttingen, Division for Breeding Informatics, Department of Animal Sciences, Margarethe-von-Wrangell-Weg 7, 37075 Göttingen, Germany, [2] Georg-August-University Göttingen, Division for Functional Breeding, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, [3] Niedersächsisches Landgestüt Celle, Spörckenstraße 10, 29221 Celle, Germany

Reliable phenotypes are a key prerequisite for successful animal breeding programmes and the advancement of genomic applications. However, subjective phenotypic assessment may limit genetic progress and the power of genome-based analyses. In warmblood horses, conformation is commonly assessed using linear scoring. Each score on the linear scoring scale describes one trait within its biological extreme expressions. Despite its important role in the selection process of young breeding horses, the reliability of linear scoring in the context of warmblood breeding has not been sufficiently quantified. In this study, we investigated inter- and intra-rater reliability of linear scoring for conformation traits in German warmbloods. Eleven professional equine breeding experts (e.g. breeding judges) completed an online questionnaire, scoring 17 linear conformation traits in 34 warmblood stallions using side-view images. Participants were asked to repeat the questionnaire after approximately one month. The images originated from the archive of the Hanoverian State Stud in Celle and showed warmblood stallions born between 1929 and 1993. Moreover, these historic images ensured the representation of a wide variety of phenotypes under standardised environmental conditions for all raters. Inter- and intra-rater reliability was assessed using intraclass correlation coefficients (ICCs). Permutation tests were performed for both rounds of the inter-rater analysis and the intra-rater analysis. To determine whether rater scoring was superior to random assignment, all values in the horse × judge matrices were shuffled within each trait separately to eliminate any horse-judge structure while preserving the empirical score distribution. Overall, inter-rater reliability was lower than intra-rater reliability. Inter-rater ICCs ranged from 0.3 to 0.56 across rounds and traits. Intra-rater reliability varied between raters and traits, ranging from poor consistency (ICC = -0.36) to excellent consistency (ICC = 0.90) between rounds. Trait-specific patterns were identified across both types of analysis: the trait Head achieved moderate to good inter- and intra-rater agreement, while traits requiring closer assessment of underlying anatomical structures (e.g. Shoulder Length and Carpal Joints) showed ICCs close to zero. Randomly shuffled horse × judge matrices revealed that most raters outperformed random scoring. Occasionally negative ICC values were observed in the intra-rater analysis indicating that variance between repeated ratings is higher than the phenotypic variance among subjects. Mean linear scores were close to zero, and mean absolute deviations between 0.32 and 0.90 indicated limited use of the -3 to +3 scale. The results of this study show that linear scoring by experts captures non-random phenotypic information. Still, the reliability of assessments, in particular between raters and for more complex traits, is on average low. Enhancing the reliability of linear scoring in warmblood breeding will require revision and standardisation of trait definitions, regular exchange among experts, and extended training of judges to improve consistency and ultimately increase the value of phenotypes for practical breeders or genomic applications.

Genetics of racing performance across different track conditions in Thoroughbred horses in France

S. Harari[1,2], A. Théry[3], G. Fortier[2,4], A. Ricard[1,5]
[1] Université Paris Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78352 Jouy-en-Josas, France, [2] Université Caen Normandie, Normandie Univ, BIOTARGEN UR7450, Esplanade de la Paix, 14000 Caen, France, [3] France Galop, 15 Boulevard de Douaumont, 75017 Paris, France, [4] LABEO, 1 route de Rosel, 14280 Saint Contest, France, [5] Institut Français du Cheval et de l'Equitation, Pôle développement, innovation et recherche, Lieu dit Jumenterie, 61310 Exmes, France

The objective of the study was the estimation of genetic parameters of racing performance and the genetic characterization of the diversity of careers in flat horse racing regarding tracks condition. France Galop provided racing records spanning 2000 to 2024, encompassing 709,381 individual race results from 84,204 Thoroughbred horses in 67,310 flat races on turf track. Performance criteria were the logarithm of earnings (LE) for each race and each horse – either actual or simulated by halving the amount for each successive rank for non-winning horses – and career start status (binary variable: 1 if the horse started at least once, 0 otherwise). Performance was analyzed by track condition based on penetrometer measurements, with four categories: very firm to good, good to soft, soft, very soft to very heavy. Among the horses, 67% raced on very firm to good, 63% on good to soft, 60% on soft, 68% on very soft to very heavy track. The analysis used a multi-trait animal model with LE as linear trait and start status as threshold trait, and including age, stall number (both for LE only), combination of sex, year and country of birth, and inbreeding coefficient (mean of 1.98%, calculated using the whole pedigree with 8.2 generations on average, and divided into 8 classes) as fixed effects, and trainer (n=3,335), animal additive genetic value (180,207 horses in pedigree), and permanent environment as random effects. Analysis was performed by Markov chain Monte Carlo Gibbs sampling using the TM software. Both extreme inbreeding levels had negative effects on start status and LE for all track conditions. Compared with 1.0–1.5% level, very low (<0.5%) and high (>5%) inbreeding resulted in −0.08 to −0.02 and −0.05 to −0.03 phenotypic standard deviation (SD) units for start status, respectively. Similarly, very low and high inbreeding resulted in −0.03 to −0.05 (<0.5%) and −0.07 to −0.11 (>5%) phenotypic SD units for LE, across track conditions. Trainer proportion of variance was 33 to 39% for start status and 8 to 9% for LE. Heritability estimates (standard errors <0.01) ranged from 0.11 to 0.13 for start status and from 0.09 to 0.10 for LE. These results reveal that the effect of the trainer on participation is more important than genetic effect. However, the effect of the trainer on success (LE) is roughly as important as genetic effect. Genetic correlations (standard errors <0.05) among start status were positive and high (0.64 to 0.80) as they were among LE (0.84 to 0.97), revealing that there is no genetic predisposition in participating on a specific track condition. In addition to that, genetic correlations between start status and LE were close to zero, varying between -0.30 and 0.04, revealing that participating on a given track condition and LE on the same or another track condition are genetically close to independent. Main results enabled us to conclude that participation on different track conditions depends more on trainer than on genetics and constitutes a genetically single trait. Furthermore, successes on different track conditions are based on the same genetic foundations. These results suggest a shared genetic architecture of racing performance across track conditions, with participation being primarily influenced by trainers. Similar analyses were made across race category and distance.

Revising selection criteria for endurance performance in Spanish Horses

I. Cervantes[1], K. D. Arias[1], N. Formoso-Rafferty[2], M. Arcos[3], D. I. Perdomo-González[1], J. P. Gutiérrez[1]
[1] Dpto. Producción Animal, Facultad de Veterinaria, Universidad Complutense de Madrid, 28040 Madrid, Spain, [2] Dpto. Producción Agraria, ETSIAAB, Universidad Politécnica de Madrid, 28040 Madrid, Spain, [3] Asociación Española de Criadores de Caballos Árabes, AECCA, 28006 Madrid, Spain

The Spanish Arabian Horse Breeder Association (AECCA) has developed a breeding programme with the aim of improving endurance performance in Spain. There are young horse competitions (YHC) designed specifically for early performance control, where the emphasis is on finishing the race rather than animal's final ranking position. These competitions are for horses aged between four and seven years old. The selection criteria for YHC are based on three traits combined in a genetic index: race time (RT, defined as the time taken to complete the race, minus the time taken to pass the veterinary control); recovery time (REC, defined as the time taken to pass the veterinary control); and placing (P, defined as a categorical trait indicating whether the horse finished the race or not). Genetic and phenotypic trends have recently been analysed, revealing no genetic trend for race time. When analysing phenotypic trends in race time, it appears that there is a limit to how fast horses can become, suggesting that genetic improvement may be slow. Furthermore, it seems that genetic progress is focused more on recovery time than on race time in these young competitions. If the speed is increased through selection, there may be problems in passing the veterinary control, so it may be preferable to maintain the race time. The objective of this study was to evaluate the inclusion of a new selection criteria in the genetic evaluation of endurance horses. We analysed the time per kilometre (TK) and the speed (S). The data set contained 4895 records from YHC. The pedigree included 17254 individuals (59% of which were Arabian horses). To evaluate the two new traits, univariate and multitrait models were run, including TK or S with REC and P. The TK and S models included sex (male, female, gelding), age (five levels), distance as covariate (linear and quadratic) and event (456 levels) as fixed effects, and rider as additional random effect. REC and P were studied using the same model but without including distance. The heritabilities for these new analysed traits were 0.12 (0.02) for TK and 0.09 (0.03) for S. This last heritability was lower than the value found for RT (0.12 (0.02)). Heritabilities for REC and P were 0.27 (0.03) and 0.04 (0.02), respectively. The rider effect variance ratio was 0.09 (0.02) for TK, 0.10 (0.02) for S, 0.09 (0.02) for REC, but was not different from zero for P. Regarding genetic correlations with other traits, it was shown that none of the trait pairs had a genetic correlation that was different from zero. It seems that either TK or S could replace RT. Speed could be important in higher level races where the horses are well trained and there is no speed limit. This could improve the genetic trend for the time taken to complete the race in future, but studies of older horses in higher level competitions are also needed.

Early genomic selection for fertility in Pura Raza Española horses using array equigene

H. Srihi[1], M. Valera[2], C. Ziadi[3], N. Laseca[2], A. Rodríguez Sainz De Los Terreros[1], P. Azor[1], I. González[1], A. Gil-Gálvez[1], D. Perdomo-González[4], J. Poyato-Bonilla[1], A. Encina[1], S. Demyda-Peyrás[3], A. Molina[3]

Utrera Km 1, 41013 Sevilla, Spain, [3] University of Cordoba, Dpt. of Genetics, Edificio C5 Gregor Mendel. Campus de Rabanales, 14014 Córdoba, Spain, [4] Universidad Complutense de Madrid, Dpt. of Animal Production, Avda. de Séneca, 2. Ciudad Universitaria, 28040 Madrid, Spain

Fertility is economically critical in horse breeding, yet genetic improvement remains challenging due to low heritability and late phenotypic expression. Traditional evaluation requires waiting 4-6 years until first foaling, followed by additional years to assess lifetime performance, creating generation intervals of approximately 10 years. The objective of this study was to evaluate whether genomic information enables early identification of animals with different reproductive potential before phenotypes become available. We analyzed 4,750 Pura Raza Española horses genotyped with the Axiom EQUIGENE 90K SNP array (81,543 SNPs post-quality control), with reproductive phenotypes from 47,502 breeding records for seven fertility traits: Reproductive Efficiency, Age at First Foaling, Age at Last Foaling, Total Foaling Number, Average Interval Between Foalings, Interval between First and Second Foaling, and Productive Life. Heritability estimates ranged from 0.07 (Interval between First and Second Foaling) to 0.35 (Age at Last Foaling). Genomic breeding values were estimated using single-step genomic methodology integrating pedigree and marker information, providing genetic predictions for all animals including young individuals without phenotypes. Animals were grouped according to their genomic breeding values to evaluate whether early genomic predictions correspond to subsequent reproductive performance. Young animals in the top group for genomic merit (highest 20%) were compared to those in the bottom group (lowest 20%) to examine differences in actual fertility outcomes when phenotypes later became available. Results showed that genomic predictions successfully distinguished between animals with different reproductive potential. Animals with high genomic merit at weaning showed better subsequent fertility performance, including earlier age at first foaling, higher total foaling numbers, and better reproductive efficiency compared to animals with low genomic merit. The ability to rank animals by reproductive potential at weaning (6-8 months of age), years before traditional evaluation becomes possible (5-6 years), enables earlier selection decisions. Breeders can identify superior breeding prospects and make culling decisions for animals with poor genetic merit at weaning rather than investing resources in raising them to breeding age. Implementation of genomic selection at weaning instead of waiting for phenotypic maturity could reduce generation intervals from approximately 10 years to 6-7 years, representing a 35-40% reduction and proportional acceleration in genetic progress for fertility traits.

Genomic breeding values for sport performance in German riding horses

M. Wobbe[1], H. Alkhoder[1], K. F. Stock[1]
[1] IT Solutions for Animal Production (vit), Heinrich-Schroeder-Weg 1, 27283 Verden, Germany

National genetic evaluation for sport performance in riding horses in Germany is carried out annually on behalf of the German Equestrian Federation (FN). Since 2019, the system includes the traits highest level achieved in dressage (HLD) and show jumping (HLJ), proposed as target traits for future routine genomic evaluation. The aim of this study was to develop the prototype of single-step genomic evaluation for HLD and HLJ following the approach used for the new routine genomic evaluation for linear conformation, movement and jumping traits. The national genetic evaluation considers starts in dressage and show jumping competitions and is based on all national competition data and additionally international competition data of German horses. For each horse, HLD and HLJ are determined under the precondition of at least three starts in the respective discipline. For this study, HLD and HLJ data were made available by the FN for 348,471 horses registered by one of the German studbooks for riding horses belonging to genomic consortium. In the genomic evaluation system, this phenotypic data was used together with genome-wide SNP genotypic data (80K / Equine80select) and pedigree data over four ancestral generations. This resulted in a total system size of 818,340 horses analyzed with the single-step method using Mix99 software and the same model as in the national genetic evaluation. The following fixed effects were included: sex (mare, stallion or gelding), year in which HLD or HLJ was first achieved (calendar year, 1996 – 2025), age of horse at last competition start (4-5, individual years from 6 to 14, 15 and older). Estimated genomic breeding values (gEBV) were standardized to a mean of 100 and genetic standard deviation of 20, with basis defined by the 6- to 9-year-old horses with phenotype (N = 21,958 horses born 2017 – 2019).Results from the national genetic evaluation (EBV) were available for published stallions and active broodmares of the studbooks from the genomic consortium and were used to determine Pearson correlation coefficients between gEBV and EBV. High correlations of 0.97 for HLD and 0.96 for HLJ were found, indicating no major re-ranking. With a growing number of horses with sport-related phenotypic information and genotypic data, reliability of gEBV is expected to increase and improve discrimination between individual horses' genetic potential for performance in dressage and show jumping. Currently, it is mainly older stallions fulfilling publication criteria for EBV for HLD and HLJ, and EBV for mares often remain vague. In the future, sport horse breeders in Germany will increasingly benefit from early implementation of routine SNP genotyping giving early access to gEBVs for a growing range of traits. Calibration and validation of the presented prototype will prepare for complementing the genomic support of selection and mating decisions of sport horses in Germany.

Discipline specialization and its impact on genetic trends followed by genomic breeding values for conformation, gaits and jumping in sport horses in Germany

K. F. Stock[1], M. Wobbe[1], C. Schmidtmann[1]
[1] IT Solutions for Animal Production (vit), Heinrich-Schroeder-Weg 1, 27283 Verden, Germany

Within the framework of breeding programs of the studbooks, sport horse breeding is shaped by expectations of riders and concepts of breeders. Studies have shown that the roles of the two main disciplines of riding sport, dressage and show jumping may have changed over time, with specialization understood as key to performance on the highest level in equestrian sport. The aim of this study was to quantify the extent of specialization and to evaluate its impact on analyses of genetic trends in sport horses in Germany. Information on the numbers of progeny with competition records in dressage and show jumping, available for 5,254 approved sires, was used to distinguish between specialized (at least 70 % of all competing progeny in either dressage, D, or show jumping, J) and allround stallions (A). This stallion classification was applied to sires and maternal grandsires of horses with genomic breeding values from the new routine single-step genomic evaluation for linear conformation, movement and jumping traits. This system uses results of linear descriptions from all major studbooks of riding horses in Germany (phenotypes from 2012 to 2025; > 81,000 horses) together with the genome-wide SNP genotypic data made available for their breeding programs (mostly 80K / Equine80select array; > 131,000 horses) plus pedigree information of four ancestral generations. For further analyses, genomic breeding values (gEBV) for all 28 conformation, 19 movement and 12 jumping traits of 315,266 horses born 1985 and later were considered. Stallions category data for sire and maternal grandsire was complete for 196,201 of these horses and indicated an increasing proportion of horses descending from D sire and D maternal grandsire or J sire and J maternal grandsire (> 80 % for birth years 2010 and later). More specialized training and competing in recent than former years has likely contributed to the observed relative decrease of horses classified as A (A sire and A maternal grandsire or combination of different categories). Genetic trends were determined by calculating of mean gEBV per birth year for either all horses (N = 315,266) or separately for D horses (N = 68,527) and J horses (N = 77,801). Results for overall genetic trends revealed mostly minor changes for conformation traits, whereas increases in performance-related traits were more obvious for movement than for jumping (increases of mean gEBV by around 15 vs. 5 points since 1985). Considering specialization, we found obvious discipline-specific patterns of genetic trends in the specialized horses: strongly positive trend for movement (+ 25 points or more) and negative trend for jumping in D horses, slightly positive trend for movement and strongly positive trend for jumping (up to +20 points) in J horses. Genetic trends for some of the conformation traits indicated differences in development in relation to discipline-specialization. This study has illustrated that analyses of genetic trends for the whole sport horse population or within a non-specialized studbook may lead to underestimation in genetic progress in the discipline-specific target traits and involves the risk of missing possibly unfavorable developments in functionality aspects.

Parentage Verification in Pura Raza Española Horses: Transition from Microsatellites to SNP-Based Genotyping Using the EQUIGENE 90K Array

H. Srihi[1], M. Valera[2], N. Laseca[2], A. Rodríguez Sainz De Los Terreros[1], P. Azor[1], I. González[1], A. Gil-Gálvez[1], J. Poyato-Bonilla[1], A. Encina[1], S. Demyda-Peyrás[3], A. Molina[3]

[1] Royal Purebred Spanish Horse Breeders' Association (ANCCE), Cortijo de Cuarto, 41014 Sevilla, Spain, [2] University of Seville, Dpt. of Agronomy, Ctr. Utrera Km 1, 41013 Sevilla, Spain, [3] University of Cordoba, Dpt. of Genetics, Edificio C5 Gregor Mendel. Campus de Rabanales, 14014 Córdoba, Spain

Maintaining studbook integrity through accurate parentage verification is fundamental to horse breeding programs. The Pura Raza Española (PRE), with over 290,000 registered horses worldwide, has relied on microsatellite-based parentage testing for over 20 years. However, the integration of genomic selection requires SNP genotyping, creating an opportunity to transition parentage verification from microsatellites to SNP-based platforms. ANCCE developed the custom EQUIGENE 90K array incorporating 90,926 SNPs, including the complete ISAG recommended parentage panel (859 SNPs), to serve multiple purposes: disease detection, evaluation of economically important traits, performance characteristics, and genomic selection. The objectives were to validate SNP-based parentage verification accuracy in challenging scenarios with closely related candidate parents, and to implement imputation from ANCCE's 19-microsatellite panel to facilitate connection of newborn foals with their parents using historical parentage records. Parentage verification was validated using 1,235 parent-offspring trios, including animals with close familial relationships. The ISAG compatible SNP panel demonstrated assignment accuracy exceeding 99.5% . The inclusion of challenging scenarios with closely related candidate parents demonstrated the superior power of SNP-based verification. In cases where full siblings exhibited up to 98.6% SNP compatibility and half-siblings showed 94.2–97.8% compatibility, the SNP panel maintained superior discrimination power versus traditional microsatellite approaches. These challenging scenarios provided evidence that when dealing with consanguinity, maintaining stringent thresholds near 1% incompatibility is essential for reliable parentage assignment. To enable integration of over 20 years of historical parentage records and facilitate verification of newborn foals using parents previously genotyped with microsatellites, imputation from the 19-microsatellite panel to equivalent SNP markers was implemented. This imputation strategy allows the connection of new generations genotyped with the EQUIGENE array to historical pedigree data, maintaining pedigree continuity during the transition from microsatellite to SNP-based platforms. In conclusion, the EQUIGENE 90K array successfully integrates the ISAG parentage panel, providing highly accurate verification that surpasses traditional methods, particularly in challenging scenarios with closely related individuals. The implementation of microsatellite-to-SNP imputation enables integration of over 20 years of verified parentage data, allowing connection of newborn foals to parents in the historical database.

Population structure and inbreeding in the Old Kladruber horse

B. Hofmanova[1], H. Vostra Vydrova[1], L. Vostry[2]
[1] Czech University of Life Sciences Prague, Ethology and Companion Animals Science, Kamycka 129, 165 00 Praha, Czech Republic, [2] Czech University of Life Sciences Prague, Genetics and Breeding, Kamycka 129, 165 00 Praha, Czech Republic

The Old Kladruber horse is a unique Czech autochthonous breed with pedigree records dating back to the eighteenth century. This population is closed, with a limited number of individuals, and is included in genetic resources. Therefore, it requires continuous monitoring of genetic diversity. In this context, the availability of long-term, well-maintained breeding records represents a considerable advantage. The aim of this study was to assess genetic diversity using genealogical and molecular (SNPs) data. For this purpose, a total of 9,940 pedigree records of animals born between 1729 and 2023 were utilized. The reference population comprised active animals (stallions and mares) born between 2000 and 2023 (n = 516). Pedigree analyses were performed using CFC and Retriever software. At least 98 % of animals in the reference population had five or more generations fully documented, with the average equivalent complete generations ranging from 10.73 to 12.66. The top 10 ancestors were identified, and the first four most important ancestors accounted for 31 % of the total genetic variability in the reference population. The average generation interval was long, at 12.43 years. All individuals included in the reference population were inbred. The average inbreeding coefficient showed a gradual, continuous year-to-year increase, reaching a maximum of 12.05 % in animals born in 2017. The average inbreeding rate was 1.11 %, and the corresponding effective population size equals 45. These parameters are slightly above (ΔF), respectively below (Ne) the FAO-recommended limits for the conservation of genetic diversity. These findings were supported by a genomic analysis of 420 individuals using 53,420 SNPs, which revealed an average genomic inbreeding coefficient of 14 % and an effective population size of 53 individuals. Overall, the results provide important insights into the current level of genetic diversity of the Old Kladruber horse and may support future conservation and breeding strategies for this unique breed. This work was supported by the GACR 24-14325L project.

Interactions between microplastics and the gastrointestinal ecosystem of livestock: integrating experimental evidence and emerging concepts

D. Brugger[1], J. Eichinger[2]
[1] University of Helsinki, Department of Agricultural Sciences, Koetilantie 5, 00790 Helsinki, Finland, [2] University of Bern, Vetsuisse-Faculty, Bremgartenstrasse 109, 3001 Bern, Switzerland

Microplastics (MP) have recently emerged as a potential contaminant in livestock production systems through feed, water, and environmental exposure. Despite increasing attention in environmental sciences, the biological relevance of MP for gastrointestinal physiology and microbiology in livestock remains poorly understood. The aim of this presentation is to integrate current conceptual understanding of MP–host interactions in the gastrointestinal tract with recent experimental findings from controlled gastrointestinal simulation. Recent in vitro experiments employing rumen simulation systems assessed the effects of various MP types, which were combinations of different polymer species (polylactide, polyhydroxybutyrate, high-density polyethylene (HDPE), polyvinyl chloride, polyproylene), particle-size classes (<125 µm; 125-500 µm), and dosages (0-70 mg/incubation cylinder) of MP on ruminal fermentation and microbial function. Across all MP types overall fermentation performance decreased, and metaproteomic analyses indicated a functional shift towards stress and repair responses within the microbial ecosystem accompanied with declines in metabolic categories linked to carbohydrate and amino acid metabolism. In parallel, ruminal dry matter disappearance increased dose-dependently over the range of MP inclusion, which is consistent with interactions of MP with ruminal degradation processes and suggests that even chemically inert polymers such as high-density polyethylene (HDPE) may undergo measurable alteration under ruminal conditions. Collectively, these findings support the hypothesis that MPs may act less as classical toxicants and more as physical and chemical interfaces within the digestive ecosystem. A broader synthesis of the emerging literature indicates that the gastrointestinal tract represents a complex interaction network where MPs may influence microbial communities, digestive processes, and host–microbe interactions through several mechanisms. Proposed pathways include particle–microbe attachment processes, adsorption and release of organic compounds on polymer surfaces, and physical interactions with mucus and epithelial barriers. In livestock, these interactions may be further modified by the highly dynamic physicochemical environment of digestive compartments such as the rumen. Taken together, current evidence suggests that the biological significance of MPs in livestock is unlikely to be explained solely by toxicological paradigms derived from aquatic models. Instead, a systems-oriented perspective focusing on digestive microbiology and host–microbe interactions appears more appropriate. Future research should therefore combine controlled experimental approaches with microbiome and functional analyses to better understand whether MP exposure can affect digestive ecosystem stability, nutrient utilization, or animal health. This overview highlights how integrating experimental evidence with conceptual frameworks can help refine hypotheses and guide future research on MPs in livestock production systems.

Interaction of polyethylene terephthalate microplastics within the rumen environment

S. Tassone[1], V. Balestra[1], S. Barbera[2], R. Issaoui[3], H. Kaihara[1], A. Zanola[1], K. Abid[1]
[1] University of Turin, Agricultural, Forest and Food Sciences, Largo P. Braccini 2, 10095 Grugliasco, Italy, [2] ZeroMps s.r.l., Via Adige 9, 10098 Rivoli, Italy, [3] University of La Rioja, Area of Biochemistry and Molecular Biology, Avenida de la Paz 93, 26006 Logrono, Spain

Microplastics (MPs) are increasingly detected in livestock feeds, drinking water, animal tissues, feces, and animal products, raising concerns about their potential interaction with ruminal physiology. The rumen represents a primary site where MPs may simultaneously affect nutrient degradation and undergo transformation. This study aimed to evaluate the effects of polyethylene terephthalate (PET) MPs on ruminal degradability and fermentation parameters of different feed matrices (mixed hay, concentrate, and total mixed ration [TMR]), and to determine the extent of PET MPs degradation under simulated ruminal conditions. Mixed hay degradability and digestibility were evaluated using a three-step ruminal–gastrointestinal method (Ankom DaisyII incubator). PET MPs were added at 0, 5, 10, and 15 g/L of inoculum. Three different hays were tested in triplicate across three experimental runs (n = 108). PET MPs significantly reduced crude protein degradability in the ruminal phase (−9% and −16% at medium and highest doses, respectively) and decreased neutral detergent fiber degradability by up to 13%. In the intestinal phase, crude protein digestibility of rumen-undegraded residues decreased by 8% at the lowest PET level, indicating impaired protein and fiber utilization in forage-based diets. In a batch rumen fermentation model, concentrate feed degradability and fermentation parameters were evaluated with PET MPs included at 0, 0.6, 1.2, and 1.8% of feed dry matter (96 h incubation; n = 36). Results showed that PET MPs altered fermentation kinetics by increasing asymptotic gas production (6%) and average fermentation rate (13%), while shortening lag time (from 0.77 h to 0.26 h at the highest level). Despite increased gas output, dry matter and organic matter degradability decreased (−4.1% and −4.6%, respectively). Ammonia-nitrogen concentration increased (+6.7%), rumen protozoa declined linearly, and microbial efficiency was reduced, indicating disrupted fermentation balance and a potential decoupling between gas production and effective substrate degradation. TMR degradability was evaluated in the Ankom DaisyII incubator after 48 h of incubation with PET MPs of three particle-size fractions (25–150, 150–300, and >300 µm). The experiment included replicated treatments across multiple runs (n = 192). PET MPs reduced dry matter degradability (−1.9%) and fiber fractions degradability; however, the inhibitory effect was not particle-size dependent. In vitro ruminal degradation of PET MPs was evaluated using the Ankom DaisyII incubator with TMR as substrate. PET MP degradability was quantified gravimetrically as percentage weight loss. In the time-course experiment (24, 48, and 72 h; n = 54), PET exhibited progressive and significant degradation (0.50 ± 0.070%, 0.73 ± 0.057%, and 0.96 ± 0.082%, respectively; $p < 0.0001$). In a second experiment evaluating PET MPs of different particle sizes (25–150 µm, 150–300 µm, and >300 µm; n = 90), degradation after 48 h was particle-size dependent: small and medium particles reached values up to 1.50%, whereas larger particles showed lower weight loss (0.51%). Overall, PET MP degradation remained below 1.5% within typical ruminal retention times, indicating limited but measurable ruminal biodegradation, particularly for smaller particles. In conclusion, PET MPs negatively affect nutrient degradability in forage, concentrate, and TMR diets, while undergoing minimal degradation in the rumen environment.

Growth, jejunal integrity, and physiology of pigs are maintained with diets containing microplastics

P. Lin[1,2], L. Pinotti[2], G. Bee[1], M. Tretola[1]
[1] Agroscope, Swine research group, La Tioleyre 4, 1725 Posieux, Switzerland, [2] University of Milan, Department of Veterinary Medicine and Animal Sciences, Via Dell'Università 6, 26900 Milan, Italy

Microplastics (MP) are ubiquitous pollutants that have been found also in feed and feed ingredients for livestock, potentially affecting animal health and physiology. Alternative feed ingredients like former food products (FFPs), were selected to study this subject in a realistic scenario as the presence of MPs in FFPs has been reported while still within legal allowance. Two FFPs (analyzed in triplicate, 20 g each) were analyzed using microscopy and Fourier-transform infrared spectroscopy to identify plastic packaging fragments. Eight plastic fragments (average size = 6.7 mm) were detected in FFP1 and two (average size = 3.4 mm) in FFP2. Given these findings and the potential for macro- and mesoplastics to further break down into MPs during digestion, an in vivo trial was conducted using pigs as a model to examine the effects of feed-derived MPs on animal performance, apparent total tract digestibility (ATTD), and gut health. In total, 36 Swiss Large White male castrated pigs (22.38 ± 1.70 kg body weight) were assigned to one of the three growing and finishing diets (1) a standard diet containing no FFPs (ST); (2) a diet in which 30% of conventional feedstuffs were replaced by FFP1; and (3) a diet in which 30% of conventional feedstuffs were replaced by FFP2. For each pig, average feed intake, average daily gain, feed efficiency and ATTD were monitored. A mass spectrometry-based untargeted metabolomics investigation was performed on plasma samples from all the animals. Twenty-four fecal samples were collected from the rectal ampulla to analyze fecal volatile fatty acids level and microbiota population using high-performance liquid chromatography and next-generation sequencing, respectively. Fecal MP content was also quantified. Organic matter was digested with 30% H2O2, and a saturated NaCl solution (D = 1.2 g/cm3) was added to separate target MPs (polyethylene and polypropylene) into the supernatant. Two jejunal samples from each pig (≥ 7 pigs per treatment) were collected and mounted in Ussing chambers to evaluate the trans-epithelial resistance (TEER) to assess jejunal epithelial integrity. All data were analyzed by analysis of variance using linear mixed-effects regression models in R v4.0.3, except that the packages phyloseq, vegan, microbiome, and microbiomeutilities were used for microbiota data analysis. Both FFPs decreased fiber ATTD in the finishing phase but FFP1 increased the energy and crude protein ATTD in the growing period. The type of FFPs and the related MP contamination level did not affect ($P > 0.05$) pig's growth traits, plasma metabolome, TEER, and fecal microbiota abundance or biodiversity (Shannon index) and fecal volatile fatty production. No MP was observed in the fecal samples by using the selected method. This indicates that the contamination level of plastics in FFPs, does not cause immediate observable negative effects on pig's performance and gut health. Further studies with controlled feed spiking at different MP concentration are warranted to investigate whether feed-sourced MPs can remain in carcass and meat and alter their quality. Additionally, other more accurate MP extraction methods for complex organic matrices like feces has to be tested.

Analysis of microplastics in black soldier fly larvae exposed to packaging materials

L. Tromp[1], B. Hedemann[1], N. Dam[1], N. Meijer[1]
[1] Wageningen Food Safety Research, Akkermaalsbos 2, 6708WB Wageningen, Netherlands

Reared insects are increasingly seen as an alternative protein source. Black soldier fly larvae (BSFL, Hermetia illucens (L.) Diperera: Stratiomyidae) have a high potential for circular use in the feed chain, because they can be reared on a variety of materials unsuitable for 'conventional' livestock. One such material includes former foodstuffs (FFS) with elevated levels of packaging materials. At this time, remnants of packaging are prohibited in feed, but complete removal not feasible. We hypothesized that BSFL would not be affected by the presence of packaging materials in feed, and that the resulting larval biomass would be safe as a protein source for feeding to other animals. The aims of this project are to gather more data on the safety of rearing BSFL on feed with (biodegradable) plastics, to enable risk assessment by the competent authorities. To properly assess the possible hazards arising from rearing insects on FFS containing packaging materials, physical (microplastics) and chemical (contaminants) hazards are researched. Effects of these materials on the assayed insects (e.g., yield and survival) will also be monitored, as well as possible (bio)degradation of the plastics by the insects. Included in this presentation are the first results from microscopy-based analyses of BSFL that had been exposed to different forms of plastic packaging materials in the substrate. In order to detect possible (micro)plastics in the larvae, a tailored digestion method was employed to remove organic biomass while not affecting the plastic integrity. Scanning microscopy allowed to generate large-scale images of slides, using polarization-based optical filtering to contrast remaining biomass with the microplastics.

Transcriptomic profiling of aflatoxin B1 exposed and medicinal herb supplemented pig liver

A. A. Nalpadan[1], H. Reyer[1], M. Oster[1], N. Trakooljul[1], S. Ponsuksili[1], W. Kozera[2], K. Karpiesiuk[2], M. Pierzchała[3], A. Lepczyński[4], B. Ślaska[5], C. S. Pareek[6], K. Wimmers[1,7]

[1] Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] University of Warmia and Mazury in Olsztyn, Department of Pig Breeding, Faculty of Animal Bio-Engineering, Michała Oczapowskiego 5, 10-959 Olsztyn, Poland, [3] Institute of Genetics and Animal Biotechnology of the Polish Academy of Sciences, Department of Genomics and Biodiversity, 36A Postępu St., 05-552 Jastrzębiec, Poland, [4] West Pomeranian University of Technology, Department of Physiology, Cytobiology and Proteomics, Klemensa Janickiego 29, 71-270 Szczecin, Poland, [5] University of Life Sciences in Lublin, Faculty of Animal Sciences and Bioeconomy, 13 Akademicka Street, 20-950 Lublin, Poland, [6] Nicolaus Copernicus University, Faculty of Biological and Veterinary Sciences, ul.Szosa Bydgoska 13, 87-100 Toruń, Poland, [7] University of Rostock, Faculty of Agricultural, Civil and Environmental Engineering, Justus-von-Liebig-Weg 6, 18059 Rostock, Germany

Aflatoxin B1 (AFB1) is a toxic secondary metabolite produced by Aspergillus fungi. Dietary exposure of AFB1 strongly induces adverse effects in farm animals. EU feed legislation sets maximum AFB1 at 20 µg/kg in pig compound feed (piglets: 5 µg/kg; 12% moisture). With rising climate-driven contamination risk and non-exhaustive monitoring, especially for on-farm feed, contaminated lots can still enter rations and exceed legal limits. Chronic exposure of AFB1 in feed can lead to critical physiological and pathological consequences in animals, including reduced growth rates, reproductive issues, immunosuppression, and gut barrier dysfunctions. Since the complete eradication of AFB1 from feedstock through physical and chemical methods is ineffective, several natural additives with anti-toxic properties have been widely investigated as potential AFB1 mitigation strategies. Extracts from medicinal herbs and their constituent bioactive compounds have demonstrated significant hepatoprotective activity, aiding in the restoration of liver integrity. Accordingly, a nutritional experiment was performed incorporating AFB1 (120 µg/kg BW) exposure via feed; kalmegh (Andrographis paniculata: 30 mg/kg BW), milk thistle (Silybum marianum: 90 mg/kg BW) and turmeric (Curcuma longa: 90 mg/kg BW) supplementation (BW: body weight) in distinct pig groups, followed by RNA sequencing of liver tissue (n = 44). Serum biochemical parameters associated with liver health were analyzed to compliment the gene expression data. The analysis of differentially expressed genes (DEG) in AFB1-exposed animals revealed transcriptomic modulations in genes like CYP2A19, CYP1A2, GSS, GPT2, and PCK1 related to AFB1 primary biotransformation, mounting of toxic responses and reduced energy derivation. Alternatively, with medicinal herbs, a positive adaptive regulation of respective genes CYP27A1, ACSS2, and HAMP was observed in terms of metabolic activation, energy and iron homeostasis. Furthermore, AFB1 exposure in pigs resulted in modulated serum hepatic parameters suggesting an onset of aflatoxicosis. Conversely, in medicinal herb supplemented animals, the absence of significant differences in biochemical parameters levels indicated an unaffected healthy liver function. These findings provide a foundation for delineating the specific molecular mechanisms related to both AFB1 exposure and medicinal herb supplementation and account for possible nutritional strategies in future aimed at mitigating AFB1 toxicity in animals using natural additives. This project has received funding from the Deutsche Forschungsgemeinschaft (DFG) Project No. 504983453 (WI 1754/18) and Narodowe Centrum Nauki (NCN) Project No. UMO-2021/43/I/NZ9/02612.

Microplastics in animal-based food products: occurrence, contamination pathways, and analytical challenges

E. Visentin[1], G. Niero[1], M. De Marchi[1]
[1] University of Padova, Department of Agronomy, Food, Natural resources, Animals and Environment, Viale dell'Università, 16, 35020 Legnaro (PD), Italy

Microplastics are plastic particles smaller than 5 mm, generated either through the intentional production of small-size plastics or through the fragmentation of larger plastic items. Their persistence and widespread environmental distribution have raised increasing concern regarding their entry into the food chain, including livestock production systems. While marine ecosystems have been extensively investigated, there is still a lack of studies investigating the occurrence of microplastics in animal-based food products. The aim of this contribution is to provide a comprehensive overview of current knowledge on microplastic contamination in animal-based foods, linking environmental exposure, livestock management practices, and food processing dynamics along the production chain. In farm animals, ingestion through contaminated feed, water, soil, and airborne particles represents the primary exposure route. Although the extent of biological transfer from feed to animal tissues remains under investigation, organs involved in product formation, such as the mammary gland and reproductive system, represent potential interfaces for particle translocation. In addition, contamination may occur during milking, slaughtering, processing, packaging and storage, reflecting the complexity of modern production systems. To date, major uncertainties persist regarding analytical harmonization, particle characterization, contamination sources, and quantitative exposure assessment. In particular, the lack of standardized analytical protocols hampers by far cross-study interpretation. Notably, specific regulatory thresholds for microplastics in food are currently lacking, and risk assessment frameworks remain constrained by limited clinical data at both animal and human level. By integrating evidence from different animal-based matrices and identifying critical points along the production chain, this work highlights priority research needs and methodological challenges. Strengthening harmonized analytical approaches and refining exposure assessment models will be essential to support the development of science-based regulation framework and mitigation strategies aimed at reducing microplastics diffusion and circulation.

LC–MS/MS determination of pesticide and antibiotic residues in milk: effects of thermal processing and composition

M. F. Puigvert[1,2], L. Grille[1], M. Irazoqui[2], T. López-Pedemonte[3], S. Jorcín[3], L. Pareja[2]
[1] Universidad de la República, Ciencias Veterinarias y Agrarias, Ruta 3 km 363, 60000 Paysandú, Uruguay, [2] Universidad de la República, Departamento de Química del Litoral, Ruta 3 km 363, 60000 Paysandú, Uruguay, [3] Universidad Tecnológica del Uruguay, Alimentos, Cno. Alejandro Malcom S/N (ex destilería Rosario), 70200 Colonia, Uruguay

In pasture-based dairy systems, cattle may be exposed to chemical residues from both environmental sources, such as pesticides used in crop production, and the use of veterinary drugs, posing food safety concerns. Dairy processing treatments such as pasteurization and ultra-high temperature (UHT) may influence residue stability, distribution and concentration within the milk matrix, making their behavior relevant for risk assessment and regulatory monitoring. This study investigated whether thermal processing modifies the fate of pesticide and antibiotic residues through compound-specific degradation and partitioning within the milk matrix. A multi-residue LC–MS/MS method was developed and validated to assess the impact of thermal processing and milk composition on pesticide and antibiotic residues in milk following SANTE/11312/2021 guidelines. A solid–liquid extraction procedure was optimized for the determination of selected pesticides and veterinary drugs relevant to the Uruguayan production context using LC–MS/MS. Method validation included evaluation of trueness (% recovery), precision (% RSD), selectivity, limits of quantification, linearity, robustness and matrix effects. Acceptance criteria were recoveries between 70–120 %, RSD ≤20 % and linearity with back-calculated concentrations ≤20 %. To evaluate residue behavior during dairy processing, raw milk previously confirmed as residue-free was fortified with selected pesticides and veterinary drugs at 50 µg/kg and subjected to thermal treatments in a laboratory-scale fluid milk processing line. Thermal treatments included pasteurization (72 °C for 15 s; 3 L/h) and UHT processing (142 °C for 4 s; 20 L/h). Representative samples (n = 3) were collected at different stages of processing to monitor changes in residue concentrations. Data were analyzed using analysis of variance (ANOVA) followed by Tukey's test ($p < 0.05$). Results showed the relevance of the milk lipid fraction on contaminant distribution. Highly lipophilic compounds such as abamectin, carbaryl, diazinon and fluazuron showed a clear tendency to partition into the cream fraction, reaching concentrations of 40–210 µg/kg, whereas considerably lower levels were detected in skim milk (2–49 µg/kg). In contrast, other analytes exhibited a more homogeneous distribution between lipid and aqueous phases. For both thermal treatments, residue concentrations of compounds such as fluazuron and fipronil remained stable ($p > 0.05$), consistent with previous reports by Rose et al. (2017). Additionally, milk standardization at different fat contents (2.6% and 3.0%) resulted in a greater decrease in overall contaminant concentrations in samples with lower fat content. These findings demonstrate that milk composition plays a key role in determining the fate of pesticide and antibiotic residues during dairy processing. The proposed analytical approach provides a robust tool for studying contaminant behavior in dairy systems and contributes to improving residue monitoring and food safety management in dairy production chains.

Replacement of hexane-defatted oilseed meals with 2-methyloxolane-defatted oilseed meals in dairy cows' diet: Effects on dairy performance and nitrogen utilisation

V. Menoury[1], A. Ferlay[1], D. Andueza[1], G. Cantalapiedra-Hijar[1], J. Engel[2], E. Jorge-Smeding[1], S. Lemosquet[3], P. Nozière[1]

[1] Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Route de Theix, 63122 Saint-Genès-Champanelle, France, [2] Mathematical & Statistical Methods group (Biometris), Wageningen University & Research, , 6700AA Wageningen, Netherlands, [3] PEGASE, INRAE, Institut Agro, , 35590 Saint-Gilles, France

Hexane (HEX) is used to defat oilseed meals fed to livestock. However, HEX is sourced from petroleum and its main compound, n-hexane, is considered a substance of very high concern in the European Union. A biobased solvent, 2-methyloxolane (MeOx), was recently authorised for food extraction and could be an alternative to HEX. Two previous studies investigated the use of MeOx-defatted soybean meal (SBM) in the diets of dairy cows and growing beef cattle. However, only SBM was studied, and it contained a high level of MeOx residues (977 mg of MeOx/kg DM).Our objective was to evaluate the effects of HEX- vs. MeOx-defatted SBM and rapeseed meal (RSM) on dairy cows' performance and N utilisation.Thirty-six dairy cows (10 primiparous and 10 multiparous Holstein, 10 primiparous and 6 multiparous Montbéliarde) were enrolled in a continuous factorial experimental design with 2 oilseeds (SBM and RSM) × 2 solvents (HEX and MeOx): SBMHEX, SBMMeOx, RSMHEX, and RSMMeOx. The experiment lasted 9 weeks (4-week pre-experimental phase with a common diet + 5-week experimental phase with the experimental diets). The experimental diets were iso-crude protein (CP, 140 g/kg DM) and consisted mainly of hays, a mixture of maize, wheat, and barley grains, and one of the experimental oilseed meals providing 36% of the CP intake. Individual feed intake, milk yield, milk protein and fat contents, and N utilisation traits (ruminal fluid NH3, milk urea, plasma urea and amino acids [AA], N partitioning) were measured in week 9. A fixed linear model including oilseed, solvent, oilseed × solvent, breed, and parity was built. When a covariate was also measured in week 3, the breed and parity effects were replaced by the covariate effect. Data were analysed using equivalence tests.Oilseed meals defatted with MeOx contained 29 to 53 mg/kg DM of MeOx residues, and oilseed meals defatted with HEX contained 42 to 47 g/kg DM of n-hexane residues. Milk yield, milk protein and fat contents, and N partitioning were likely equivalent between SBMHEX and SBMMeOx, despite DM intake (DMI) being unlikely equivalent toward higher intake for SBMMeOx(+1.6 kg/d). With RSM, the DMI and milk protein and fat contents were likely equivalent between RSMHEX and RSMMeOx, but milk yield and N milk:N intake were unlikely equivalent toward lower values for RSMMeOx (−2.2 kg/d and −1.9 g/100 g). Ruminal fluid NH3 and milk urea were unlikely equivalents toward lower values for MeOx compared with HEX for both SBM (−32.4 and −26 mg/L) and RSM (−21.8 and −30 mg/L). Plasma total essential AA (EAA) and urea were likely equivalent between SBMHEX and SBMMeOx, but plasma lysine was unlikely equivalent toward higher concentrations for SBMMeOx (+5.9 µmol/L). Plasma total EAA, lysine, and urea were unlikely equivalent toward lower concentrations for RSMMeOx compared with RSMHEX (−153 µmol/L, −20 µmol/L, and −0.06 g/L).Results on ruminal NH3 and milk urea, as well as on plasma urea for RSM, suggest an unlikely equivalent ruminal CP degradability of properly desolventised oilseed meals, toward lower degradability for MeOx compared with HEX. Future studies may investigate the intestinal digestibility of rumen undegradable protein from properly desolventised MeOx-defatted oilseed meals.

Voluntary feed intake, body composition and metabolic status differed between growing beef cattle fed hexane vs bio-based solvent-extracted soybean meal in a 7-months feeding trial

E. Jorge-Smeding[1], C. Garcia-Vazquez[1], V. Menoury[1], A. Ferlay[1], L. Salis[1], M. Gauthier[1], P. Faure[2], P. Nozière[1], G. Cantalapiedra-Hijar[1]

[1] VetAgroSup, INRAE, UMRH, Route de Theix, 63122 Saint-Genès-Champanelle, France, [2] INRAE, HERBI-PÔLE, Route de Theix, 63122 Saint-Genès-Champanelle, France

The use of hexane (HEX) for soybean meal (SBM) production is under discussion because of safety concerns. The 2-methyloxolane (MeOx) is an alternative, bio-based solvent, that requires long-term evaluation regarding animal performance and metabolic effects of chronic exposure. This study evaluated the use of HEX- vs MeOx-extracted SBM, supplemented (7 g/d of Smartamine®) or not with rumen protected methionine, on the performance and metabolism of 36 growing-fattening Charolais young bulls [251 ± 22 days of age, 337 ± 39 kg body weight, (BW), n = 9/treatment] across three consecutive feed efficiency test periods (70 days each). All diets had a similar feed composition (main composition: grass silage 55 %, energy concentrates 29.4 %, SBM 9 %, DM basis). Diets contained 1.0 mg HEX/kg DM and 89.8 mg MeOx /kg DM, respectively. The dry matter intake (DMI, daily) and BW (fortnightly) were recorded and the average daily gain (ADG) and feed conversion efficiency (FCE) were calculated for each period. Blood plasma samples were taken at the midpoint of each and stored (−80 °C) until the analysis of non-esterified fatty acids (NEFA), glucose, insulin and leptin through commercial colorimetric or ELISA kits. The surrogate insulin sensitivity indexes RQUICKI and HOMA were calculated. The plasma metabolomic profile was determined only in period 1 (MxP Quant 500 kit, Biocrates Life Sciences, Austria). At slaughter, carcass composition was estimated based on the 6th rib composition. Data were analysed as repeated measures (fixed effects: SBM type, Met supplementation, the period and all their interactions; random effect: the animal; covariance structure: AR(1)) in SAS 9.4 (SAS Institute Inc., Cary, NC, USA). Metabolomic data, and carcass traits at slaughter were analysed considering the SBM, Met and their interaction as fixed effects. Tukey test was used for post-hoc comparisons. Differences were declared at $P \leq 0.05$ and tendencies at $P \leq 0.10$. False discovery rate (FDR)-adjusted P-values were also applied for metabolomics data. The DMI was higher in MeOx vs HEX only in period 3 (SM×Period $P<0.01$). The FCE, ADG and carcass weight increased with Met supplementation only in the MeOx diets ($P \leq 0.05$). Fat content of the 6th rib was higher in HEX vs MeOx regardless of Met ($P=0.05$); no evidence of difference was found for muscle and bone tissues contents. Estimated carcass fat (+3.6 %), muscle (−0.9%), and muscle-to-fat ratio (−4.3 %) tended to differ in HEX vs MeOx diets regardless of the Met ($P \leq 0.08$). Plasma NEFA increased ($P<0.01$) from period 1 to 2 only in MeOx (SM×Period $P=0.04$). Regardless of the Met level, plasma glucose tended to be higher ($P=0.07$) in HEX vs MeOx only in period 3 (SM×Period $P=0.09$). Plasma insulin was overall higher in HEX vs MeOx ($P=0.01$) regardless of Met; leptin was higher in HEX vs MeOx only when Met was supplemented (SM×Met $P=0.10$). The HOMA index was overall higher in HEX vs MeOx, and RQUICKI was higher in HEX vs MeOx only in period 1 (SM×Period $P=0.07$). Several long-chain poly-unsaturated phosphatidylcholines were lower in HEX vs MeOx ($P<0.05$, FDR>0.10). Our results suggest that chronic exposure to hexane may cause subclinical yet evident alterations in energy and lipid metabolism of growing beef cattle, potentially impacting the long-term control of voluntary feed intake. This study may provide the first experimental indication of adverse metabolic effects of chronic dietary exposure to low levels of hexane residues in mammals.

Determining the impact of anaerobic digestion on the host-range and potential mobility of antimicrobial resistance genes in dairy manure

N. Rahman[1], A. Z. Rahman[1], N. Cicek[2], T. A. Mcallister[1,3], H. Derakhshani[1]
[1] University of Manitoba, Department of Animal Science, 12 Dafoe Rd, R3T 2N2 Winnipeg, Canada, [2] University of Manitoba, Department of Biosystems Engineering, 12 Dafoe Rd, R3T 2N2 Winnipeg, Canada, [3] Agriculture and Agri-Food Canada, Lethbridge Research Centre, 5403 1 Ave S, Lethbridge, T1J 4B1 Lethbridge, Canada

Antimicrobial resistance (AMR) is a critical One Health threat, with livestock manure serving as a major environmental reservoir of antimicrobial resistance genes (ARGs) and mobile genetic elements (MGEs). Reducing resistance dissemination at the manure management stage represents a strategic intervention point. Anaerobic digestion (AD), widely used for organic waste stabilization and biogas production, has been proposed as an effective strategy to reduce pathogen and ARG loads in manure. However, its impact on the dynamics of ARG carrying microbiome (resistome) and associated MGEs (mobilome) remains poorly understood. In this study, we investigated temporal shifts in microbial community composition, ARG abundance, and ARG–MGE associations during laboratory-scale AD of dairy manure. Manure from a commercial dairy farm was fed into a continuously stirred AD at 3 one-month intervals. Samples were collected from manure, 0 and 1 h post feeding the AD, and 1, 2, 3, and 4 wks post-feeding. Samples were processed through two pipelines: direct shotgun metagenomics using Illumina short-read sequencing, and culture-enriched metagenomics (CEMG) under aerobic and anaerobic conditions using a hybrid metagenomic approach (Illumina and Nanopore sequencing). For CEMG, samples were plated on brain heart infusion agar supplemented individually with ceftiofur, lincomycin, tetracycline, vancomycin, erythromycin, or ampicillin, each applied at their respective recommended breakpoint concentrations, to enrich low-abundance taxa associated resistomes. Enriched cultures were pooled and sequenced using Illumina and Oxford Nanopore platforms, to enable hybrid metagenomic assembly and generation of a high-quality contig database. A total of 196 contigs exhibited ARG–MGE co-localization. Direct metagenomic reads from all time points were mapped to this database to monitor temporal shifts in ARG-carrying taxa and mobility linkages. AD induced rapid and substantial ecological restructuring; Streptococcus parauberis and Vagococcus fluvialis, abundant in raw manure, were eliminated from digestate samples from 1 h through wk 4. At the order level, fresh digestate exhibited a 83–95% reduction in dominant manure-associated taxa, including Bacillales, Peptostreptococcales, Eggerthellales, and Pseudomonadales. Although Bacteroidales displayed transient enrichment at wk 2 (+30.6%), its abundance remained 30.7% lower than manure by wk 4. Lactobacillales fluctuated during AD, but declined by 82% at the final time point. Total ARG content declined sharply following AD, with fresh digestate showing an 83% reduction relative to manure and a maximum reduction of 89% at wk 2. Despite a modest increase at wks 3 and 4, ARG levels remained 4-9-fold lower than untreated manure. ARGs conferring resistance to clinically relevant drug classes, including aminoglycosides, lincosamides, and tetracyclines, exhibited sustained suppression during AD, remaining approximately 80-97% lower than raw manure by wk 4. Notably, these ARGs were linked to diverse MGEs, including plasmids, integrative genetic elements (IGEs), and phages, highlighting a concurrent reduction in mobilizable resistance potential. Overall MGE abundance declined by 40-45% across the digestion timeline. Collectively, AD induced marked ecological restructuring and substantial resistome attenuation in livestock manure, reducing ARG burden while diminishing mobility potential.

Utilizing the shape of the heart to decrease mortality in pig breeding.

Ø. Nordbø[1], T. Ermens[1], E. Grindflek[1]
[1] Topigs Norsvin, Storhamargata 44, 2317 Hamar, Norway

Heart failure is a known cause of sudden death in pigs, but the underlying morphological and clinical factors, such as cardiac remodeling and reduced stroke volume are difficult to assess non-invasively in live animals. The external surface of the heart can be extracted from full-body CT images, and previous studies have shown an association between large heart volumes and increased mortality. However, direct selection for smaller heart size may not be a sustainable long-term strategy. In this study, we examine whether the shape of the pig heart surface contains additional biologically relevant information that could support breeding programs beyond what volume alone provides. Using image registration techniques on 1,849 segmented hearts from a synthetic line, we extracted 481 surface coordinates to create a structured multivariate dataset. Principal component analysis (PCA) showed that the first three components explained 70% of the variation in heart shape. We then applied partial least squares (PLS) regression to identify shape features correlated with relevant response variables, such as estimated breeding values (EBVs) for mortality from rearing to finishing. Surface coordinates and corresponding EBVs were split into an 80% training set and 20% test set. The highest predictive performance was obtained with two PLS components, yielding an R^2 of 0.032 for the test set. Using the full dataset with two components produced a similar R^2 of 0.033, corresponding to a correlation of 0.18. Both PLS score vectors were correlated with heart volume (r = 0.80 and 0.32). These findings indicate that limited additional information related to mortality exists in heart surface shape beyond total heart volume. Heart volume itself showed a correlation of 0.13 with mortality EBV, confirming its importance. To exploit CT-derived cardiac phenotypes for improving survival in pig breeding, we propose incorporating heart volume as a correlated trait within multivariate EBV prediction models.

Milking-time indicators link vacuum dynamics, milk flow, and milk quality in Holstein herds

M. Santinello[1], L. Pascarella[2,3], R. Matera[1], P. Federica[1], S. Biffani[4], G. Neglia[1], R. Negrini[3]
[1] University of Naples Federico II, Veterinary Medicine and Animal Production, Via F. Delpino 1, 80137 Napoli, Italy, [2] Italian Breeder Association, Via XXIV Maggio 44/45, 00187 Roma, Italy, [3] University Cattolica del Sacro Cuore, Animal Science, Nutrition and Food, Largo A. Gemelli 1, 20123 Piacenza, Italy, [4] Consiglio Nazionale delle Ricerche (CNR), Institute of Agricultural Biology and Biotechnology (IBBA), Via A. Corti 12, 20133 Milano, Italy

Variations in milking vacuum affect mechanical stress on teat tissue, with potential consequences for udder health and milk quality. This study evaluated key milking-time test indicators in commercial Holstein herds, and their contemporaneous associations with milk yield, composition, and somatic cell score (SCS). Data comprised 4,707 test-day records from 4,149 cows in 215 Italian herds equipped with conventional milking parlors. Vacuum was continuously recorded at the short milk tube (SMT) and mouthpiece chamber (MPC) to characterize machine-on time, milk let-down (MLD), overmilking, positive and negative cyclic vacuum fluctuations (CVFmax and CVFmin, respectively). A random forest model identified the milking-time test, herd and animal indicators most strongly associated with variation in SCS. Therefore, the most relevant milking-time test indicators were included in repeated linear mixed models to quantify their effects on milk yield and composition. Moreover, similar mixed model approaches were used to determine how the most important herd and animal characteristics influenced milking-time test indicators. Overmilking duration, SMT vacuum and positive and negative CVFs during the main milking phase were the variables most strongly associated with SCS variation. SCS significantly increased when overmilking exceeded 30 s and peaked beyond 60 s (2.58 vs. 2.93, respectively), while lactose was significantly lower in the ≥60 s class (4.78%), milk yield per session was unaffected. SMT vacuum influenced milk yield and composition: SCS were significantly highest at 37.3-38.0 kPa (3.08) and lowest at 39.3-39.8 kPa (2.45), while lactose was lowest between 36.7-37.3 kPa (4.76%) and greatest between 38.7 and 39.8 kPa. Greater CVFmin and CVFmax were significantly associated with reduced fat content once fluctuations exceeded ~ 3.50 kPa. Large-size herds (>329 lactating cows) had significantly shorter machine-on time (323 vs. 337 s) and overmilking (47.7 vs. 59.3 s), higher milk flow (3.11 vs. 2.70 kg/min), consistent with the higher-genetics cow populations which can likely be found in larger operations. However, large size herds showed significantly longer milk let-down duration (34.8 vs. 24.7 s), likely reflecting reduced pre-stimulation in high-throughput routines. Similar trends were observed in high-yielding herds (>38 kg/day) that had significant shorter machine-on time (326 vs. 340 s), lower relative overmilking (15.1% vs. 18.4%), longer milk let-down (9.67% vs. 8.50%), and higher milk flow (3.17 vs. 2.73 kg/min) compared with low-yielding herds (<34 kg/day). Finally, MPC vacuum significantly declined as parity order increased, from 21.8 kPa in primiparous cows to 12.8 kPa in cows ≥4 parities, consistent with progressive teat canal widening. Overall, milking-time test indicators captured biologically relevant variation in milk yield and composition. Their integration into routine milking assessments may support early detection of deviations and targeted adjustments of milking protocols to improve udder health and efficiency.

A machine learning framework for early and dynamic prediction of milk, fat, and protein yield of dairy cows

M. Hagens[1], I. Adriaens[1], W. Garcia Herrera[1], A. Marubayashi Hidalgo[1], M. Sol[1]
[1] CRV, GInS, Rijksweg west 2, 6842 BD Arnhem, Netherlands

Accurate prediction of lactation curves for milk, fat, and protein yield of individual cows is essential for decision-making in farms and dairy processing. They serve as basis for herd planning and insemination decisions, cow-comparison key figures such as net returns and lactation index, and forecasting in dairy plant production planning. By comparing the expected production with the actual yields, the model enables early detection of deviations that may signal health or welfare concerns, supporting proactive interventions. This study presents a machine learning–based lactation model capable of predicting daily milk, fat, and protein yields for individual cows up to 500 days in milk, both prior to calving and dynamically throughout lactation after new test-day records become available. The model incorporates genetic information, herd levels, animal levels, pregnancy status, and auxiliary characteristics such as parity, calving season, and age. The herd and animal level effects express herd and animal performance relative to population standard curves. It is trained and tested using a large dataset of test-day records from 1.9 million lactations from 8,981 Dutch herds, representing a highly diverse operational environment. This scale allows the model to generalize across herd types and management conditions, which is crucial for a robust model. Before calving, the model predicts the first 305 days of lactation with median absolute errors (MEDAE) of 3.64 kg for milk, 0.16 kg for fat, and 0.13 kg for protein yield, corresponding to percentage errors of 15.3%, 15.3%, and 14.6%, respectively. Prediction accuracy for later lactation days is slightly lower, largely due to the lack of reliable pregnancy information prior to calving. Once the lactation begins and new test-day records are incorporated, accuracy improves, with the MEDAE decreasing to 2.45 kg milk, 0.13 kg fat, and 0.10 kg protein, and percentage errors of 11.3%, 12.5%, and 11.7%, respectively. The predictions provide a valuable benchmark for evaluating expected versus actual performance of the cow. As lactation progresses, incorporating new test-day data further refines accuracy, enabling reliable estimation of expected performance, dry-off yield, and cumulative (expected) 305-day and lactation production of an animal, herd, or herd groups, such as by parity. This information can be used as early-warning indicators of health and welfare concerns, as well as determining the optimal insemination moment which can extend the lactation. Extending lactations reduces the number of transition periods for the cow, which reduces the health risks and increases welfare. Because the model can forecast both ongoing and future lactations, it supports medium- to long-term planning and can be used to predict expected production for entire herds or herd groups up to two years ahead, contributing to healthier cows and improved decision-making.

Use of Thermography for Monitoring Udder Health Status in Dairy Cows

P. Baronchelli[1], G. Gislon[1], M. Zucali[1], L. Bava[1], N. Palladini[1], S. Bonizzi[1], M. Pavolini[1], S. Sari[1], A. Tamburini[1], M. Battelli[1], A. Sandrucci[1]

[1] University of Milan, Department of Agricultural and Environmental Sciences - Production, Land, Agroenergy, Via Celoria 2, 20133 Milano, Italy

Hypothesis. Precision livestock farming is currently seeking new alternative methods for monitoring animal health and welfare. Among these, infrared thermography is emerging as a technology that allows the acquisition and processing of thermal information, enabling the early detection of alterations in blood flow and skin temperature associated with various pathological processes. Thermography is a practical, reliable, and non-invasive method for monitoring animal health status. Today, it is mainly used in experimental studies on dairy cows to monitor hoof and udder health. It was hypothesized that udder surface temperature measured by infrared thermography is associated with mastitis infections, including subclinical cases, and with changes in milk production, milk flow parameters, and differential somatic cell count. Experimental methods. Data were collected weekly using a FLIR E96 thermal camera to capture thermal images of the udder approximately two hours before milking; milking was monitored using continuous electronic milk flow meters (LactoCorder, WMB, Balgach, Switzerland). Milk samples were collected to evaluate the differential somatic cell count and the concentration (cells/mL) of neutrophils, macrophages, and lymphocytes using the Vetscan DCQ Milk Analyzer. Statistical analyses. Data processing and analysis were carried out using Microsoft Excel and JMP software. Generalized Linear Mixed Model (GLMM) analyses were conducted to investigate the relationships among the different measured parameters. Results and discussion. The average milk yield during the study period was 14.0±4.09 kg per milking, with a maximum milk flow rate of 3.56±1.27 kg/min. Another interesting parameter evaluated was the percentage duration of the plateau phase, which averaged 34.8±20.87% of the total milking time. Regarding udder health variables, maximum electrical conductivity (6.00±0.47 mS/cm) and total leukocyte somatic cell count (TLC; 4.72±0.59 $\log_{10}$ cells/mL) were considered. In terms of average percentage composition, neutrophils represented the largest proportion (53.8± 13.3%), followed by macrophages (30.7±15.2%) and lymphocytes (15.6±8.10%). Concerning the temperature measured on the udder surface, both the mean and maximum values were evaluated for each cow; on average, these values were 35.1±0.90°C and 38.4±0.88°C, respectively. For TLC values above 5 $\log_{10}$ cells/mL, reductions of up to 5.4 kg of milk per milking and up to 14.4% in the percentage plateau phase were recorded; moreover, maximum electrical conductivity increased by 0.38 mS/cm were observed. These parameters may be considered early indicators of the presence of a mammary infection. The temperature measured on the udder surface did not show a significant relationship with parameters directly associated with udder health: despite increases in total leukocyte somatic cell count and electrical conductivity, maximum temperature remained stable at around 38.2°C. Instead, it appeared to be more closely associated with milk yield: when production exceeded 16 kg per milking, an increase in udder surface temperature of up to 0.6°C was observed. Conclusion. The importance of production parameters for monitoring, through the integrated use of various tools, udder health status and identifying possible diseases is emphasized; at the same time, thermography can be used to identify healthy cows with a more active and well-functioning metabolism.

Methods to describe the behavioural resilience of cows after a systemic inflammatory challenge

S. Prins[1], M. Taghipoor[2], I. Veissier[1], F. Blanc[1], A. De Boyer Des Roches[1], L. Aube[3], D. Ledoux[1]
[1] Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, , 63122 Saint-Genès-Champanelle, France, [2] Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, , 91120 Palaiseau, France, [3] INRAE, Institut Agro, UMR Pegase, , 35590 Saint-Gilles, France

Resilience is the capability of an animal to be minimally affected by a disturbance or to return rapidly to the state before the disturbance. A change in behaviour is an early indicator of disease and could indicate the capacity of the animal to cope with the disease. We aimed at designing a mathematical method to assess the behavioural resilience of cows to further study the links between behavioural and clinical resilience. Fourteen Holstein cows were challenged with intravenous lipopolysaccharide (LPS) injection. The behaviour of the cows was continuously monitored using collar-attached accelerometers from 30 days before to 60 days after LPS injection (T0). Theoretical points in time after T0 were defined: the beginning of the deviation of resting from baseline (Tb) and the end of LPS impact on resting behaviour (Te). Two mathematical methods were tested: a regression line method on the cumulative data (RC) and a regression line method on the first derivation of the cumulative data (RD). The baseline for resting behaviour was defined using a regression based or on the cumulative resting time per hour (RC) or on the first derivation of the cumulative resting time (RD) over the last six days before T0. In both methods, Tb was the first point exceeding the baseline ± 2 SD. Te was detected by RC when the regression line stayed within 5% of the baseline slope before T0, and when 95% of the residuals were within ±2 SD of the baseline, with both conditions satisfied for at least six consecutive days. Te was detected by RD when the values returned to the baseline ± 2 SD for at least six consecutive days. Four experts (biologists) identified Tb and Te by visual observations of the first derivation of the cumulative data. The points (Tb, Te) from RC and RD were compared with those of experts using Bland-Altman analysis (bias and 95% limits of agreement (LoA)) and calculating the Lin's concordance correlation coefficient (CCC). Both mathematical methods and experts found Tb in all 14 cows. Te was found in 10/14 cows using RC, 11/14 cows using RD and in 12/14 cows by the experts. Tb was found at 4.5 h (± 8.0) by RC, -7.2 h (± 6.7) by RD and -14.2 h (± 13.1) by experts. Te was found at 190.8 h (± 42.7) by RC, 155.9 h (± 58.1) by RD and 194.8 h (± 21.5) by experts. Between RC and experts, a bias of 19 h [lower LoA –upper LoA] [(-17) – 45 h] for Tb and a bias of -12 [(-112) – 88] for Te, and between RD and expert a bias of 7 [(-29) – 43] for Tb and a bias of -39 [(-170) – 92)] for Te. Between RC and experts, the CCC was 0.4 for Tb and 0.2 for Te. The CCC was 0.3 and 0.4 between RD and experts for Tb and Te, respectively. Both mathematical methods were able to identify both points of interest with a smaller marge of error for Tb than Te. For now, the RC method appears to produce results closer to those of the experts than the RD method when determining Tb. No clear distinction was observed between the two mathematical methods when the bias, LoA and CCC of both methods were considered for Te. Further work is ongoing to refine both mathematical methods and then apply them on clinical parameters in order to study the links between behavioural and clinical resilience.

Inferring transmission routes of Staphylococcus aureus using high-resolution contact data in dairy cattle

H. Marina[1], J. Sanchez[2], S. Woudstra[3], I. Hansson[4], L. Rönnegård[1]
[1] Swedish University of Agricultural Sciences, Ulls väg 26, 75651 Uppsala, Sweden, [2] University of Prince Edward Island, 550 University Ave, C1A 4P3 Charlottetown, Canada, [3] University of Copenhagen, Grønnegårdsvej 8, 1870 Frederiksberg Copenhagen, Denmark, [4] Växa, Ulls väg 26, 75651 Uppsala, Sweden

Understanding how mastitis-causing bacteria spread within dairy herds is essential for designing targeted control strategies aiming to improve udder health in dairy cattle. We hypothesised that integrating contact networks with high-resolution sensor data and strain-level pathogen information enables the identification of transmission routes and the individual contribution of each cow to pathogen transmission. The objective of this study was to apply a previously developed likelihood-based computational framework to contact network data from a commercial dairy operation to elucidate transmission dynamics of Staphylococcus aureus (S. aureus) in the herd. Data were obtained from 250 lactating cows monitored over five months in a commercial dairy barn equipped with a real-time location system (RTLS) that recorded positions at 1-s intervals. The RTLS provided information on proximity contacts, area utilisation similarity, and sequential cubicle occupancy, which were integrated with milking parlour records specifying the time and stall position of each cow at each milking event. Concurrently, quarter-level milk samples were collected at bi-weekly intervals, and cultured S. aureus strains were typed using a randomly amplified polymorphic DNA (RAPD)-PCR test. The sensor information was used to create dynamic transmission networks that could explain the transmission of S. aureus from infected to susceptible cows between the sampling time points. These networks were constructed from proximity data, area utilisation similarity, and sequential use of milking units and resting cubicles. Transmission dynamics were modelled using an individual-based stochastic SIS (Susceptible–Infected–Susceptible) framework on candidate contact networks, where each cow's infection risk was determined by network-derived effective contact exposure to infected cows and by S. aureus–specific transmission and recovery parameters (β, γ) estimated from longitudinal bacteriological milk-sampling data. The likelihood of the observed infection sequence was computed, and networks were compared using maximum likelihood estimation to identify the most plausible transmission pathway. Individual-level metrics were derived to quantify transmission potential (risk-transmission index, defined as the proportion of effective contacts relative to total contacts), susceptibility, and resilience, accounting for the frequency, duration, strength, and spatial context of effective contacts with infected individuals. The inferred transmission patterns revealed substantial differences in likelihood across transmission networks and in their relative contributions to the endogenous persistence of S. aureus within the herd. The role of infected cows was evaluated individually across proximity-based, milking-order, and cubicle-use transmission pathways, revealing marked heterogeneity in their contribution to effective transmission events. These findings demonstrate that combining sensor-derived contact information with a stochastic network-based modelling framework enables reconstruction of biologically plausible transmission routes. The proposed framework provides a quantitative basis for identifying high-risk individuals and transmission pathways within barns, thereby supporting the development of targeted mastitis control strategies based on precision livestock data.

Responses of dairy cow to common stressors: effects on milk production and feeding behaviour traits

M. Braidot[1], A. Cabbia[1], E. Florit[1], M. Corazzin[1], A. Romanzin[1]
[1] University of Udine, Department of Agricultural, Food, Environmental and Animal Sciences,, Via sondrio 2/A, 33100 Udine, Italy

The efficiency of the dairy livestock sector is a fundamental point given the near future worldly challenges, and precision farming surely is a useful tool to guarantee an adequate efficiency level. In this field, the high-frequency automatic data collection and interpretation represent the key point to address an optimal production level. Several aspects could be considered, but the feeding behaviour is one of the most monitored traits because it is closely linked to two main aspects as feed efficiency and animal welfare. Nowadays, this aspect is easy to monitor given the widespread adoption of technology at several production stages, integrated in various devices present in commercial farms. The presence of a stress condition in dairy cows generally leads to a modification in normal feeding behaviour, reducing the eating time (ET) and the rumination time (RT). The most common primary sources of stress in dairy cows are mastitis (M) and lameness (L), but heat stress (HS) surely also plays an important role among stressors. Solutions to assess drops in milk yield under stress conditions (MY) have been extensively studied, but models to quantify changes in animal behaviour, mainly ET and RT, are still lacking. The current study tries to contribute in this sense, adopting a smoothing approach to identify and characterise perturbations in three different aspects ET, RT and MY. Raw data were collected from 350 Italian Simmental cows in some dairy farms in north-east Italy provided with an automatic milking system and accelerometers, and within this population, cows with a lactation period of at least 150 days were selected. To evaluate the response time, the recovery time, and to quantify the production and feeding behaviour losses, a double-curve approach was used. Differences between the two curves characterised by different smoothing parameters ($\lambda = 100$ and $\lambda = 10{,}000$) were fitted with a linear mixed-effect model. The lactation stage (early, mid, late), parity (primiparous, multiparous) and perturbation cause (M, L, HS) were considered as fixed factors while the effect of farm and cow (nested within farm) were included as random. The p-values for multiple comparisons were adjusted using the false discovery rate method. Results obtained indicate that L generates the longest (30.6 and 28.8 d, respectively) and most difficult perturbations to recover, both for MY and ET. Moreover, it also caused the greatest loss in milk production (14.7 kg). The HS caused the greatest losses regarding feeding behaviour (175.2 and 210.3 min, ET and RT, respectively). Overall, seems that M had a lower impact on aspects considered. Primiparous cows showed faster responses to stress but slower recovery times compared to multiparous ones. However, multiparous exhibited a greater total MY losses. The method applied has been shown to be effective to quantify losses and recovery time at individual level proving to be an effective solution to evaluate response of each animal to physiological and environmental events adding useful information to enhance the livestock sustainability.

Innovative functional modelling framework reveals black globe temperature as the most robust predictor of circadian heat related behavior in grazing dairy cows

S. Czaplicki[1,2], H. Soyeurt[2], I. Dufrasne[1]
[1] University of Liège, Fundamental and Applied Research for Animals and Health, Avenue de Cureghem 6, 4000 Liège, Belgium, [2] University of Liège, Modelling and development, Passage des déportés 2, 5030 Gembloux, Belgium

Capturing 24-h behavioral responses to heat stress remains analytically challenging due to strong non-linearities, individual variability, and the temporal structure of grazing systems. Traditional analyses typically ignore circadian dynamics or assume linear thermal responses, limiting their capacity to detect biologically relevant shifts. We aimed to develop an advanced modelling framework capable of (i) identifying which climatic index best predicts circadian behavioral rhythms under pasture conditions, and (ii) quantifying how rhythms re-time under hot vs. cool days. We hypothesized that black globe temperature (TBG), integrating radiation and air temperature, would outperform other indices. We analyzed 2.46 million accelerometer-based behavioral records collected at 5-min intervals from 86 grazing Holstein cows over two summers. Eight climatic indices were derived from hourly meteorological data. Circadian dynamics of twelve behavioral traits were modelled using big additive models (BAM) with cyclic cubic splines, allowing smooth 24-h periodicity and scalable computation on large datasets. Each climatic index was tested via a dedicated spline term, and performance was compared using AIC. Days were classified into cool (≤23.6 °C TBG) and hot (≥29.4 °C) based on empirical quantiles, and BAMs were refitted for each class to quantify functional differences in rhythm amplitude, phase, and shape. Confidence bands were used for inference on whole-curve differences rather than pointwise values, enabling functional comparison of circadian patterns. TBG provided the lowest AIC in 10/12 behaviors, clearly outperforming THI, CCI, HLI, WBGT and other indices. Functional predictions revealed significant, systematic re-timing of behaviors between hot and cool conditions, as evidenced by non-overlapping 95% simultaneous confidence intervals across extended time windows. Under heat, cows shifted rumination and resting towards the night–early morning, increased standing in early morning and late afternoon, and reduced midday activity—patterns consistent with circadian thermoregulatory adjustments. These results demonstrate that the BAM-based functional approach uncovers subtle rhythmic reorganizations that would remain undetected with classical linear or mean-based analyses. This study introduces a novel, scalable functional modelling pipeline combining BAM, cyclic splines and quantile-based thermal classification to dissect circadian behavioral responses at high temporal resolution. Black globe temperature emerged as the most reliable environmental driver of circadian dynamics in grazing cows, highlighting the central role of solar radiation in shaping heat-related behavior. This framework offers a methodological advance for heat-stress research and provides a transferable tool for evaluating thermal stress in precision livestock systems, especially where large behavioral time-series and complex non-linear rhythms must be analyzed.

Impact of Weaning and THI on Dairy Calf Behavior

M. Saladini Vieira Salles[1], M. Benetti Figueiredo[1], L. Schneider Gheller[1], M. Martison Martins[2]
[1] Animal Science, Av. Bandeirantes, 2419, 14030-670 Ribeirao Preto, Brazil, [2] University of Sao Paulo, School of Animal Science and Food Engineering, Rua Duque de Caxias Norte, 13635-900 Pirassununga, Brazil

Weaning is a critical phase in the management of dairy calves, characterized by significant changes in behavior and feed intake, which can be strongly influenced by ambient temperature. However, the extent of this impact remains unclear. The use of electronic monitoring devices can provide detailed assessments of animal behavior, feed intake, and the temperature-humidity index (THI). This study aimed to evaluate behavioral (activity and inactivity) and feeding (concentrate and water intake) changes in dairy calves during weaning and to investigate the influence of the temperature-humidity index (THI) on these variables. Thirty-seven male Holstein calves were monitored during weeks 7 (pre-weaning), 8 (start of weaning), and 9 (weaning progress). Calves were fed milk replacer via an automated liquid diet feeder, and their housing was equipped with automated concentrate feeders and water drinkers to allow individual monitoring. Milk replacer was offered at 6 L/day (840 g total solids) until 49 days of age (week 7), then reduced to 4 L/day (560 g total solids; week 8) and 2 L/day (280 g total solids; week 9). Activity and idleness were continuously recorded using commercially available collars fitted to calves throughout the weaning period. Behavioural data were collected hourly and then grouped into time periods (morning, afternoon, and evening), while intake data were recorded daily. THI was recorded throughout the experimental period (average 73.3, maximum 80.0 and minimum 61.0). Multivariable mixed models were used to analyze associations between week of life (7, 8, and 9) and behavioral and feeding variables, with week 7 as the reference because it preceded the onset of weaning. Activity increased by 12.55 min/day in week 8 ($P = 0.0083$) and 42.34 min/day in week 9 ($P < 0.0001$) compared to week 7. Idleness decreased similarly, by 12.54 min/day in week 8 ($P = 0.0083$) and 42.33 min/day in week 9 ($P < 0.0001$). Activity was higher and idleness lower in the morning and evening than in the afternoon, with differences of 11.99 and 17.70 min/day, respectively. In addition, for each one-unit increase in THI, activity increased by 4.34 min/day, with a corresponding decrease in idleness ($P < 0.0001$). Concentrate intake increased by 0.41 kg/day in week 8 and 1.09 kg/day in week 9 ($P < 0.0001$) compared to week 7. Each one-unit increase in THI was associated with a 5.6 g/day decrease in concentrate intake ($P = 0.0302$). Water intake increased by 1.24 L/day in week 8 and 3.27 L/day in week 9 ($P < 0.0001$), along with an additional 74.5 mL/day increase for each unit rise in THI ($P < 0.0001$). The observed increase in activity and reduction in inactivity following the onset of weaning suggest heightened restlessness in calves, likely associated with foraging behavior and dietary adaptation due to reduced milk supply. Weaning induced significant behavioral and feeding changes, which were further modulated by THI, highlighting the importance of environmental management for calf welfare. Quantification of resilience indicators in broiler chickens through the analysis of growth and feed intake dynamics

Y. Guyot[1], I. Kyriazakis[2], M. Taghipoor[3], V. Jonchère[4], E. Pampouille[1], C. Souchet[1], A. Narcy[4], B. Méda[4]
[1] ITAVI, Institut Technique de l'Aviculture, 37380 Nouzilly, France, [2] School of Biological Sciences, Queen's University, BT9 5DL Belfast, United Kingdom, [3] Université Paris-Saclay, INRAE, AgroParisTech, UMR MoSAR, 91120 Palaiseau, France, [4] INRAE, Université de Tours, BOA, 37380 Nouzilly, France

Improving the resilience of broiler chickens is increasingly important to ensure sustainable poultry production under external challenges such as climatic variability or pathogen exposure. Resilience is a multifaceted biological trait defined as the ability of an animal to withstand, adapt to, and recover from environmental or physiological perturbations while maintaining productive performance. Because resilience cannot be measured directly using conventional end-point traits, innovative quantitative approaches based on longitudinal data are required. The objective of this study was to develop and validate a methodology to quantify key traits of resilience in fast-growing broiler chickens by analysing the dynamics of body weight (BW) and cumulative feed intake (CFI) in response to a perturbation. The approach relies on modelling performance trajectories and characterising stressor-induced deviations. First, non-perturbed ("reference") trajectories for BW and CFI are estimated by fitting appropriate nonlinear models to longitudinal time-series data. An iterative procedure based on residual autocorrelation analysis progressively excludes perturbed observations until no significant autocorrelation remains. Deviations between observed data and the corresponding reference trajectory are then quantified, and their temporal dynamics are described using an asymmetric Gaussian function. The response to a perturbation is characterised using six complementary parameters: (i) maximum deviation amplitude, (ii) time of maximum deviation, (iii) onset time, (iv) recovery time, (v) skewness of the deviation curve, and (vi) the integral under the curve representing cumulative impact. Together, these parameters provide an integrated description of both resistance to perturbation and recovery capacity, two major components of resilience. The methodology was evaluated using data from a controlled coccidia infection challenge (Eimeria maxima) in broiler chickens fed diets diluted with increasing levels of lignocellulose. Although CFI did not differ significantly between diets overall, resilience analysis revealed marked differences in response dynamics. Compared with the control diet, birds fed the most diluted diet (HF; 15% lignocellulose) showed a significantly lower maximum deviation for both CFI and BW (−4% vs. −11%, $P < 0.001$), as well as a lower cumulative impact, assessed by the integral of the deviation curve (CFI: −17 vs. −50 %·d; BW: −21 vs. −63 %·d). In addition, HF birds exhibited a shorter perturbation duration for BW (8.7 vs. 11.1 d; $P < 0.05$) and a delayed onset of the BW response (4.7 vs. 3.8 d; $P < 0.01$), further supporting a more resilient response. Overall, analysing BW and CFI dynamics provides a robust framework for quantifying resilience in broiler chickens. The proposed methodology can be applied at both individual and flock levels and offers promising applications for genetic selection of more resilient animals, as well as for evaluating nutritional or management strategies aimed at improving robustness and adaptability in poultry production systems. In this perspective, the method will soon be applied to individual longitudinal data from fast-growing chickens exposed to a thermal challenge (heat stress).

Using ultra-wideband tracking technology to monitor activity and area use in broiler breeders

M. Van Der Sluis[1], R. Van Emous[2]
[1] Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, Netherlands, [2] Wageningen University & Research, Animal Nutrition, P.O. Box 338, 6700 AH Wageningen, Netherlands

In Europe, broiler breeders are commonly housed in large flocks in floor/slat systems. Within these flocks, the interaction between male and female birds is of great importance for the production of fertilized eggs. However, manually monitoring the behaviour of individual broiler breeders is very challenging, due to their large numbers and similar appearance. Here, an ultra-wideband (UWB) tracking system was implemented to record the location and movement of individual broiler breeders kept in a commercial house (59 x 14 m) in a flock of 5,950 birds (350 males and 5,600 females). The house was physically separated in two identical – but mirrored – halves. At 23 weeks of age, 56 broiler breeders (n = 28 male, n = 28 female; in a 50/50 split across the two sides of the house) were fitted with an UWB tag in a backpack. The body weight of all birds was recorded, and the comb (on a scale from 1 to 3) and overall condition (scale 1-5) of males were scored. For females, the feathering (scale 0-5), pinbones (scale 0-3) and wing feathers (scale 0-10) were scored. The UWB tags that were fitted to the birds sent out a signal to receivers in the environment, with a preset sampling rate of approximately one sample every second, although the realized average sampling frequency was lower. The location of the birds was recorded continuously throughout the house, and we here studied the first subset of data from one month of tracking (23-27 weeks of age). During this time span five birds lost their tags, resulting in a remaining sample size of 51 birds (n = 24 females, n = 27 males). Three indicators of activity and area use were determined: 1) distances moved (i.e., the Euclidian distance between subsequent detections of the same bird), 2) functional area use within the house (i.e., the proportion of detections of a bird on the litter, on the slats and in the nest box area), and 3) overall area use (i.e., the proportion of the total house area visited in a day, for which both halves of the house were virtually split into 20 zones). In the analyses, a potential effect of side of the house was accounted for and preliminary results are presented here. An overall average daily distance moved of 2,141 (SD 654) m was observed. Daily distances moved were higher for males than for females (model estimate of 2,435 versus 1,795 m, $p < 0.001$). Within males, no effects of body weight, comb or overall condition on distances moved were observed, and within females, no effects of body weight, pinbones or feathering (no variation present; all females had the same feathering score) were observed (all $p > 0.05$). A link with wing feather score was observed for distances moved ($p < 0.001$), but given the small sample size per feather score, this requires further investigation. In terms of functional area use, males spent more time in the litter area than females did ($p < 0.001$), while females spent more time on the slats and in the nest box area than males ($p < 0.001$and $p = 0.009$, respectively). The overall average number of zones visited was observed to be 14.9 (SD 3.8) out of 20 (approx. 75% of the available area). No difference was observed between the sexes ($p > 0.05$), but the number of zones visited decreased during the month of recording (estimate = -0.04, $p < 0.001$). Overall, these preliminary results indicate that males and females use the house differently, which can have consequences for the interaction – and reproduction – of males and females. Next steps include further investigation of individual differences and interactions between males and females.

Correspondence-Based Explainable Deep Learning for Automated Recognition of Pre-Competition Stress in Horses

M. Feighelstein#[1], L. Teschke#[2], Y. Solomon[3], T. Ben Harush[3], C. Ricci-Bonot[4], M. Baumgartner[5], A. Zamansky[6]
[1] Tel Hai University of Kiryat Shmona in the Galilee, Engineering Cluster, Tel-Hai Eastern Campus, 1220800 Kiryat Shmona, Israel, [2] University of Applied Sciences (HfWU), Neckarsteige 6-10, 72622 Nürtingen, Germany, [3] Technion - Israel Institute of Technology, Electrical Engineering, Technion City, 3200003 Haifa, Israel, [4] University of Lincoln, Brayford Pool, LN6 7TS Lincoln, United Kingdom, [5] Agroscope, Research Group Equids, Swiss National Stud Farm SNSF Les Longs-Prés, 1580 Avenches, Switzerland, [6] University of Haifa, Computer and Information Systems, 199 Abba Khoushy Ave, Mount Carmel, 3498838 Haifa, Israel

Stress in horses is a multifactorial physiological and psychological response to environmental and management challenges and is particularly relevant in competitive sport settings. Conventional assessment relies on physiological measurements and manual behavioural coding frameworks such as the Equine Facial Action Coding System (EquiFACS), which provides anatomically grounded facial motion descriptions but requires trained coders and is difficult to implement for continuous monitoring. This proof-of-concept study explored whether deep learning models can distinguish relaxed and pre-competition tense states from video recordings and whether a correspondence-based explainability framework (SHIC-XE) can highlight anatomically meaningful regions consistent with EquiFACS-based descriptions and expert-defined regions of interest. Video data collected under baseline and pre-competition conditions were processed using automated detection, segmentation, and transfer-learning-based feature extraction. A supervised neural network classifier was evaluated using leave-one-horse-out cross-validation to assess generalization across individuals. Model performance was quantified using accuracy, precision, recall, F1-score, sensitivity, and specificity at frame and video levels. To improve interpretability beyond conventional 2D saliency maps, gradient-based explanations were projected onto a canonical 3D equine head model via dense 2D–3D correspondence mapping, enabling viewpoint-invariant and temporally coherent aggregation of attention. Regional attention distributions were compared across behavioral states and examined in relation to EquiFACS-informed anatomical regions and expert visual assessment. Preliminary findings suggest that automated classification can differentiate relaxed and tense states under competition-related conditions. Whole-body representations tended to provide stronger discrimination than facial crops alone. Correspondence-based explainability indicated increased attention to supraorbital and auricular regions during tense states, broadly consistent with documented stress-related facial movements. These results provide initial evidence that correspondence-based explainable AI may offer a complementary tool to manual coding frameworks for equine stress assessment and could contribute to future development of transparent decision-support systems in sport horse welfare monitoring.

Fear reactions in cattle, sheep, and horses to potential predator-deterring stimuli: Does a predator stimulus induce fear-enhanced startle in livestock?

U. König Von Borstel[1], C. Schnepp[1], C. Ehry[1], A. Lauth[1], K. Trinkaus[1], S. Lojewski[1], K. Gondolf[1]
[1] University of Giessen, Animal Husbandry, Behaviour and Welfare, Leihgesterner Weg 52, 35392 Giessen, Germany

As large predators increasingly re-emerge in Western and Central Europe human-wildlife conflict becomes more pronounced and effective predator deterrence gains importance. Therefore, the aim of the mAInZaun project was to develop an 'intelligent' fence, that – using artificial intelligence – is able to automatically detect and deter wolves when they approach livestock pastures. However, when predators are deterred from pastures housing livestock, such deterrence stimuli must not be harmful to the livestock themselves. Therefore, the aims of the project were (1) to test the effects of potential predator-deterring stimuli on startle and fear reactions in cattle, sheep and horses and to compare these reactions to reactions to a known startle stimulus and (2) to assess potential fear-enhancing effects of predator stimuli on startle reactions in cattle, sheep and horses. The experiment included three studies, involving 20 cattle, 60 sheep and 20 horses, respectively. Animals were exposed in balanced order to the following potential predator-deterring test stimuli, each presented with and without a predator stimulus (recording of wolf howling): umbrella (serving as a known startle stimulus), strobe light, ultrasound, a scent marketed as wolf-deterrent (cattle only) and spraying from a spray bottle (horses only). Animals were brought to a test compartment either alone (cattle, horses) or in groups of five (sheep). They were allowed a habituation period, were then allowed to feed from a trough with concentrates and were then exposed to the startling stimuli while feeding. The intensity of startle and fear reactions was measured via a behaviour score, latency to resume feeding, heart rate (sheep and horses), heart rate variability (horses) and thermal images of the eye (cattle). Additionally, behaviour patterns such as vocalisations, elimination and freezing were recorded. As expected, mixed model analyses revealed numerically stronger reactions to the umbrella in all three species, compared with the other stimuli, although not all pairwise comparisons were significant (e.g. cattle, umbrella-strobe light: $P>0.1$ for the behaviour score), indicating that some of the potentially wolf-deterring stimuli should only be used after habituation of livestock to these stimuli. For the majority of parameters and stimuli, presentation of the wolf stimulus alongside the test stimuli did not result in greater startle reactions. However, sheep showed significantly greater startle reactions to the strobe light and the umbrella, when these were presented with rather than without predator stimulus (score: $P<0.05$). Cattle tended to react mores strongly to the scent and the ultrasound and also tended to have higher eye temperatures when presented with rather than without the predator stimulus (all $0.05<P<0.1$). For horses, no such clear trend regarding the predator stimulus was observed. Results indicate that, while livestock reacted to the predator-deterrence stimuli with startle and fear reactions, reactions were generally not pronounced, and habituation should be possible. However, the presence of wolf stimuli may induce fear-enhanced startle reactions, particularly in sheep. Therefore, potentially wolf-deterrent stimuli intended for use in livestock pastures should not only be tested in isolation for potentially harmful effects on livestock, but also in combination with predator stimuli to better mimic real-life situations.

How can we effectively improve the welfare of broiler chickens in commercial production systems? A review of farming practices and their relationship with broiler welfare

I. De Jong[1]
[1] *Wageningen Livestock Research, Animal Welfare and Health, De Elst 1, 6708 WD Wageningen, Netherlands*

With growing attention to sustainable farming practices, broiler production systems are becoming increasingly diverse and often adopt a range of welfare promoting management strategies. Several countries have already undergone a national transition toward systems that promote higher broiler welfare, each country implementing its own set of requirements. A broader shift at the European level is also expected, for example through the uptake of the European Chicken Commitment by food businesses. Higher-welfare broiler production systems differ substantially in their specifications, ranging from indoor systems with relatively small reductions in stocking density and some environmental enrichment to highly extensive systems that include outdoor access and the use of slow-growing strains. For some of the management measures commonly applied in commercial higher-welfare systems, a substantial body of research is available to support the choices made, particularly regarding reduced stocking density and the use of slower-growing broiler strains. However, for other measures, such as early post-hatch feeding, specific lighting programs, the combination of different enrichment types or a covered veranda, as well as practices related to catching and transport, scientific evidence is more limited. Moreover, interactions between these factors and key variables such as stocking density or breed remain poorly understood, e.g., whether fast- and slow-growing strains have different requirements or responses to the environment. This presentation will evaluate key management approaches frequently used in higher-welfare broiler systems in terms of their effects on broiler welfare and will identify areas where further research is needed. Promising management factors that could be incorporated into future higher-welfare systems will also be highlighted. Because management factors may interact and commercial conditions often differ markedly from those in experimental or small-scale studies, research under controlled conditions must be validated by data collected in commercial practice. Moreover, comparative studies of production systems based on welfare outcomes provide valuable insights that cannot be obtained from experiments focusing on single factors. We will illustrate this with examples of system comparisons with respect to broiler welfare outcomes. Finally, we will consider whether current higher-welfare broiler systems not only reduce negative affective states but may also promote positive affective states by offering birds greater choice and rewarding experiences. Potential avenues for future research in this area will be discussed.

Early-life characterisation of temperaments in pullets in relation to subsequent severe feather pecking behaviour

A. Kleiber[1], C. Boulange[1], J. P. Moysan[2], L. Dumontier[3], L. Calandreau[3], V. Hugo Bessa Ferreira[3], A. Foreau[4], M. Quentin[4], V. Guesdon[5], M. Sourdioux[6], M. Guinebretière[1]

Injurious pecking in laying hens has a multifactorial and episodic origin, making its causes difficult to identify and control. Severe feather pecking can cause cannibalism, high mortality, and reduced egg production, with important animal welfare and economic consequences. Beak trimming — the cauterisation of the beak tip using an infrared laser — has long been used to limit the associated damage, but is considered potentially painful and has been banned in several European countries. Notably, bans have been implemented primarily in countries where flocks consist mainly of white egg-laying strains, which are generally less prone to pecking than the brown strains predominant in France. Alternative strategies such as environmental enrichment, light or nutritional management have been studied, but show variable effects and generally only mitigate the consequences of injurious pecking once it emerges. Beyond management factors, individual behavioural traits may also influence susceptibility to injurious pecking. Hens vary in exploration, learning, and stress responses along a proactive–reactive axis: proactive individuals tend to be bold and active, whereas reactive individuals are more cautious and flexible. Proactive traits have been associated with higher feather-pecking propensity and appear partly heritable, suggesting that temperament may play a role in pecking behaviour. Yet the full behavioural profile of hens in relation to their pecking propensity remains poorly understood. We thus aimed to determine whether behavioural – proactive or reactive – traits in pullets predict later occurrence of injurious pecking. A total of 200 ISA Brown hens were monitored under commercial-like conditions. A battery of behavioural tests was conducted at two pullet stages (5–7 and 12–15 weeks) and at the onset of lay (17–21 weeks) to assess temperamental traits, based on tonic immobility, attention bias, social motivation, emergence, and food perseverance tests, alongside individual in situ activity (29 observation days x 3 scans per day, totalling 69 scans) and body weight. Severe feather pecking during the laying period was recorded for each hen during two daily 15-minute sessions over 33 days (weeks 30-36), and used to classify individuals as high, moderate or low peckers. The relationship between this classification and early-life behavioural profiles is investigated to identify profiles associated with a higher propensity for pecking. Data analyses are ongoing and will be finalised for presentation. Early behavioural predictors could support development of screening tools for farmers to implement preventive measures from the pullet stage onwards.

Effects of drinking water optimization on immune, physiological welfare parameters, egg quality, and productivity in laying hens

Y. Wein[1], M. Subhi[1], S. Rubin[1], S. Mabjeesh[1], I. Yoselevitz[2], K. Shmuel[3], A. Friedman[1]
[1] The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem, Animal Sciences, POB 12, 76100 Rehovot, Israel, [2] Ministry of Agriculture, Shaham Poultry Division, POB 82, 50250 Beit Dagan, Israel, [3] Katz–Beerotayim Poultry Farm, HaNakhalim 32, 4291500 Be'erotayim, Israel

Maintaining physiological stability (homeostasis) is essential for animals' survival. Accordingly, any event that disrupts homeostasis is defined as stress and poses a threat to survival, and coping with this threat and restoring physiological stability requires substantial physiological resources. Restoration of homeostasis is made possible by the synergistic activity of many physiological systems, among which the immune system is one of the main and most important. Animals raised under intensive farming conditions are exposed to many stressors. For several years, our laboratory has been developing a minimally invasive method for measuring stress, in order to provide reliable and quantitative markers of stress experienced by animals during rearing. The need for such a method arose for two main reasons: first, concern for animal welfare, as the method makes it possible to identify stressful management conditions with the aim of improving them; and second, the need to detect stressful management conditions that may impair animal performance during rearing. To date, the method has been applied to measuring stress in chickens (layers and broilers) and turkeys under various management conditions, such as stocking density, molting, feed withdrawal, transportation, and marketing. Here, using the same methodology, we sought to assess the stress status of commercial Lohmann laying hens under two watering systems (treated water versus tap water). Two hundred layers were housed in eight community cages. Each cage contained 25 hens at a stocking density of 750 cm² per hen. Half of the cages received treated water (acidified and chlorinated) and the other half received untreated tap water; water and feed were available ad libitum. The experiment consisted of three biological replicates. Each replicate began with a 3-week recovery period, followed by allocation to groups, blood sampling after 3 weeks of treatment, and then repetition of this sequence. In each biological replicate, blood was sampled from 15 different hens from each treatment group. We found that while there were no changes in physiological parameters such as hematocrit and total protein, there was a significant ($p<0.05$) decrease in oxidative-active metabolites (AGEs) and in the antioxidant protein lysozyme serum levels, as well as a decrease in pro-inflammatory cytokines IL-6 and IL-1β and stress-related markers Heat Shock Protein 70 (HSP-70) and glucocorticoid receptor (GCR) gene expression in peripheral blood leukocytes (PBLs) in the treated-water group. Additionally, a reduction in pathogenic bacterial burden in the drinking water, alongside improvement in most productivity and egg quality parameters, was recorded in the treated-water group. In light of these observations, it appears that laying hens undergo a process of coping with oxidative stress through elevated levels of immune antioxidant metabolites. Moreover, optimizing hens' drinking-water quality seems to have stress-reducing and beneficial effects.

Enhancing laying hen welfare and thermal comfort in cage-free systems using cooled perches.

M. Ross[1], J. D. Mwifunyi[1], A. Haron[1], D. Bachrach[2], S. Druyan[1]
[1] Agricultural Research Organization, Animal Science, 68 Derech Hamaccabim, 7505101 Rishon Lezion, Israel, [2] Ministry of Agriculture and Food Security, Shaham, Extension Service, 68 Derech Hamaccabim, 7505101 Rishon Lezion, Israel

Housing conditions are critical determinants of laying hen welfare. While conventional cages restrict natural behaviors and impair skeletal health, cage free systems allow expression of natural behaviors but introduce problems such as feather pecking and keel bone injuries. Environmental enrichment in cage-free systems, particularly perches, is essential for enabling natural resting behavior, reducing aggression and supporting bone strength. This study investigates an innovative approach to improve the thermal comfort, health, and welfare of laying hens within cage-free systems. We evaluated the efficacy of cooled perches in aiding thermal regulation in laying hens during periods of intense heat stress. The study was conducted over the summer months (July-September) in an experimental cage-free system, and involved 50 laying hens housed at a density of 7 hens/m². The pen was equipped with feeders, drinkers, laying nests and two sets of perches elevated 70 cm above the littered floor. One set was actively cooled to 24°C using circulating water. Following an initial adaptation period, the pen was divided into two sections, with each section containing one type of perch. To gather physiological data, internal data loggers were implanted in 24 hens (12 per group), continuously recording core body temperature in 20 hens, and both temperature and heart rate in 4 hens. Behavioral observations were captured via continuous video recording, supplemented by intermittent thermal imaging to measure feet temperatures on both cooled and control perches. Throughout the experiment, high environmental temperatures and humidity were recorded, creating significant heat stress, making the study highly relevant to real-world challenges. The cooled perch system consistently maintained its target temperature of 24°C. Our physiological data revealed that laying hens with access to cooled perches consistently exhibited lower core body temperatures (0.3-0.5°C cooler) and more stable thermal profiles compared to hens in the control group. This indicates efficient heat conduction from their feet to the cooled perches. Behavioral analysis from video recordings further supported these findings: hens in the cooled perch group spent significantly more time on the perches, particularly during hot afternoons and evenings, demonstrating a clear preference and enhanced comfort. In contrast, control group hens tended to cluster on the litter. The even distribution of hens on the cooled perches suggested genuine thermal relief, unlike the control group where hens gathered near drinkers, likely seeking water to cope with the heat. Thermographic imaging provided visual evidence, showing lower contact temperatures (≈27–29°C) on cooled perches compared to control perches (≈30–31°C), coupled with reduced foot temperatures, underscoring the effectiveness of heat transfer. Laying rates were similar in both groups and were not affected by the cooled perches. The findings of this study demonstrate that cooled perches significantly enhance both the thermal welfare and behavioral comfort of laying hens in hot climates. By providing an effective mechanism for heat dissipation, cooled perches offer a viable and sustainable solution for managing heat stress, promoting better health outcomes, and ultimately improving the overall welfare of laying hens in cage-free poultry farming systems and specifically in houses without thermal regulation.

Welfare indicators during the early rearing period – Comparing young birds of dual-purpose and layer hybrid genotypes under organic conditions

H. Pluschke[1], D. Werner[1]
[1] Thuenen Institute of Organic Farming, Trenthorst 32, 23847 Westerau, Germany

Dual-purpose chicken genotypes (DPG) are considered a more ethical alternative to intensive layer and broiler systems, being more robust with good welfare performance. However, most welfare evaluations are conducted at the end of the fattening or during the laying period and little attention is paid to the rearing period. This phase is a critical developmental window, where early-life conditions have lasting impacts on health and productivity. Understanding welfare development during this period is essential for designing management strategies that support high standards throughout the production cycle. In this context, we investigated two DPG (Coffee, Cream) and one layer hybrid (ISA Warren) from hatch to 6 weeks of age (woa) under organic conditions (approval no. IX552-105434), assessing genotype-, sex-, and age-related differences in welfare indicators. Chicks of Coffee (COF n=333) and ISA Warren (WA1 n=352) hatched in October 2024, and Cream (CRE n=353) and ISA Warren (WA2 n=345) in November 2025; each was individually wing-tagged at placement. Two weeks later, each genotype was split into even numbered, mixed-sex groups. Birds were reared on deep-litter floors with perches, provided maize silage, dustbaths, and a lactic acid supplement, with access to a covered veranda from 4 woa. Organic feed was supplied according to standard nutrient requirements, alongside standard lighting, temperature, and vaccination protocols. Welfare indicators were assessed at 2/3 and 6 woa using the MTool protocol, covering 14 body regions on an ordinal scale (0–2), and birds were weighed at each assessment. BW and welfare scores were analysed using a general linear model with Tukey and Bonferroni adjustments respectively, including genotype, age, sex, and their interactions as fixed effects, with wing band as random effect. DPG exhibited higher growth performance than the layer hybrid. At the end of the mixed-sex rearing period at 6 woa, BW was highest in COF (791g), followed by CRE (599g), WA1 (518g), and WA2 (467g). Sex significantly affected BW, with the largest male–female differences observed in the DPG (CRE 22%, COF 20%) and the smallest in WA2 (17%), indicating stronger sexual dimorphism in DPG already evident in early BW development. Despite these growth differences, genotype effects on welfare were not uniform across indicators. Only three out of 14 welfare indicators – pecked and used wing feathers as well as footpad health – consistently differed between genotypes, with WA1 and COF showing the best outcomes. For pecked and used wing feathers, a significant sex*week interaction was observed, whereas sex alone had no effect. Pecked feathers on the tail or back showed a significant genotype*age interaction, with CRE having increased scores at 3 woa that resolved by 6 woa. Footpad health was influenced by both genotype and age, with WA2 showing the poorest outcome. Age, and its interaction with sex or genotype, significantly affected several welfare indicators, emphasizing the importance of age-specific management during rearing. In contrast, genotype effects were indicator-specific and generally less consistent across the tested genotypes. Behaviour-related influences on indicators can emerge during the rearing period, locomotor activities such as perching and exploration should be encouraged and guided to support healthy development. The results demonstrate that welfare in young chickens is dynamic and shaped by interacting effects of age, genotype, and sex. Understanding how welfare parameters change over time can improve management strategies that consider both genetic background and rearing conditions, laying the foundation for healthy, robust, and resilient chickens.

Precision farming practices for sustainable poultry production in the USA

L. Chai[1]
[1] *University of Georgia, Poultry Science, 120 DW Brooks Dr, 30602 Athens, United States*

The global population is predicted to reach over 9.5 billion in 2050, by then the requirement for animal protein (e.g., eggs, meat, and milk) will increase by over 70% as compared to 2005. Providing food for the increasing world population with limited natural resources is a grand challenge for animal agriculture. The animal farming systems in U.S. play a key role in feeding the increasing world population. According to USDA, the total US poultry sector sales in 2025 were close to $90 billion (e.g., 9.3 billion broiler chickens and 100 billion table eggs), which ranks the US one of world's largest poultry and egg production countries. Despite this productivity, concerns remain regarding animal welfare and environmental conditions in poultry production systems. Fast-growing broiler chickens frequently experience welfare issues, with about 30% suffering from leg problems and over 50% developing footpad lesions. In egg production systems, cage-free laying hens have been reported to experience nearly double the mortality and injury rates compared to hens raised in conventional cage systems. Additionally, air quality challenges in cage-free housing systems continue to raise concerns for both animal welfare and worker health. To improve sustainability and address these issues, precision animal farming technologies are increasingly needed. In this study, artificial intelligence (AI)–based technologies, including machine vision and robotics, were developed to monitor and manage poultry health and welfare. These advanced systems achieved over 90% accuracy in detecting conditions such as footpad dermatitis, bumblefoot, and bird mortality. Furthermore, large foundation models such as SAM (Segment Anything Model) and TAM (Track Anything Model) were effectively applied for individual bird tracking and locomotion speed monitoring. For improving air quality management, electrostatic airspace charging systems and electrolyzed water sprinklers were designed and evaluated in commercial cage-free houses, demonstrating promising control efficiency.

A novel method to evaluate the social impact of livestock systems: a social life cycle assessment of the impacts of the Irish pig value chain

C. Wangui[1], G. Carroll[2], I. Kyriazakis[1]
[1] Queen's University Belfast, School of Biological Sciences, 19 Chlorine Gardens, BT9 5DL Belfast, United Kingdom, [2] Queen's University Belfast, School of Psychology, David Keir Bldg 18-30 Malone Rd, BT9 5BN Belfast, United Kingdom

The social sustainability pillar of livestock systems is the most commonly overlooked amongst the three pillar of sustainability. Social Life Cycle Assessment (S-LCA) is widely used to evaluate social sustainability, yet its application to the assessment of social impacts in agri-food systems has notable limitations. These include reliance on social performance assessments, lack of sector-specific activity variables and use of linear reference scoring, which can distort the representation of social impacts in such systems. We developed an enhanced S-LCA framework that integrates social risks and hotspots with social performance, incorporates added-value activity variables tailored to agricultural systems and replaces linear scoring with contextualized nonlinear scores. The Irish pig value chain is used as a case study. We added pigs as a Stakeholder category, alongside existing Stakeholders of S-LCA. Performance reference points (PRP)and inventory indicators were derived from national and regional pig industry benchmarks. Social performance was evaluated by comparing each indicator with its corresponding PRP and assigning an ordinal score. These ordinal scores were converted into cardinal through expert judgement to enable nonlinear scoring. Both ordinal (linear) and cardinal (nonlinear) scores were transformed into social risk values (S_i) using reversed min–max normalization, such that $0 < S_i < 1$, where a value of 1 represented extreme social risk. Adapted time-based added-value activity variables (A_i) were defined for stakeholder groups as follows: “people days” for the local community and society, “consumption days” for consumers, and “pig life days” for pigs. Impact sub-categories were ranked by experts, and their relative weights (W_i) were derived using the Analytic Hierarchy Process. Social risk time (SRT_i) for each inventory indicator was calculated as $S_i \times A_i \times W_i$ and expressed as a percentage relative to the aggregated value for each stakeholder group. Social hotspots were estimated using SRT_i / SRT□, where SRT□ corresponded to the case where S = 1. Social risks (S) were highest for pigs (0.57 vs. 0.64) and lowest for society (0.47 vs. 0.44) under the linear and nonlinear methods, respectively. The SRT differed between scoring approaches across all stakeholder groups. Linear scoring overestimated overall SRT for society (3.5%) and consumers (67.0%) and underestimated SRT for the local community (4.7%) and pigs (11.1%). Both methods identified the pig farm (0.57 vs. 0.65) and local community (0.52 vs. 0.55) as social risk hotspots and the consumption stage (0.39 vs. 0.31) as a social opportunity hotspot. The linear scoring method showed systematic bias in estimating social risk, whereas incorporating contextualization in the non-linear scoring produced more nuanced and granular results across all stakeholder groups. This implies that linear scoring tends to misrepresent social issues in pig value chains because it applies a uniform scale to all performance levels. The proposed methodology highlights the importance of assessing social risks and hotspots alongside social performance in agricultural S-LCA. Incorporating time-based value-added activity variables specific to agricultural system and developed for each stakeholder group improves the representation of exposure duration to social issues and more accurately reflects how value-chain processes shape social impacts. The study also demonstrated the advantages of nonlinear scoring over the linear method.

Impact of animal welfare on milk production and economic performance in dairy farm

M. Alrhmoun[1], T. Zanon[1], M. Gauly[2]
[1] Free University of Bolzano, Piazza Università,1, 39100 Bolzano, Italy, [2] University of Veterinary Medicine, Veterinärplatz 1, 1210 Vienna, Austria

Animal welfare is increasingly recognized as a key component of sustainable livestock farming, yet its quantitative contribution to production efficiency and farm profitability remains insufficiently documented. This study assessed the relationship between animal welfare, milk production, and economic performance in dairy farms using a farm-level quantitative approach. A total of 169 dairy farms were evaluated using the ClassyFarm protocol, which integrates animal-based, resource-based, and management indicators into a composite welfare score. Farms were classified into low (<50), medium (51–60), and high (61–81) welfare categories. Milk yield, somatic cell score, milk quality traits, and energy-corrected milk (ECM) were analyzed in relation to welfare level, housing system, breed, herd size, and access to grazing. Multivariable regression models were applied, and causal effects of higher welfare standards were estimated using regression adjustment and augmented inverse probability weighting (AIPW). Farms with higher welfare scores showed significantly higher milk yield and ECM, alongside lower somatic cell scores, compared with low-welfare farms. Free-stall housing and access to grazing were positively associated with ECM, while breed-specific responses highlighted differences in performance under varying welfare conditions. Causal estimates indicated that adoption of higher welfare standards increased ECM by approximately 1.8–2.0 kg per cow per day, corresponding to an additional economic return of 3.2–3.6 € per cow per day. These results demonstrate that improved animal welfare contributes positively to both production efficiency and economic sustainability in dairy farming systems. Integrating welfare-oriented management strategies can therefore enhance farm resilience and profitability while supporting a more sustainable livestock sector.

From live animal export to meat and carcass trade: economic, sustainability, and welfare perspective

E. Massalin[1], S. Blattner[1], B. Guesmi[2]
[1] Eurogroup for Animals, Farm Animals Team, 29 Rue Ducale, 1000 Brussels, Belgium, [2] Centre de Recerca en Economia i Desenvolupament Agroalimentari UPC-IRTA (CREDA), Esteve Terradas Street 8, Castelldefels, 08860 Barcelona, Spain

Long-distance live animal transport continues to raise significant animal welfare, environmental and public health concerns. Drawing on a comparative cost-benefit trade modelling framework, this study demonstrates that transitioning to meat and carcass trade is economically feasible, reduces the environmental footprint associated with long-distance transport, and strengthens the competitiveness and resilience of the EU agri-food sector. The study synthesises evidence from two completed analyses—a Portugal-Israel trade case (sheep) and a Romanian live export assessment (bovine and ovine)—and two ongoing projects—unweaned calf transport from Ireland to Spain, and lamb exports from Romania to Italy. For each case study, two scenarios are evaluated: long-distance live animal export and meat and carcass trade. Key indicators include: transport duration and costs, mortality and morbidity, abattoir throughput, value-added retention, fuel consumption and CO_2-equivalent emissions, including cold-chain logistics. Scenario outcomes are compared across economic, welfare, and environmental dimensions to assess the feasibility and impact of transitioning to carcass-based trade. The economic modelling indicates that carcass trade can offer structural and economic advantages. In the Portugal-Israel case, exporting carcasses was estimated to cost nearly 2.5 times less per kg than live animals, while enabling higher utilisation of domestic slaughter capacity and retention of value-added processing within the EU. Romanian modelling suggests that phasing out live exports could generate approximately 5,300 jobs and €46 million in gross value added. Environmental assessment indicates lower impacts under carcass trade scenarios. In the Portugal-Israel case, CO_2-equivalent emissions per kg were almost 6 times higher for live transport, with fuel consumption similarly elevated. Shorter journeys reduce stress, morbidity, and mortality, thereby mitigating risks of transmissible diseases and associated economic losses. Indeed, EFSA (2002) has noted that poor welfare and prolonged transport increase susceptibility to disease, highlighting the association between transport duration and animal health risk. This emphasises the One Health interface between animal, human, and environmental health. Transitioning to meat and carcasses trade represents a feasible alternative and solution. Regarding the ongoing case studies, preliminary results for the Ireland–Spain route suggest that shifting from live calf exports to domestic processing and meat export reduces emissions (33.7 vs 35.1 kg CO_2e/kg meat). While economic cost remains higher (€6.77/kg vs €10.31/kg), this gap is expected to narrow with refined feedlot and processing assumptions. Animal welfare outcomes strongly favour meat export, as live export entails prolonged transport, increased stress, multiple handling events, sea crossing, and substantial live weight loss. Emerging policy developments and broader sustainability constraints—including Ireland's nitrate derogation and herd intensity limits—further challenge the long-term viability of the current system. In this context, shorter transport distances and carcass-based trade models may reduce emissions, operational vulnerability and disease transmission risk. Overall, integrating economic modelling with welfare, environmental, and policy analysis demonstrates that the transition from live animal exports to meat and carcass trade could represent a feasible alternative under current market and regulatory assumptions.

Assessment of carcass and meat quality of crossbreeds of local breeds and commercial lines under organic feeding regime containing alfalfa

W. L. Oo[1], Z. Bodor[1], M. Krieger[2], D. Mörlein[1]
[1] University of Göttingen, Department of Animal Sciences, Product Quality of Animal Products, Kellnerweg 6, 37077 Göttingen, Germany, [2] University of Kassel, Section Farm Animal Behaviour and Animal Husbandry, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany

Local chicken breeds are valuable genetic resources for sustainable poultry production. They are adaptive to local environments but low in production performance. Nowadays, organic poultry products are preferred by consumers due to food safety under environmentally friendly production practice. Crossing local breeds with commercial lines possessing improved production performance is one of the solutions for sustainable poultry production and for conservation of valuable genetic resources. Use of local breeds in organic farming will promote their potential for economic relevance. In organic farming, it is not allowed to use artificially synthesized growth promoters and amino acids. Alfalfa, a locally available feed, is rich in essential amino acids, and can be considered as a feasible organic feed source. The present study was aimed at determining carcass and meat quality of crossbreeds fed organic diets containing sieved alfalfa. Three German, local chicken breeds, Altsteirer (ALT), Ramelsloher (RAM), Bielefelder (BIE) were crossed with commercial lines, layers (White Rock, WR) and broilers (Ranger, RG). The birds were fed organic diets containing alfalfa meal (5%) until week 12. Two dietary feeding regimes: control diet (5% alfalfa) and trial diet (15% alfalfa) were used in week 13-14, and the alfalfa was increased to 20% in the trial diet in week 15-18. At week 14, 16 and 18, 10 birds per cross per diet (n=360) were slaughtered to determine carcass and meat quality parameters. Data were analyzed in R using parental lines, diets and age as factors fitted in a linear mixed model. It was hypothesized that crosses of commercial broilers will be better in carcass and meat quality under this organic feeding regime. Across all ages, carcass and meat quality parameters were mostly influenced by mother lines. RG crosses possessed higher ($p<0.01$) carcass, breast and thigh weight than WR crosses. In terms of meat quality, there were lower storage loss (SL), cooking loss (CL) and shear force (SF) in RG compared to WR crosses. Higher Inosine 5′-monophosphate (IMP) and creatine contents were investigated in RG crosses. The fatty acid contents (SFA, MUFA, PUFA) were higher ($p<0.01$) in WR crosses. Among father lines, carcass weight in weeks 14 and 18 were higher ($p<0.001$) in BIE crosses (1,089 and 1,616 g) compared to ALT (1,029 and 1,566 g) and RAM (1,006 and 1,520g). IMP of ALT crosses was lower ($p<0.001$) than BIE and RAM at week 14. Inosine of RAM crosses was higher ($p<0.05$) than BIE crosses while ALT crosses were similar to both at week 18. BIE crosses had higher ($p<0.05$) SFA than ALT at week 14 and higher ($p<0.05$) n-6 PUFA than RAM at week 18. Regarding the diet, there were no significant different effects of diets, except higher carcass weight in the control at weeks (16-18). In chemical composition, crosses in the trial diet were lower ($p<0.05$) in IMP and inosine at week 18, but higher in MUFA and n-3 PUFA across ages. According to age groups, crosses at week 16 had higher ($p<0.05$) in SL of breast, lower ($p<0.001$) CL of breast and thigh than those at week 18. Overall findings reflected the genetic potential of parental lines in crossbreeding. RG and BIE crosses demonstrated higher carcass and better meat quality. No significant effects of diets highlighted the contribution of dietary alfalfa meeting nutrient requirements of crossbreeds, except carcass weight at weeks 16-18. RG and BIE crosses have been shown to be most suitable for high-quality carcass production under organic feeding regimes.

The effect of broiler production system on carcass quality

R. Van Emous[1]
[1] *Wageningen Livestock Research, Animal Nutrition, De Elst 1, 6708 WD Wageningen, Netherlands*

The Dutch broiler sector is rapidly transitioning toward production systems based on slow-growing genotypes. Despite their increasing market share, scientific knowledge specific to slow-growing broilers, particularly regarding carcass quality, remains limited. Most existing insights originate from studies on conventional fast-growing broilers, leaving key gaps in understanding resource efficiency, behaviour, health, environmental sensitivity, and slaughter outcomes in slower-growing broiler production systems. This study therefore evaluated the effects of season, catching method, and thinning on carcass quality and production parameters across four broiler production systems in the Netherlands. Slaughterhouse data collected from 2018 to 2020 included conventional fast-growing broilers (CONV; n=14,976 flocks), two indoor slow-growing broiler systems (SGB1; n=1,730 and SGB2; n=3,713), and the Better Life 1-Star broiler system (BLS; n=1,121). Mixed-model (REML) analysis was used to estimate the fixed effects of season (via Fourier transformation), production system, slaughter location, and catching method, as well as random coefficients for carcass quality traits. Across all slow-growing systems, slaughter weight and average daily gain (ADG), first-week mortality, and total mortality were consistently reduced than in CONV broilers. SGB1 showed higher ADG than SGB2 and BLS. Seasonal patterns were evident: slaughter weight and ADG were lowest for chicks placed in March/April and highest for those placed in September/October. All slow-growing systems (SGB1, SGB2, and BLS) demonstrated improved welfare and carcass quality outcomes, including reduced footpad lesions, hock burns, leg and breast hematomas, dead-on-arrival birds (DOAs), and total carcass rejects compared than CONV broilers. Season influenced lesion patterns, with autumn flocks showing more hock burns, footpad lesions, and wing hematomas than spring flocks. Summer flocks had more scabby hips but fewer total rejects relative to winter flocks. Thinning was associated with more scabby hips, ammonia burns, and DOAs, but fewer other lesion types and carcass rejects compared with non-thinning flocks. Mechanically caught flocks had more ammonia burns, DOAs, and total rejects than manually caught flocks. In conclusion, this large-scale analysis demonstrates that slow-growing broiler production systems consistently achieve lower mortality and improved welfare-related carcass quality indicators compared with conventional fast-growing systems. Seasonal and management factors significantly modulate these outcomes, underscoring the need for system-specific optimisation as the sector transitions toward slower-growing broiler production.

Genetic characterization of Extremeña Azul, an endangered native Spanish chicken breed, using 30 microsatellites markers

M. R. Maya[2], L. Borreguero[1], Á. Trigo[2], I. Bonet[2], J. L. Gala Bayón[3], P. Valera[4], J. A. Bouzada[1]
[1] SG de Laboratorios de Sanidad Animal y Vegetal, Identificación Genética, Ctra. M-106, Km 1,4, 28110 Algete (MADRID), Spain, [2] TRAGSATEC, Tecnología y Servicios Agrarios, Julian Camarillo, 5, 28037 MADRID, Spain, [3] ACGEXA, Asociación de Criadores de Gallinas de Raza Extremeña Azul, Macarena 1-1D, 06200 Almendralejo (BADAJOZ), Spain, [4] GESCAN, Gestión de programas de cría, S.L., Avda. Practicante Ignacio Rodríguez s/n Parque tecnológico de GC, 35017 Las Palmas de Gran Canaria, Spain

Poultry biodiversity is considered one of the most endangered genetic resources considering the general loss of genetic variability in highly selected species. Commercialization of chicken breeding favored the use of highly productive chicken breeds and consequently led to lower population sizes of low performing native breeds. Aware of the importance of preserving native breeds, Regional Government of Extremadura launched a recovery program of Extremeña Azul breed based on a few existing animals which currently numbers around 2,300 individuals of 54 different breeders. Molecular markers are essential for genetic management to ensure high accuracy in breeding and conservation programs. Laboratorio Central de Veterinaria (Madrid) proposes two multiplex PCR to analyze the thirty microsatellite markers (ADL0112, ADL0268, ADL0278, LEI0094, LEI0166, LEI0192, LEI0234, MCW0014, MCW0016, MCW0020, MCW0034, MCW0037, MCW0067, MCW0069, MCW0078, MCW0080, MCW0081, MCW0098, MCW0103, MCW0104, MCW0111, MCW0123, MCW0165, MCW0183, MCW0206, MCW0216, MCW0222, MCW0248, MCW0295 and MCW0330) recommended by the joint ISAG/FAO Standing Committee for the genetic characterization of chicken breeds. Changes in primers were required to achieve a final configuration allowing all markers, in each PCR multiplex, to be analyzed together. Data from 246 samples analyzed show that proposed microsatellites were all well-coamplified in chicken blood samples and were all polymorphic, obtaining an average number of 4.97 alleles per marker (4.70 in males and 4.80 in females). Number of alleles ranged from three markers showing only two alleles (MCW0098, MCW0103 and MCW0248) to one marker with eleven alleles (MCW0104) and another with ten (LEI0234). Mean heterozygosity was 0.6089 and PEG greater than 99.9999%. Data obtained of microsatellite markers used in this study can help to manage breeding programs, as well as planning future crossing programs.

Assessing the feasibility of physical enrichments for guinea fowl (Numida meleagris): A combined behavioural and economic analysis

V. Caprarulo[1], T. Bernardo[1], S. Gabriele[1], G. Traversi[1], S. Carè[2], V. Lorenzi[1], L. J. Vinco[1], L. Bertocchi[1], F. Fusi[1]
[1] IZSLER, Via Bianchi, 9, 25124 Brescia, Italy, [2] CREA, Borgo XX Giugno, 74, 06121 Perugia, Italy

In intensive poultry systems, lack of environmental stimuli can impair animal welfare. Environmental enrichment is a proposed mitigation strategy, but its effects in guinea fowl (Numida meleagris) remain unexplored. This study, part of European Partnership on Animal Health and Welfare (EUPAHW), aims to quantify guinea fowl interactions with enrichments under commercial conditions and assess economic implications. Before the case study, an extensive literature review (Web of Science) was carried out to assess existing experimental protocols and guide the study design. The search terms used were: (guinea fowls OR broiler) AND (enrichment) AND (animal welfare). A systematic literature search identified 2,310 records. After removing duplicates (n=279), records were excluded based on year (n=1,506), language (n=17), article type (n=126), and irrelevant outcomes/topics (n=622), yielding 39 eligible studies from databases. Manual reference screening added 8 studies, resulting in 47 studies included to inform the study design. The study analysed video footage collected during three production cycles (1–80 days) conducted in 2024 at a commercial guinea fowl farm in Italy, with 12,000 guinea fowls per cycle. In each cycle, enrichments (bamboo canes, coloured plastic bottles, egg trays, straw bales, and CDs) were placed in different areas of the pen. The ethogram includes pecking, rubbing, jumping/onto, and other contact. Through focal-animal sampling, the frequency and duration of behaviours were recorded continuously for 5 minutes at two timepoints for one day in weeks (AM/PM). Six cameras per cycle recorded focal pens, with details on placement, height, and filming schedule. From 447 recorded videos, 190 were selected for behavioural analysis; 257 were excluded due to poor quality or insufficient duration. Cycle 2 was entirely discarded as recordings lasted only a few seconds. Cycle 1 contributed 96 usable videos recorded from 24 May to 2 August, distributed across six focal pens with different enrichment combinations. Cycle 3 contributed 94 usable videos recorded from 12 September to 29 November, distributed across five focal pens with various enrichment combinations. The recorded videos will be analysed by the Behavioural Observation Research Interactive Software (BORIS, v 9.7.1). Housing and management data were collected, including stocking density, cycle duration, barn characteristics, and technical equipment. Production parameters such as mortality, live weight, feed conversion ratio, and water consumption were recorded, along with labour inputs and detailed economic costs (feed, health care, energy, litter, and enrichment). All data will be analysed to compare production costs per kg of meat between a baseline scenario and the enrichment scenario derived from the case study. This study presents a methodological framework for evaluating environmental enrichments in commercial guinea fowl farming. The literature review informed the development of the experimental protocol and ethogram. Work is currently in progress: video analysis using BORIS software and economic calculations are being carried out. Final results will provide insights into the welfare and economic implications of environmental enrichments for guinea fowl production systems. This work was co-funded by the European Union's Horizon Europe Project 101136346 EUPAHW. Feather pecking in laying hens: redirected foraging meets a neuroimmune–microbiome gut–brain feedback loop

A. Harlander[1], A. L. Nicklas[1], N. Van Staaveren[1]
[1] University of Guelph, Animal Biosciences, 50 Stone Rd E, N1G 2W1 Guelph, Canada

Feather pecking (FP) remains one of the most consequential welfare challenges in commercial pullets and laying hens worldwide. Uniquely, FP is both an indicator and a cause of compromised welfare and persists across housing systems. Its expression is context-dependent and intermittent, emerging in some individuals, flocks, or years but not others, consistent with genetically influenced yet not genetically fixed vulnerability and shaped by stress physiology, environment, and the microbiome. This talk integrates two historically separate perspectives into a single process. Ethological view: when hens lack access to the coarse, fibrous, manipulable substrates they are biologically motivated to forage for, this unmet need functions as a stressor. Birds forage further and redirect pecking toward feathers as a specific appetitive substrate, a pattern observed even with outdoor access when nutritional/sensory needs remain unmet. Ingested feathers act as a physiologically meaningful resource by increasing gut motility and mimicking some benefits of coarse fibre; they can also foster beneficial Lactobacillus communities, a clue to why foraging-rich environments may reduce FP risk. Dysfunctional view: repeated stressors, nutritional, social, early-life, or chronic, then alter gut microbial composition and metabolites, shifting neuroimmune–microbiome gut–brain signalling. FP phenotypes often show lower Lactobacillus abundance and dysmotility in the gut, and tryptophan-metabolic shifts. Targeted pre-and probiotc-based diets can modulate immune–metabolic crosstalk, increase circulating tryptophan, and alter FP and feather damage, indicating that microbial manipulation can modulate gut–brain communication in susceptible hens. This integrated framework links stressors to physiological, genetic, and behavioural factors that together shape welfare outcomes and potentially explain why FP flickers on and off across flocks and years. It also points to actionable prevention beyond beak trimming: (1) probiotic/prebiotic strategies to stabilize neuroimmune pathways; (2) foraging-rich diets and substrates; (3) early-life enrichment to build stress resilience and behavioural flexibility; (4) strain-aware selection and management to reduce susceptibility; and (5) integrated monitoring that pairs behaviour with microbiome, immune, and stress-physiology indicators. Feather pecking may start for different reasons, such as unmet foraging needs or exposure to other stressors, but it continues once stress disrupts the gut, the microbiome, the immune system, and the brain. These systems then reinforce each other in a loop that maintains the behaviour. Recognizing this loop potentially help us design more effective, long-lasting prevention strategies.

Keel bone damage of local German chicken breeds and their crosses with high performing laying hens

N. Götzke[1], A. Weigend[1], C. Reimer[1], J. Geibel[1], A. R. Sharifi[2], S. Weigend[1]
[1] Friedrich-Loeffler-Institute, Institute of Farm Animal Genetics, Höltystrasse 10, 31535 Neustadt am Rübenberge, Germany, [2] Georg-August-University, Department of Animal Sciences, Albrecht-Thaer-Weg 3, 37075 Göttingen, Germany

Keel bone damage (KBD) is a major welfare problem in laying hens, affecting up to 90% of birds in commercial production systems and potentially causing pain and reduced mobility. Local chicken breeds are often assumed to be more robust than high-performing commercial layers with regard to their health, but empirical evidence supporting this assumption is limited. Within the ÖkoGen project, we aimed to develop strategies for preserving three local chicken breeds—Altsteirer (ALT), Bielefelder Kennhuhn (BIE), and Ramelsloher (RAM)—and evaluate them for their suitability in organic farming. Due to their low laying performance, crosses with high-performing White Rock (WR) hens were also produced. The aim of this study was to compare keel bone damages in purebred hens and in their crosses. Two longitudinal X-ray studies were conducted to assess KBD in purebred hens (28 BIE, 38 ALT, 45 RAM) and crossbred hens (50 each of BIE x WR, ALT x WR, and RAM x WR). Birds were housed in an aviary system from 18 to 72 WoA. Radiographs were taken repeatedly at certain ages (purebreds: 18, 34, 41, 50, 60 and 70 WoA; crosses: 18, 24, 35, 40, 50, 60 and 70 WoA). Individual laying performance was recorded daily throughout this period. Keel bones were divided into cranial, medial, and caudal sections and scored for fractures/calluses on a scale from 0 (no damage) to 3 (severe damage with multiple fractures and dislocations). These scores were combined into a single overall score per bird. KBD scores were analysed using a generalised mixed model based on a Poisson distribution, with observation time included as a polynomial covariate (up to the fourth degree) to account for non-linear age effects, and breed designated as a fixed effect. KBD scores increased significantly with age in both purebreds and crossbreds, with a more pronounced increase observed in ALT than in the other breeds. Among the purebreds, BIE hens showed significantly lower scores than ALT hens, while RAM hens had intermediate scores with no significant differences to BIE or ALT. In the crosses, BIE x WR had significantly lower scores than RAM x WR. RAM x WR hens showed a stronger increase in the KBD scores over time than the other crossbreds. Overall, KBD scores were higher in crossbred hens than in purebreds. In this context it should be noted that crossbred hens also exhibited substantially higher laying rates, nearly twice those of the purebred lines (72–78% vs. 30–39%). These findings indicate that genetic background and production level influence susceptibility to keel bone damage. The substantially higher laying rates in crosses may be associated with their increased KBD, suggesting that both breed and egg production contribute to keel bone health and welfare in laying hens. Our results suggest that local breeds, here Bielefelder Kennhuhn in particular, may improve keel bone stability in high performing crosses. Further analyses will investigate bone mineral density and blood parameters related to calcium homeostasis. The project was supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food (BLE) under the Federal Programme for Ecological Farming.

From performance to footprint: Zootechnical and environmental effects of a protected sodium butyrate supplement in broiler production

B. Saldaña[1], P. Higuera[2], C. Landry[2], M. Panheleux[2]
[1] Novation, C. Marconi, 9, 28823 Madrid, Spain, [2] CCPA France, ZA du Bois de Teillay, Quartier du Haut-Bois, 35150 Janzé, France

The livestock sector is facing increasing societal and regulatory pressure to adopt more sustainable production practices. Within poultry production systems, environmental assessments consistently identify climate change, acidification, and eutrophication as the main impact categories. In this context, protected sodium butyrate (PSB) has gained attention as a functional ingredient with the potential to improve environmental performance. PSB supplementation has been shown to enhance nutrient digestibility, reduce litter moisture and nitrogen excretion, factors that are closely associated with lower ammonia emissions. Together, these improvements in nutrient utilization and performance position PSB as a promising strategy for reducing the environmental footprint of poultry production. This study aims to quantify the contribution of PSB to the environmental footprint of broiler production under Spanish conditions, using a life cycle assessment (LCA) approach with system boundaries defined up to the farm gate. Two comparable broiler production systems were therefore evaluated: a control system and a supplemented system incorporating PSB at a dietary inclusion level of 0.1%. Both LCAs were conducted in accordance with ISO 14040 and ISO 14044 standards and aligned with FAO guidelines for feed additives and poultry supply chains. A cradle-to-farm-gate system boundary was applied, and environmental impacts were assessed using the Environmental Footprint (EF) 3.1 method. Direct manure emissions were modelled following IPCC and EMEP methodologies. Nitrogen excretion was calculated based on measured feed intake, body weight gain, and feed composition. The functional unit was defined as 1 kg of live broiler at the farm gate. The Spanish broiler production system was modelled assuming a 42-days production cycle. Zootechnical experimental data were collected to contribute to the LCA calculations. 400 male broiler chickens were divided into 2 groups: control and PSB which only differed by the addition of the ingredient at 0.1% in feed. Performance (weight, feed intake) and mortality were measured at each stage and in the entire production period. Zootechnical results indicated that PSB supplementation significantly increased final body weight from 2.926 to 3.027 kg per bird (+3.45%, $p<0.05$), while feed consumption remained similar between groups. LCA results showed that the most pronounced relative reductions were observed for Acidification (−4.6%, from 1.51×10^2 to 1.44×10^2 mol H□ eq / kg live weight), Marine Eutrophication (−4.7%, from 6.64×10^2 to 6.33×10^2 kg N eq / kg live weight), Freshwater Ecotoxicity (−3.3%, from 64.01 to 61.91 CTUe / kg live weight), Total Climate Change (−3.1%, from 1.85 to 1.80 kg CO_2 eq / kg live weight), and Water Use (−3.1%, from 1.69 to 1.64 m^3 world eq / kg live weight). In addition, ammonia emissions were reduced by approximately 10.4%, decreasing from 0.000968 to 0.000867 kg NH□/kg live weight modelled mitigation effect. The productivity gains associated with PSB supplementation translated into consistent reductions in environmental impacts per kilogram of live weight produced, with an overall decrease of approximately 3% across impact categories. The reduction in ammonia emissions should therefore be interpreted as a modelled outcome of improved nitrogen utilization efficiency rather than a direct modification of emission factors. Overall, the combined zootechnical and LCA results indicate that PSB supplementation provides a dual benefit by enhancing broiler productivity while simultaneously reducing environmental burdens per unit of live weight produced.

An innovative plant-based solution that helps prevent the negative effect of coccidiosis

A. Juanchich[1], J. Dechaume[1], A. Dupuis[2], J. Le Douce[2], M. Brunon[2], M. Gohin[1], E. Coudert[1]
[1] Centre Mondial de l'Innovation Roullier, 18 avenue Franklin Roosevelt, 35400 Saint Malo, France, [2] IN-NOZH, 2 rue Jean Rostand, 22440 Ploufragan, France

Coccidiosis remains a major challenge in the poultry industry, significantly impacting the health and productivity of broiler chickens worldwide. This parasitic disease, caused by species of Eimeria, leads to considerable economic losses due to impaired growth performance, intestinal damage, and increased mortality. It also increases reliance on anticoccidial drugs. Developing nutritional solutions for broiler chicken is a promising approach to improve their overall health and resilience against diseases like coccidiosis. The objective of this study was to assess the preventive efficacy of an innovative nutritional liquid solution on zootechnical performance and coccidiosis-related lesions in broilers under field challenge. A total of 450 male Ross308 broilers were randomly allocated to three groups on a commercial farm with a documented coccidiosis history: a negative control receiving a coccidiostat-free diet (CTRL–), a positive control receiving feed containing coccidiostats (CTRL+), and a treated group (TRT) receiving commercial feed without coccidiostat plus an innovative plant-based solution. This preventive solution was provided in the water, ad libitum, from day 1 to day 41. Birds were housed in pens of 15 (10 pens per group), individually identified, and monitored for body weight and average daily gain (ADG) on days 4, 11, 21, 28, 35, and 41. Coccidiosis-related lesion scoring was performed on three birds per pen (30 birds per group) on days 21 and 28. Total oocysts count was performed at the pen level on days 21 and 28. The statistical unit varies between individual bird and pens depending on the parameter being measured. Statistical analyses were conducted at the appropriate experimental unit using ANCOVA for ADG, ANOVA for body weight, and Kruskal–Wallis tests for lesion scores and oocysts counts (significance threshold $p < 0.05$). Both TRT and CTRL+ groups consistently exhibited higher body weights than CTRL– at day 21 (991 g / 993 g vs. 957 g, $p = 0.023$), day 28 (1602 g / 1588 g vs 1503 g, $p = 0.015$), day 35 (2356 g / 2348 g vs 2187 g, $p = 0.002$) and day 41 (3051 g / 3081 g vs 2920 g; $p = 0.049$). The TRT group demonstrated a significantly higher ADG between days 4 and 11 (34 g/day vs. 32 g/day for both controls, $p = 0.05$), indicating improved early growth dynamics. On day 21, the TRT group showed a significant reduction in lesions caused by Eimeria acervulina ($p = 0.026$), indicating targeted efficacy in the early stages of infection. Furthermore, lesion prevalence also differed significantly among treatments ($p = 0.040$), with 70% of TRT birds exhibiting a 0-score compared with 50% for CTRL+ and 40% for CTRL–. No significant differences were observed on day 28, likely reflecting the onset of adaptive immune responses across groups. Oocysts excretion was similar between groups on days 21 and 28. The innovative liquid nutritional solution demonstrated preventive efficacy by reducing early coccidiosis-related lesions and supporting improved growth performance under field challenge conditions. These results support the relevance of nutrition-based strategies as complementary tools to enhance broiler resilience and mitigate the impact of coccidiosis in commercial production systems.

Effects of slow-releasing calcium supplementation on growth performance, production performance, egg quality, nutrient digestibility, and blood profile in old laying hens fed a corn–soybean meal diet

J. H. Kim[1,2], K. Lee[1,2], A. Settuba[1,2], K. Han[2], I. H. Kim[1,2]
[1] Dankook University, Department of Animal Biotechnology, 119, Dandae-ro, 31116 Cheonan, South Korea, [2] Smart Animal Bio Institute, Dankook University, 119, Dandae-ro, 31116 Cheonan, South Korea

Calcium (Ca) is one of the most critical macro-minerals in poultry nutrition, playing a fundamental role in skeletal integrity, eggshell formation, and numerous metabolic processes. In laying hens, particularly those in the late laying period, adequate calcium supply is essential because birds must continuously mobilize Ca for eggshell mineralization while maintaining bone homeostasis. This study evaluated the effects of graded supplementation of slow-releasing calcium on performance, egg quality, nutrient digestibility, blood mineral and bone turnover responses in aged laying hens. A total of 336, 54-weeks-old Hy-Line brown laying hens were randomly allocated to four treatments (7 replications, 12 hens per cage) for 12 weeks. The dietary treatments were as follows: CON, corn–soybean meal–based basal diet; TRT1, CON+ 0.25% slow-releasing calcium (SRCa) ; TRT2, CON + 0.5% SRCa; TRT3, CON + 0.75% SRCa. Data was analyzed in a complete randomized block design using the GLM procedures of SAS (SAS Institute, Cary, NC, USA). Linear and Quadratic polynomial contrasts were used to examine the 0.25- 0.75 % of SRCa supplementation. $P < 0.05$ was set as significant. Production parameters were not affected by dietary treatment. The proportion of downgraded eggs did not differ during weeks 1–6 but was significantly reduced from weeks 7–12 ($P < 0.05$) in hens fed higher levels of SRCa. Egg quality parameters were not affected during weeks 1–6 except for eggshell thickness, which was improved ($P < 0.05$) by increasing levels of SRCa during week 6; however, from weeks 7–12, eggshell strength and eggshell thickness were significantly ($P < 0.05$) increased in hens fed the 0.75% SRCa diet compared with the CON and lower inclusion levels. Apparent digestibility of ash and phosphorus was not affected by dietary treatments, whereas calcium digestibility increased ($P<0.05$) linearly in hens fed the 0.75% SRCa diet. Blood calcium concentration was increased ($P<0.05$) linearly among treatments at all post-feeding sampling times. Concentrations of parathyroid hormone, osteocalcin, and C-telopeptide were significantly reduced ($P < 0.05$) at later post-feeding times in hens fed higher levels of SRCa. In summary, dietary SRCa up to 0.75% improved eggshell quality, enhanced calcium digestibility, increased calcium circulation, and reduced bone turnover in aged laying hens without adversely affecting performance.
Keywords: Calcium, egg production, laying hen, blood mineral.

Integrating life cycle assessment into broiler feed formulation: balancing environmental gains, performance, and welfare

J. Lucas[1], A. Thomas[1], B. Ruel[1], E. Barbier[1]
[1] MG2MIX, Zone d'activité de la Basse Haye, 35220 Chateaubourg, France

Feed production is the main contributor to the environmental footprint of broiler systems, accounting for 50–97% of the impacts associated with climate change, eutrophication, acidification, land occupation and non-renewable energy use. Life Cycle Assessment (LCA) is therefore a key tool for designing feeding strategies that reduce environmental pressures at the most influential stage of production. This study evaluates the potential of LCA-driven, multi-objective broiler feed formulation to reduce environmental impacts while keeping zootechnical performance comparable to a least-cost control diet. Environmental impact values of all raw materials were incorporated into formulation software using ECOALIM V9 data, enabling optimization on six LCA indicators: climate change, non-renewable energy use, eutrophication, acidification, land occupation and phosphorus consumption. Six diets were produced: a least-cost control; four single-indicator diets targeting 15–30% reductions in either climate change or non-renewable energy; and one multi-objective formulation constraining all indicators to limit burden-shifting. Full LCAs of final feeds, including premixes, verified that predicted reductions were achieved. All targeted reductions were confirmed. Environmental improvements were mainly driven by substituting imported soybean meal with locally sourced protein ingredients (faba bean, toasted European soy, rapeseed or sunflower meal) and adjusting cereal proportions (increasing wheat, reducing maize). As expected, these changes also generated environmental trade-offs. Single-indicator formulations led to marked increases in land occupation (up to +60%), reflecting the lower yields of European protein crops compared with Brazilian soybean production. By contrast, the multi-objective formulation showed a more balanced environmental profile, reducing five of the six indicators while limiting the increase in land occupation (+27%). Importantly, it was the only diet that reduced phosphorus consumption relative to the control. Zootechnical results showed that moderate LCA constraints (R2–R4) maintained growth and feed efficiency comparable to the control. In contrast, strong constraints on a single indicator (R5: –30% energy use) decreased final weight (–3.7%) and worsened feed conversion. The multi-objective diet (R6) also showed a slight FCR deterioration, partly due to higher fine particles and fat content. This indicates that very strong constraints on a single environmental indicator may compromise growth performance, whereas multi-indicator optimization strategies maintain performance while limiting burden-shifting. Interestingly, some LCA diets (R3, R5) improved litter quality and reduced footpad dermatitis, linked to a lower dietary electrolyte balance caused by reduced soybean meal, suggesting potential welfare co-benefits. This reinforces the relevance of holistic sustainability approaches. Economically, moderate LCA diets increased cost by +3–8%, while heavily constrained diets (R5, R6) increased cost by +11–13%, partly due to poorer feed conversion. This confirms that improving environmental performance through LCA has a financial cost, which must be weighed against sustainability objectives. Overall, these findings demonstrate that integrating LCA into feed formulation is a robust and operational approach for reducing the environmental footprint of broiler diets while preserving performance relative to a conventional least-cost formulation. Future work will extend the LCA boundary to the farm-gate broiler product to quantify the system-level environmental benefits of implementing LCA-driven feed formulation strategies.

Towards sustainable pig farming in Sardinia: environmental impact and mitigation strategies

M. F. Lunesu[1], F. Correddu[1], S. Sechi[1], S. Carta[1], S. P. G. Rassu[1], A. Nudda[1], G. Pulina[1], G. Battacone[1]
[1] University of Sassari, Agraria, Viale Italia 39, 07100 Sassari, Italy

The present study aimed at evaluating the environmental impact of Sardinian light pig production by a Carbon Footprint (CFP) approach. A cradle to farm gate CFP was performed in one intensive pig farm located in Southern Sardinia (Italy). Data on on-farm activities, inputs and output were collected through farmer interview, following the UNI EN ISO 14067:2018 standard. The temporal boundary was defined from 2019 to 2022, while the functional unit (FU) was 1 kg of live weight (LW) sold. Soil C sequestration was estimated by considering the above- and below-ground biomass residues, and the organic C from slurry deposition. The replacement of conventional soy with deforestation-free soy was evaluated as a potential mitigation scenario. Farm was 85 ha in size, raised 15,721±1081 pigs, and produced 2,145±82 tons of LW from light pigs. The average light pigs slaughter weight was 117.80±0.79 kg. Light pig production resulted in a climate change (CC) impact of 3.52, 3.64, 4.04, and 3.63 kg CO2e/kg LW sold for 2019, 2020, 2021, and 2022 years, respectively. Purchased feeds were identified as the main hotspot, accounting for 73.2% of the total environmental impact across all categories. The second largest emission source was from slurry management (9.9%). When soil C sequestration was included in the model, the CC lowered on average by 2%. Replacing conventional soy with deforestation-free soy reduced CC by 16%, while emissions from purchased feeds decreased by 22%. In conclusion, the production of light pigs appears to generate fewer emissions per FU compared to the production of heavier pigs, with purchased feeds being the main environmental driver. Therefore, replacing conventional soy with deforestation-free soy could be an effective mitigation strategy to reduce the CFP of Sardinian light pig production. The authors acknowledge the University of Sassari for the financial support (Mobilità Giovani Ricercatori, annualità 2024-2025; D.R. rep. n. 4422/2025, prot. n. 148562 del 23/12/2025).

Same name, same effect? Comparative in vitro repellent activity of Cymbopogon sp. essential oils in blends against poultry red mite

C. Maltret[1], S. Cisse[1], M. E. A. Benarbia[1]
[1] Nor Feed, R&D, 3 rue Amédéo Avagadro, 49070 Beaucouzé, France

It has been described that the extensive use of synthetic molecules treatment to control parasites can lead to the emergence of resistant species. Integrated control of parasites is nowadays a necessity for a resilient layer farming industry, to preserve the efficacy of chemical treatments. Plant extracts, and more specifically essential oils, are complementary tools that are being studied for poultry red mite (Dermanyssus gallinae) (PRM) management. Previous studies demonstrated the repulsive effect of Cymbopogon nardus, but the possibility of another Cymbopogon species with a different chemical profile, like Cymbopogon flexuosus, showing the same effect was not assessed. This study examined the effects of two blends of essential oils, primarily composed of essential oils from 2 different Cymbopogon species, on PRM in vitro. A two-choice behavioural assay was performed in Petri dishes. One side contained filter paper treated with a diluted blend of essential oil (10% in ethanol), while the opposite side contained ethanol only as an internal control. The first blend (S1) is mainly composed of Cymbopogon nardus, with citronellal and eugenol as the main active compounds. The second blend (S2) is mainly composed of Cymbopogon flexuosus with neral and geranial as the main active compounds. Clean empty dishes were used as external controls, with zones randomly assigned. PRM were released in the center of the dishes, and their distribution between treated and control areas was recorded after 20 minutes. Each treatment was replicated at least 10 times. Statistical analysis was performed using a generalized linear model (GLM) with a quasibinomial distribution, and Tukey test was used as a post hoc test. A total of 1230 PRM were used for this trial, 370 for S1, 365 for S2, and 495 for the control trial. Both essential oils significantly reduced the proportion of mites in the treated area (p-value <0.05). No difference was found between the areas of control Petri dishes. In the control petri dishes, the treated area contained, on average, 56% (+/-11%) of the PRM, while in S1 and S2, the + area contained, on average, 15% (+/-10%) and 19% (+/-16%) of the PRM, respectively. No significant difference (p-value = 0.64) was found between S1 and S2. A blend of essential oils composed mainly of Cymbopogon nardus and Cymbopogon flexuosus, even with different active compounds, has a significant repellent effect on PRM in vitro. Those results may indicate that both Cymbopogon species produce secondary metabolites with similar activity regarding PRM, or that the repulsive effect is barred or supported by minor compounds or interactions found in both essential oils. This question would need to be answered by other studies.

Performance stability of local and crossbred chickens under Ascaridia galli infection

A. C. Mott[1], S. Möller[1], L. Schwarz[1], B. Sohnrey[1], C. Blaschka[1], E. Zergani[1], D. Mörlein[1], S. Weigend[2], I. Tiemann[3], J. Tetens[1]

[1] University of Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, [2] Friedrich-Loeffler-Institute (FLI),, Institute of Farm Animal Genetics, Höltystraße 10, 31535 Neustadt, Germany, [3] Hochschule Osnabrück, Faculty of Agricultural Sciences and Landscape Architecture, Emsweg 3, 49090 Osnabrück, Germany

Local chicken breeds are frequently characterized as resilient to infectious disease and environmental stressors; however, robust quantitative evidence from controlled studies remains limited. We hypothesized that they exhibit high phenotypic resilience to Ascaridia galli (A. galli) infections, defined as minimal deviation in performance traits from matched uninfected controls, and that this resilience is retained in crossbreds. Four independent experiments used three local purebred genotypes (Altsteirer, Bielefelder and Ramelsloher) and their crossbreds with White Rock (ALT x WR, BIE x WR, RAM x WR). Growth performance was evaluated in purebred and crossbred male 'brother roosters', while laying performance and egg quality were analyzed in hens. Resilience was quantified through within-experiment, within-breed comparisons to contemporaneous uninfected controls. Birds were orally inoculated with ~1,000 A. galli eggs; controls received saline. A. galli-specific antibody titers were measured at 2 weeks post-infection (wpi) and at slaughter. Infection success (>70%) was confirmed by necropsy. Individual body weight, group laying rate, and egg quality traits were recorded for up to eight weeks. Statistical analyses were performed on absolute performance data; percent deviation from contemporaneous uninfected controls was calculated post hoc to describe resilience. Each experiment was analyzed separately. Data were evaluated using general linear models including genotype, infection status and where applicable their interactions. For repeated measurements, bird was included as a random effect; group effects were considered for laying data where appropriate. Non-significant higher-order interactions were excluded from final models. Estimated marginal means were compared using Tukey-adjusted post hoc tests, and false discovery rate (FDR) correction was applied where multiple comparisons were performed. Results are presented as mean ± SE, with significance set at $p < 0.05$. Across experiments, A. galli infection produced only minor phenotypic deviations from controls. Males of both purebred and crossbred groups showed a transient increase in A. galli-specific antibody titers at 2 weeks post-infection (wpi), with variation among breeds. Weight gain differed by ≤3 % from controls ($p > 0.05$). A significant Breed × Treatment interaction was detected in crossbred layers during the early infection phase (1–3 wpi). In RAM × WR layers, infection was associated with a marked transient reduction in laying rate (-34 % relative to controls, $p < 0.001$), coinciding with decreased shell breaking strength. Production subsequently recovered, to control levels by 6 wpi. No significant effects of A. galli infection on egg quality were observed. Crossbreds exhibited numerically lower within-breed variability in percent-change responses, suggesting more consistent performance under infection. Across experiments, A. galli infection had minimal impact on performance traits. Both local purebred and crossbred chickens maintained high phenotypic stability under infection. Crossbreds exhibited lower within-breed variability, suggesting that crossbreeding with a production-oriented line may support stable performance. These findings support the use of local breeds in sustainable, free-range poultry systems where performance consistency and welfare are priorities.

Dynamic changes in plasma triiodothyronine concentrations before and after introduction of newly hatched chicks

C. Murai[1], T. Kuwayama[1]
[1] Tokyo University of Agriculture, Graduate School of Agriculture, 1737, Funako, 243-0034 Atsugi-shi, Kanagawa, Japan

Conventionally, after hens lay a clutch of eggs, they incubate the eggs and subsequently rear the chicks. This breeding cycle is referred to as broodiness. In modern laying hens, broodiness has largely been reduced or lost because of long-term selection for high egg production. However, understanding this inherent trait remains important for future breeding strategies and for maintaining genetic diversity of poultry strains. Prolactin (PRL), a hormone secreted by the anterior pituitary gland, plays a key role in maternal behavior and decreases markedly following chick introduction. The levels of other hormones also fluctuate throughout the reproductive cycle. Triiodothyronine (T3), is involved in metabolic regulation and has been reported to increase from the laying period through the incubation period and remain elevated during cohabitation with chicks. However, unlike PRL, detailed changes in T3 levels during the transitional phase associated with chick introduction remain poorly understood. In the present study, we investigated the plasma concentration of T3 before and after chick adoption. Six broody Gifu-jidori hens (a Japanese native breed) were housed individually under controlled temperature (20 ± 5°C) and photoperiod (14L:10D) conditions. On day 21 or 22 of incubation, immediately after blood sampling, five newly hatched chicks were introduced to each hen. The chicks were reared with the hen for 7 days (including the day of adoption) and then were separated. Blood samples were collected at consistent time points (17:00–18:00) on: (1) day 21 or 22 of incubation (pre-adoption), (2) days 1–3 post-adoption, (3) day 6 post-adoption (pre-separation), and (4) day 7 post-separation. Plasma T3 concentrations were measured in duplicate using a chicken-specific enzyme-linked immunosorbent assay kit. Statistical analyses were conducted using EZR, and comparisons were performed using paired t-test with a significance threshold of $P < 0.05$. Plasma T3 concentrations did not differ on days 1 and 2 post-adoption compared with pre-adoption levels; however, a significant increase was observed on day 3 post-adoption. In contrast, T3 concentrations significantly decreased 7 days after chick separation compared with pre-separation levels. Following chick adoption, a significant increase in T3 concentrations was observed in hens. This increase corresponded to the developmental stage at which chicks began to emerge from beneath the abdomens of the hen to seek food and water and to exhibit increased locomotor activity. During this stage, mother hens were required to recognize the presence of their chicks and maintain close proximity through vocalizations and movements, thereby guiding them to food and water. These findings indicate that T3 may be involved in maternal responses and behaviors in adoptive hens. Our results provide novel insights into the endocrine dynamics underlying maternal behavioral transitions in poultry.

Investigations into the farrowing process of organic sows in free farrowing systems

K. Schlegel[1], A. S. Schintag[1]
[1] Anhalt University of Apllied Sciences, Agriculture, Ecotrophology and Landscape Management, Strenzfelder Allee 26, 06406 Bernburg, Germany

A smooth and rapid farrowing process is a fundamental prerequisite for piglet health and vitality. Free farrowing systems offer distinct advantages, such as enhanced freedom of movement for the sows, but also present challenges, specifically limited opportunities for manual intervention during parturition.In 2025, 12 litters from F1 sows (German Landrace x German Large White) were monitored on an organic farm. The sows had a mean parity of 2.25. During farrowing, the duration of the birth process, inter-piglet intervals, umbilical cord condition, and the birth weights of live-born piglets were recorded and evaluated.All 12 farrowing processes proceeded spontaneously and without assistance. The average performance was 17.9 total piglets born (TB), 17.4 born alive (BA), and 10.8 piglets weaned. Gilts achieved a higher TB of 18.3 compared to 17.9 in older sows. These performance levels are categorized as highly positive. Despite the large litter sizes, the mean birth weight was 1.4 ± 0.25 kg, meeting the target weight for newborn piglets . The average farrowing duration was 245 ± 77 min, which is slightly shorter than in comparable studies. At 200 min, gilts were exactly 60 minutes faster than older sows (260 min). The mean inter-piglet interval was 14.3 ± 5.0 min. The longest intervals occurred between the 2nd and 3rd piglet (mean 29.25 min). Subsequent piglets were born at very short intervals, with only a slight increase to 17.25 min toward the end of parturition. Overall, expulsion times were brief: 69% of piglets were born within <15 min and 89% within <30 min, placing the majority of piglets within the optimal range. Only 5 out of 216 piglets had an interval exceeding 60 min, indicating a negligible incidence of dystocia. The sows utilized the freedom of the farrowing pens and moved during shorter breaks, which may have contributed to the low rate of birth interruptions. Regarding umbilical cord integrity, 91% of live-born piglets had intact cords at birth. Among the 6 stillborn piglets, only one cord was ruptured. This proportion of intact cords is remarkably high and exceeds findings in previous studies. The sows farrowed rapidly with short intervals and minimal complications. These results suggest that excellent farrowing outcomes can be achieved in free farrowing systems. Future research should investigate piglet mortality within the first three days of lactation, as this was beyond the scope of the present study.

Quality parameters of eggs from conventional and organic hens in mobile housing systems

K. Schlegel[1], J. Mühle[1]
[1] Anhalt University of Applied Sciences, Agriculture, Ecotrophology and Landscape Development, Strenzfelder Allee 26, 06406 Bernburg, Germany

Egg freshness and shell quality are critical for the marketing of shell eggs. As the lay cycle progresses, egg weight increases, while hens face physiological challenges in providing sufficient calcium for shell deposition. Similarly, egg freshness tends to decline with both increasing hen age and prolonged storage duration. The present study evaluated hens of the genotypes Lohmann Tradition and ÖTZ Coffee. From the 20th to the 53rd week of life (WHL) in 2025, five randomly selected eggs per genotype were analyzed weekly. Parameters included egg weight, shell weight, shell thickness, egg length and width, albumen and yolk height, blood spots, shell thickness (measured at the sharp end, mid-section, and blunt end), and Haugh Units (HU). Starting at 49 WHL, eggs from both genotypes were subjected to three storage trials at defined temperatures (24°C, 22°C, and 20°C) for 21 days each. For these trials, 20 eggs per genotype were used, with five eggs analyzed per week. Data were processed using SPSS, employing univariate analysis of variance (ANOVA) and correlation analyses. The average egg weight was 64.8g±9.5, with a shell weight of 8.1g±1.1. Significant genetic differences occurred for both parameters: eggs from Lohmann Tradition were heavier (67.1g±10.0) than those from ÖTZ (62.6g±8.5). Shell weights differed between Lohmann (8.4g±1.1) and ÖTZ (7.8 g ± 0.9). No significant differences were found regarding egg length (58.1 vs. 58.7 mm) or width (44.8 vs. 43.2 mm). The incidence of blood spots was significantly higher in Lohmann Tradition eggs (1.1) compared to ÖTZ (0.4). While albumen height showed no significant variation (6.9 mm vs. 6.8 mm), yolk height differed significantly (17.8 mm vs. 18.6 mm). Eggshells were thickest at the sharp end (0.316mm±0.051), followed by the mid-section (0.316mm±0.053) and the blunt end (0.310mm ±0.054), with significant differences at each site. Eggs from ÖTZ hens generally exhibited thinner shells. The mean freshness (HU) was 79.3±14.2, with no significant difference between genotypes. However, the high standard deviation indicates substantial variability. Both genotypes showed a clear trend of declining freshness with age. During the first four weeks of lay, both genotypes exhibited excellent values (Lohmann: 92.8±5.0; ÖTZ: 90.5±5.2). By the 5th month of lay, values dropped to 78.1 (Lohmann) and 72.4 (ÖTZ), reaching very low levels by the 8th (68.9, Lohmann) and 9th month (62.8, ÖTZ). Accordingly, albumen height decreased from 8.4 to 5.7 mm (Lohmann) and 7.8 to 5.0 mm (ÖTZ). The correlation between HU and albumen height was 0.91, while the correlation between HU and egg weight was -0.42. These poor baseline HU values were confirmed in storage trials. Across all three trials, freshness decreased from a mean of 60.1 (fresh) to 16.3 (at 4 weeks), regardless of temperature. In the retail sector, a minimum of 65 HU is often specified. At the start of the storage trials, 50% of the tested eggs already fell below this threshold; by the end, 100% failed to meet this requirement. The precipitous drop to such low levels in these genotypes suggests that factors other than age must be considered. In conclusions, the egg quality of conventional and organic genotypes is comparable and generally maintains a high standard. However, the significant decline in HU values early in the laying period warrants further investigation into underlying causes.

Influence of a consistent arginine supply in turkey starter diets with varying protein contents

D. Siebert[1], C. Scharch[2]
[1] CJ Europe GmbH, Unterschweinstiege 2-14, 60549 Frankfurt am Main, Germany, [2] feedtest, Löbejüner Str. 32, 06193 Wettin-Löbejün, Germany

Turkey diets are typically formulated with high crude protein (CP) and amino acid (AA) supply to support the high performance potential of modern genotypes. However, excess CP intake inevitably increases nitrogen excretion, contributing to environmental pollutions. Reducing dietary CP may not work effectively if one or more AA fall below requirements especially if requirements are not well estimated. One such AA is Arginine (Arg), which plays a role in multiple metabolic pathways, particularly as precursor of the signaling molecule nitric oxide. This study aims to demonstrate that a gradual reduction of CP in combination with a high Arg to Lys ratio will have no negative effect on growth performance of turkeys, but will lead to improvements in sustainability parameters, in particular to a reduced feed global warming potential (GWP). A total of 210 (B.U.T. Big 6) turkeys were housed in a trial facility and reared during the starter period (day 0 – 13). Pens (seven replicate pens per treatment holding 15 male birds each) were allocated to one of two treatments (T): a high standardized ileal digestible (SID) Arg to Lys ratio of 1.15 and either a commercial feed (T1: 26% CP) or a reduced CP level feed (T2: 25% CP). Diets were based on wheat, corn, soybean meal and sunflower meal, and were supplemented with crystalline Arg. Body weight (BW) was measured on days 0 and 13, feed intake (FI) determined for the period. Feed conversion ratio (FCR) and daily weight gain (DWG) were calculated accordingly. Additionally, the environmental impact of feed production was investigated through incorporating databases such as Global Feed LCA Institute (GFLI) enabling an accurate and customized environmental impact analyses. This study set the system boundary from cradle-to-feed gate following the PEF standard for feed producing animals. Performance data were statistically analysed using a one-factorial ANOVA with the fixed effect of treatment. Least square means were compared using Tukey test ($P<0.05$). Performance parameters were not affected by treatment. Final BW was numerically higher in the low CP group (T2: 396 g) than in the control (T1: 392 g), but both groups exceeded the breeder's performance objective (370 g). Feed intake (T1: 28.7 g/d, T2: 29.7 g/d), DWG (T1: 25.2 g/d, T2: 25.4 g/d) and FCR (T1: 1.14; T2: 1.17) remained with no difference between the treatment groups. The GWP of T1 was 1961 g CO2 equivalent per kg of feed while 1%-Point CP reduction (T2) reduced the GWP by about 14% to 1685 g CO2 equivalent per kg of feed. Turkeys maintain their performance despite a CP reduction in the starter phase if the AA requirements are fulfilled. The noteworthy environmental relief in the low CP group was mainly driven by the reduced soybean meal and soy oil as a result of low CP feed formulation. These results are in good agreement with a previous broiler study showing CP reduction with a consistent arginine supply (SID Arg to Lys ratio of 1.15) does not lead to a performance drop but improves sustainability parameters (Ullrich et al., 2018).

Impact of particle size and homogenisation on water populations measured by LF-NMR in poultry meat and its impact on water-to-protein ratio

M. Balasubramani[1], E. Silletti[2], C. Alvarez Garcia[3]
[1] Technological University of Dublin, Grangegorman Campus, D07 Dublin, Ireland, [2] Wageningen University, Food Safety Resercg, Akkermaalsbos 2, 6708 Wageningen, Netherlands, [3] IA2-University of Zaragoza, Animal Production and Food Quality, Miguel Servet 177, 50013 Zaragoza, Spain

Commission Regulation (EC) No 543/2008 establishes maximum water-to-protein ratio limits in poultry meat cuts; however, not univocally described guidance on sample preparation has led to inter-laboratory variability in moisture determination. We hypothesised that particle size reduction and different homogenisation procedures modify water populations distribution in poultry samples, thereby affecting measured moisture content and water-to-protein ratio (Weesepoel et al., 2019). Low-field nuclear magnetic resonance (LF-NMR) was used to provide insight on the impact of sample preparation on water populations. Two independent sample sets were used. For particle size, six retail chicken breast samples were prepared under three conditions: A) 1 cm cubes; B) ground once; and C) ground twice (both 4 mm plate). For the homogenisation trial, 96 drumsticks were distributed into four processing groups: i) two-step process without liquid nitrogen (LN), minced through a 4-mm hole; ii) three-step process using LN (in contact with the material); iii) three-step process with LN but not in contact with the sample material; and iv) three-step process with storage at −80 °C. Water populations were quantified as bound (0.1–3 ms), immobilised (20–80 ms), and free water (200–1000 ms) according to relaxation times (T_2) using an Oxford MQC benchtop NMR (McDonnell et al., 2013). Moisture (ISO1442) and protein (ISO937) contents were determined. Data were analysed by ANOVA and correlation analysis ($P<0.05$). In fresh breast samples, particle size did not affect bound water but significantly altered the distribution between free and immobilised fractions. Reduction in particle size promoted and increased immobilized water while the opposite effect was seen in free water. Moisture content decreased significantly with decreasing particle size ($P=0.005$), with twice-ground samples showing lower values than cubes. After drying the fresh breast samplers, free water was fully removed and no significant differences in immobilized and bound populations were detected. However, samples with larger particle showed less consistency and a trend to increase the observed values of immobilized water. These results suggest an interaction between particle size and water populations. It has been described (Alvarez et al., 2023) how smaller particle size favors evaporation, and we observed how it leads to less free water available. For the second trial, using drumsticks, homogenisation significantly modified the proportions of free, immobilized, and bound water in homogenates. Free and immobilised fractions were strongly and inversely correlated ($r\approx1$), reflecting the very low proportion of bound water (≈0.001%). Both fractions were highly correlated with moisture content, protein content and water protein ratio ($r = 0.67$, 0.79 and 0.79, respectively), indicating that alterations in water mobility translate into analytical differences. These results demonstrate that mechanical disruption alters water distribution patterns consistent with structural modification of the sample matrix. Particle size reduction affects evaporation dynamics leading to changes in measured moisture content. Homogenisation significantly shifts water population profiles. The data confirm that sample preparation is a critical analytical variable. Standardisation of homogenisation procedures is therefore essential to improve reproducibility and regulatory compliance in poultry water determination.

Influence of mash feed particle size selection on feed intake patterns and performance in laying hens

E. Chevaux[1], C. Villot[1], A. Sacy[1]
[1] Lallemand SAS, Rue des briquetiers, 31700 Blagnac, France

Modern birds are selected for their high feed intake to guarantee high performance. Feed is accurately formulated, but discrepancies in feed nutrient profiles can be observed between feed formulation, feed production and final feed intake. Mash feed is a challenging matrix due to particles heterogeneity, the technology of feed distribution and birds' behavior towards the selection of coarse particles first (ie. feed sorting). This study aimed at understanding the link between feed sorting and zootechnical performances. Feed intake of 52 Novogen layers of 42-week-old in individual cages was monitored during 1 week and zootechnical parameters were daily recorded during one month. A long day-length program (12–14 hours) was implemented to allow for a longer feed consumption time. Feed and feed refusals were sieved after one week, and particle size distribution was calculated. Feed sieve contained 4 consecutive sieves allowing the particles segregation in 5 categories: above 3mm, 2-3mm, 1-2mm, 0.5-1mm and below 0.5mm. Four feeding behavioral patterns were observed: 1/ for 83% of the hens, refusals contained only fines and average body gain during one month (BWGm) was +800g; 2/ for 8% of the hens, refusals were mainly composed of maize and BWG was +200g; 3/ for another 8%, refusals were dominantly soybean meal and BWGm was +900g; 4/ for 2% hens, refusals were carbonate coarse particles with an absence of BWGm. Particles size lower and higher than 2 mm were considered as fine and coarse particles, respectively. Laying performances were analyzed according to fines particles proportion in feed refusals (HIGH: more than 70%, MODERATE: between 57% and 70%, LOW: below 57%) and layer performance category (GOOD: > 5 eggs/wk, MIDDLE: 5 eggs/wk, POOR: ≤ 4 eggs/wk). Categorical data were analyzed by Khi2 test, while continuous data were analyzed by T-test to compare the 2 groups (SPSS Statistics 26.0 (IBM). Birds preferred coarse particles, eating first maize and soybean meal: the proportion of fine particles was 57% in feed and reached 70% in feed refusals. Heavier hens presented lower fines intake ($P<0.05$). As expected, POOR layers presented lower number of eggs laid per week, lower feed intake and downgraded feed conversion ratio ($P\leq0.001$). However, there was no significant difference in egg weight and hen body weight between good, middle and poor layers. In conclusion, this study demonstrates that feed sorting behavior in laying hens is highly heterogeneous and closely associated with differences in body weight gain and feed intake patterns. Indeed, nutritional imbalance due to selective feeding may affect reproductive performance before impacting body mass, highlighting the importance of feed particle size in mash feed.

Possible association between live weights and plumage or skin damages in laying hens

N. Volkmann[1], A. Riedel[1], N. Kemper[1], B. Spindler[1]
[1] University of Veterinary Medicine Hannover, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany

Feather pecking and cannibalism are multifactorial problems affecting many laying hen herds. Which hens are predisposed to get pecked and suffer from feather and skin damage is still under investigation. This retrospective study aimed to examine whether the plumage condition of light or heavy hens differed from those within the target weight provided by the breeding company. Therefore, hens' live weight as well as plumage and skin condition were recorded and analysed for potential relations. Data from five different research projects conducted on health- and welfare-related problems of laying hens housed in different housing systems were included. In sum, data were collected from 5,764 animals from 17 different flocks of untrimmed laying hens (varying genetics) during several visits over their entire laying period. Moreover, variables regarding hens' housing condition were recorded. Furthermore, at each visit, a sample of hens (50-100) was weighed and scored for plumage und skin damages (Plumage score: 6-point scale; Skin score: 4-point scale). Subsequently, depending on each hens' weight deviation from the target weights provided by the breeding company (weight group with relation to the target weights = WTW), animals were grouped as "too light" with < -10% of target weight (L-hens), as "good" showing ±10% of target weight (G-hens) or "too heavy" with > +10% of target weight (H-hens). Using a general linear mixed model, potential influencing factors on the hens' plumage and skin condition were analysed. The results showed that most hens (74.9%) were categorised as G-hens (Mean 1,823 g) while L-hens made up 13.5% (Mean 1,569.9 g) and H-hens 11.6% (Mean 2,097.4 g). Hens from all flocks showed plumage damage and increasing maximum scores over the course of the laying period. Plumage damage in one body region that was rated at least with plumage score 1 occurred in 54.1% of the monitored hens. The statistical model on plumage damage revealed statistically significant effects of the laying phase, the season, the WTW and the colour of plumage, while the housing system showed no effect. Comparisons between seasons as well as between different phases of the laying period showed significant differences and the worsening in plumage condition over the course of the year. Furthermore, the plumage scores between WTW groups revealed significant differences; the highest maximum score was recorded for L-hens. Regarding the plumage colour, hens with brown plumage showed more and severe damages than those with white feathers. The statistical model on skin damages also revealed significant effects of the season as well as the laying phase, equal to the results of comparisons observed in plumage damages. As the weight classes with relation to the target weights (WTW) demonstrated an influence on the sum of plumage damage and the G-hens showed the lowest number of animals with plumage damage over the entire laying period, the results of this retrospective study highlight the importance of good weight management in laying hen husbandry. Given the increased problems documented for the lighter animals in the L-hen group, the question remains whether low body weights or plumage damage appeared first. Thus, future studies should focus on individual hens within a flock and follow their weight development as well as plumage condition.

Helminth infections in free-range laying hen flocks in Lower Saxony: status-quo, reduction strategies and evaluation of appropriate diagnostic methods

J. Weidemann[1], M. Eilers[2], D. Jacobs[2], N. Kemper[1], J. Schulz[1], B. Spindler[1]
[1] Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), University of Veterinary Medicine Hannover, Bischofsholer Damm 15, 30173 Hannover, Germany, [2] Lower Saxony Chamber of Agriculture (Landwirtschaftskammer Niedersachsen), Mars-la-Tour-Str. 1-13, 26121 Oldenburg, Germany

With the increasing proportion of alternative housing systems, particularly free-range and organic production, gastrointestinal helminths such as Ascaridia galli and Heterakis gallinarum are gaining importance in laying hen health management. The endoparasite eggs are excreted via the feces, persist in the environment and accumulate in highly contaminated areas, especially in the vicinity of the housing facilities in free-range systems. Transmission occurs by ingestion of infective stages, directly from contaminated material or indirectly through intermediate hosts. Infections may cause clinical and subclinical impairment, including reduced nutrient absorption, decreased production performance and increased mortality. Chemical anthelmintics are commonly used to reduce helminth burdens; however, under EU-organic regulations (EU 2018/848), the application in organic production is restricted and may entail economic disadvantages. Consequently, effective alternative control strategies are increasingly required. To obtain a comprehensive overview of the current infection status of free-range laying hen flocks, to evaluate the efficacy of phytogenic and chemical anthelmintics as well as potential management strategies for reducing helminth pressure, a longitudinal field study is being conducted in 50 free-range laying hen flocks in Lower Saxony over one laying cycle. The study further aims to identify parasitological diagnostic methods that reliably reflect the flock-level helminth burden. To date, 19 conventional and 27 organic flocks were included in the study, with 32 stationary and 14 mobile housing systems. Each flock was visited three times during the production period (24, 50 and 80 weeks of age), while management and performance parameters were recorded systematically. In addition, fecal samples were collected every 10 weeks both before and after phytogenic or chemical anthelmintic treatment, to analyse and count the helminth eggs (Ascaridia galli, Heterakis gallinarum, Capillaria spp., Syngamus trachea, Trichostrongylus tenuis) per gram feces (via McMaster Method) at flock level. Additionally, deceased birds were subjected to necropsy to assess worm burdens on animal level. Preliminary results indicated that nearly 38 flocks showed no detectable helminth infections at placement (17-24 weeks of age). Infection levels increased steadily from approximately 40 weeks of age onward, with Ascaridia galli constituting the predominant species. Anthelmintic treatments applied from around 50 weeks of age reduced worm burdens, with chemical anthelmintics demonstrating the highest efficacy and, in treated flocks, reducing egg counts to nearly zero. The age-related increase highlights cumulative exposure risk in free-range systems and underscores the importance of continuous monitoring. The discrepancy between low infection levels at placement and subsequent increases indicated a key role of environmental contamination of outdoor areas in transmission dynamics. As the practical project phase is still ongoing, further analyses will clarify exposure-related transmission patterns and further evaluate the effectiveness of phytogenic anthelmintics. This project was funded as part of the EIP-Agri project Worm-free, “Status-quo of helminth burden in free-range laying hen flocks and development of a web-based application for risk assessment to improve animal health and optimize management”.

Comparative evaluation of housing systems on immunological, physiological, and productive performance in laying hens

Y. Wein[1], M. Subhi[1], S. Rubin[1], S. Mabjeesh[1], I. Yoselevitz[2], K. Shmuel[3], A. Friedman[1]
[1] The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem, Animal Sciences, POB 12, 76100 Rehovot, Israel, [2] Ministry of Agriculture, Shaham Poultry Division, POB 82, 50250 Beit Dagan, Israel, [3] Katz–Beerotayim Poultry Farm, HaNakhalim 32, 4291500 Be'erotayim, Israel

Maintaining physiological stability (homeostasis) is essential for animals' survival. Accordingly, any event that disrupts homeostasis constitutes stress, posing a threat to survival that requires substantial physiological resources to counter and restore stability. Restoration of homeostasis relies on the synergistic activity of multiple physiological systems, with the immune system playing a central and critical role. Animals raised under intensive farming conditions face numerous stressors. For several years, our laboratory has developed a minimally invasive method for measuring stress to provide reliable, quantitative markers of stress experienced by animals during rearing. This method addresses two key needs: first, improving animal welfare by identifying stressful management conditions; and second, detecting conditions that impair animal performance. To date, it has been applied to chickens (layers and broilers) and turkeys under various conditions, including stocking density, molting, feed withdrawal, transportation, and marketing. Here, using this methodology, we assessed stress status in commercial Lohmann laying hens under two housing systems (rafters' floor vs. community cages). One hundred layers were housed in four community cages, each containing 25 hens at 750 cm² per hen. The remaining 5,900 hens were kept in a free-range house with rafters' flooring at 9 hens/m², equipped with perches, nest boxes, treated drinking water lines, and feeders—all ad libitum. The experiment comprised three biological replicates. Each began with a 3-week recovery period, followed by group allocation, blood sampling after 3 weeks of treatment, and repetition of the sequence. Blood was sampled from 15 hens per treatment group per replicate. No differences were observed in physiological parameters such as hematocrit, total protein, or oxidative-active metabolites (AGEs) across groups. However, the rafters' floor group showed significant ($p<0.05$) increases in serum levels of antioxidant proteins (lysozyme and transferrin), the anti-stress hormone serotonin, anti-inflammatory cytokines (IL-10 and TGF-β), and serotonin receptor (HTR2a) gene expression in peripheral blood leukocytes (PBLs). Moreover, the rafters' floor group exhibited improvements in most productivity and egg white quality parameters, albeit at the expense of egg size and shell strength. These findings suggest that rafters' floor housing induces beneficial stress-reducing effects while having ambivalent impacts on productivity and egg quality.

Stopping detoeing in broiler breeder males is possible

R. Van Emous[1]
[1] *Wageningen Livestock Research, Animal Nutrition, De Elst 1, 6644 AA Wageningen, Netherlands*

Toe clipping of males is a standard commercial procedure to prevent excessive damage to the hens. Although toe clipping in males may thus have a positive effect on female broiler breeder welfare, the procedure can cause stress, acute chronic pain and decreased leg health in males. The Dutch government wants to implement a ban on toe clipping before 2030. Therefore two on-farm studies were conducted on 19 breeder Ross 308 and 6 Hubbard JA57 farms, each including at least one house with non-toe clipped males. At the end of the rearing phase total male mortality was recorded. During the laying phase, 60 females per house were individual assessed at 28, 35 and 45 wk of age (woa). Feather cover of the females were scored on four different body parts (back, wings, tail, thighs) and skin damage on the thighs was recorded. Skin damage was also assessed at the slaughter plant. Production performance (egg production, mortality, male%, and fertility) were recorded by the farmer per house. Additional male management (lower male%, lower male BW up to 40 woa, lower light intensity) was applied to minimize the impact of males with untreated toes. Differences between houses with treated or untreated males were evaluated using paired-samples t-tests. Four out of nineteen Ross 308 flocks had an increased mortality due to thigh damage (>1%) around 30 woa. To prevent increased mortality and decreased welfare, males in these flocks were nail clipped at approximately 30 woa. During the rearing phase, mortality (including culling) among males was on average 7.5%-point lower in untreated males compared with treated males. However, differences between flocks varied widely (0% to >21%), largely due to reduced culling for leg health problems in untreated males. Average feather cover of the Ross 308 females did not differ at 28, 35 and 45 woa, although feather cover of the thighs of the females was poorer in flocks with untreated males at 35 woa. No differences on feather cover on the thigs was observed on 28 and 45 woa. No differences on feather cover and thighs skin damage was observed in the Hubbard breeders. On average, small skin damage on the female Ross 308 thighs were higher on 28, 35, and 45 woa. This higher incidence of skin damage was also observed in Hubbard JA57 flocks at 35 and 45 woa. Across all ages, average feather cover of females was poorer in houses where only the lower percentage of males was used. Additional management measures (lower BW of males and reduced light intensity) improved feather cover. Male to female ratio was on average 1.1% lower (7.6% vs. 8.7%) than standard practice. Female mortality at 30 and 60 woa, mortality due to thigh damage, number of total eggs, number of hatching eggs, and fertility did not differ between houses with treated or untreated males. In conclusion, applying additional male management strategies enables the discontinuation in the future of toe clipping in broiler breeder males.

Breeder farm environment and age as primary drivers of offspring performance and gut microbial succession in broiler chickens

G. M. Pangga[1], A. Richmond[2], S. Bamford[2], G. Koulianos[2], N. Corcionivoschi[3], A. Psifidi[4], D. Xia[4], U. Z. Ijaz[5], O. Gundogdu[1]

[1] London School of Hygiene & Tropical Medicine, Keppel Street, WC1E 7HT London, United Kingdom, [2] Pilgrim's Europe Ltd, The Food Park 39, Seagoe Industrial Estate, Portadown, BT63 5QE Craigavon, United Kingdom, [3] Agri-Food and Biosciences Institute, 18a Newforge Ln, BT9 5PX Belfast, United Kingdom, [4] Royal Veterinary College, Hawkshead Ln, Brookmans Park, AL9 7TA Hatfield, United Kingdom, [5] University of Glasgow, University Avenue, G12 8QQ Glasgow, United Kingdom

The maternal transfer of microbiota is fundamental to host-microbe interactions, yet it remains unclear how environmental stressors in breeder chickens influence the successional trajectory of offspring microbial communities. We utilised a large-scale commercial poultry model to investigate how contrasting parental habitats across key production phases, influence the transgenerational assembly of the gut microbiome. This study compared progeny from two breeder farms with matched genetics and ages but differing management and productivity levels (Farm A: high-performing; Farm B: low-performing). Breeder caecal droppings were collected at seven timepoints (13–57 weeks; P0–P7). Progenies were sourced from breeder flocks at pre-peak (P3), peak (P4), post-peak (P5), and decline (P6) phases. In each cycle, 4,920 Ross-308 chicks were assigned to 12 pens (410 birds/pen) and reared under commercial conditions. At day 40, performance metrics, including European Poultry Efficiency Factor (EPEF) and Feed Conversion Ratio (FCR), were recorded, and faecal samples were collected. Microbiome profiling was performed using Illumina sequencing of 16S and ITS rRNA amplicons. Data were analysed using generalised linear mixed models, QIIME2, and R (phyloseq, vegan, splinectomeR). Breeder diversity was significantly influenced by both farm environment and age ($R^2 = 0.51$). Farm A exhibited high early microbial richness that declined with age and higher global bacterial Shannon diversity ($p = 0.03$), whereas Farm B maintained more even but less dynamic communities. Occupancy-abundance analysis indicated greater homogeneity and a larger fraction of core rare taxa in Farm A (55.7% above neutral model vs. 37.6% in Farm B). Conversely, Farm B showed stronger niche restriction, with 15.7% of taxa falling below neutral expectations. Phylogenetic clustering also differed significantly at 33 weeks ($P < 0.05$), with Farm A showing higher overall bacterial net relatedness and nearest taxon indices. While both breeder farm and age also significantly impacted progeny performance ($p < 0.05$ for EPEF; $p < 0.01$ for 2-kg FCR), with offspring from younger flocks and Farm B generally performing better, progeny diversity was primarily governed by parental age ($R_2 = 8\%$). However, progeny from P4 Farm A breeders exhibited higher Chao1 diversity than those from Farm B. CODA-glmnet computational modelling demonstrated that parental microbial signatures could be predicted from progeny communities with high fidelity ($R_2 = 0.90\%$). We identified a conserved transgenerational ”microbial core”: comprising Odoribacter, Clostridium methylpentosum group, Kazachstania, and an unidentified fungal taxon, that persists across the host generation gap despite environmental variation. Source tracking revealed that the breeder microbiome at P1 (20 weeks) provides the greatest contribution to the progeny gut microbiome. These results suggest that while the host environment acts as a strong selective filter for the parental microbiome, a small but robust microbial lineage maintains vertical persistence. This lineage may mediate transgenerational phenotypic effects, highlighting parental health and age as primary drivers in the early-life assembly of the host-associated microbiome.

Feeding the future: Global challenges, risks, policy solutions and the role of livestock production

N. El Benni[1]
[1] *Agroscope, Research Unit Sustainability Assessment and Agricultural Management, Reckenholzstrasse 191, 8046 Zürich, Switzerland*

Ensuring a balance between food supply and demand is essential for long-term food security. However, climate change and ecosystem degradation are placing increasing pressure on agriculture and food systems, reducing their resilience and contributing to more volatile yields. Additional pressures arise from geopolitical and global health crises, which disrupt supply chains and increase the volatility of input and output prices. While agricultural production is directly affected by these developments, it also contributes to the overshoot of planetary boundaries. This calls for measures to reduce the environmental impacts of food production. At the same time, feeding the global population with diets like those typically consumed in North America or Europe would require more agricultural land than is currently available. Therefore, shifts in consumption patterns are also needed to align food demand with supply. In order to build sustainable and resilient food systems and ensure long-term food security, a combination of short- and long-term measures is required. Whilst enhancing productivity and resource-use efficiency is widely regarded as one of the most effective short-term approaches to reducing negative environmental effects from agricultural production, achieving substantial and lasting emission reductions will also require long-term strategies that fundamentally transform agricultural production systems. To design effective and cost-efficient practices and policies that support this transformation, it is essential to consider farmers' abatement costs, and to assess and balance existing trade-offs at all levels, from farm to sector. Furthermore, a coordinated approach by all stakeholders is essential. A range of instruments, both taken by the government or private actors, can support farmers and consumers in their transition towards more sustainable food systems. Regulatory measures include restrictions on livestock stocking densities, nutrient surpluses, and greenhouse gas emissions in agricultural production, as well as restrictions on the sale or procurement of food products with high environmental impacts. Economic instruments can incentivize sustainable practices through agri-environmental payments, carbon pricing, taxes on emissions or nutrient losses, or subsidies for environmental-friendly technologies on the production side, as well as taxes on greenhouse gas-intensive foods on the consumption side. Nudges seek to influence individual behaviour without imposing restrictions on choices or substantially altering economic incentives. Examples include default enrollment in environmental programs and public recognition schemes for farmers, as well as default plant-based meal options, or menu redesigns for consumers. Information-based measures aim to improve decision-making by providing knowledge and transparency. These include agricultural extension services, advisory programs, training, and decision-support tools for producers, alongside environmental impact or carbon footprint labels for consumers. A policy toolkit that combines regulatory, economic, behavioral, and informational instruments is generally more effective than single measures in supporting the transformation towards more sustainable production and consumption patterns. Achieving sustainable and resilient food systems therefore requires coordinated transformations across production and consumption. Policy tools must be used to balance environmental, economic, and social objectives while accounting for stakeholder incentives and trade-offs. This will accelerate progress towards long-term food security and planetary health.

Navigating the perfect storm: Between Green Deal ambitions, CAP reform, and market realities

A. Matthews[1]
[1] *University of Dublin, College Green, D02 PN40 Dublin, Ireland*

Relevance. European livestock farming faces an increasingly contested operating environment. Animal scientists are asked not only to improve productivity, efficiency and animal health, but also to contribute solutions to challenges arising from climate policy, environmental regulation, animal welfare expectations and evolving consumer preferences. Understanding the economic, policy and market forces influencing the future of livestock systems is essential for researchers seeking to ensure that scientific advances remain relevant and applicable in practice. Background/Objectives. For many decades, European livestock farming operated within a relatively stable policy environment characterised by substantial public support under the Common Agricultural Policy (CAP), predictable regulatory frameworks, and expanding international trade opportunities. That environment is changing. Livestock producers are operating within a more uncertain economic and policy environment, shaped by evolving CAP priorities, changing regulatory frameworks, and increasing uncertainty in international trade policy. This talk examines the major economic and policy challenges confronting European livestock farming and explores their implications for livestock systems and animal science research. Discussion. European livestock farming is facing a perfect storm created by the interaction of policy, environmental and market pressures. First, many grazing livestock systems remain highly dependent on public support payments for their economic viability. Ongoing CAP reform raises important questions regarding the future scale, distribution and justification of this support, particularly in marginal and grassland-based production regions. Second, climate and environmental policy have become a central driver of change. Livestock methane emissions have moved to the forefront of policy debates, creating growing pressure for measurable emissions reductions. There is growing scientific evidence that some European regions have livestock densities that exceed environmental carrying capacity. In these hotspot regions, technological improvements alone may not be sufficient to achieve environmental objectives, and reductions in livestock numbers are increasingly likely to form part of future policy responses. Third, livestock sectors are increasingly exposed to global market and supply chain risks. Geopolitical tensions, supply chain disruptions and evolving trade agreements, including those involving Mercosur and Australia, create both opportunities and vulnerabilities. The pressure on European livestock producers to meet higher environmental and animal welfare standards raises questions about how competitiveness can be maintained in increasingly open markets where competing producers may not be subject to equivalent requirements. Future competition from alternative protein products may emerge in some market segments. Fourth, animal welfare is becoming an increasingly important component of both public policy and market differentiation. The future role of CAP support, regulatory standards and market-based incentives in promoting improved welfare outcomes remains an important area of debate. Conclusion. The future of European livestock farming will be shaped not only by advances in animal science but also by broader economic, political and societal developments. The social licence for animal agriculture will be retained not only by demonstrating its contribution to food security, rural livelihoods, environmental stewardship and animal welfare, but also by how it responds to societal concerns. How livestock systems adapt to these challenges, and how animal science contributes to that adaptation, will play a critical role in determining the future place of livestock farming within European agriculture and society.

Unpacking the promises of technology in farming: The economic challenge

H. Hogeveen[1], M. Van Der Voort[1]
[1] Wageningen University and Research, Business Economics group, Hollandseweg 1, 6706 KN Wageningen, Netherlands

In the past decades, many authors have described the promises of the use of technology, especially precision livestock farming (PLF). However, although not many scientific studies are available, it seems that adoption of PLF technology lags behind. This despite a large number of larger or smaller research projects and many scientific publications. One of the elements that deserves our interest is the aspect of value of technology. Although technologies ensure various dimensions of more precise information, it is important to assess the value of the added precision of information. The value of information from PLF technology can only be unpacked if decisions that are taken, based upon the technology are (economically) better than decisions taken without this technology. Although PLF technology is aimed at farm animals, the potential use of information can be upstream or downstream from animal production. For instance in monitoring animal welfare, phenotyping potential breeding traits or monitoring environmental aspects such as NH3 emissions. All the value propositions of PLF technology are based upon the assumption that farmers will invest in this technology. However, it seems that the adoption of PLF technology has stagnated in recent years. A recent literature review aimed at PLF technology for improved health, showed that in 132 peer reviewed articles, published in the last 10 years, only 3 evaluated the use of the technology in decision making. All others were mainly aimed at algorithm development. These results more or less confirm the disappointing development of adoption of PLF. Research is still focused on detection algorithms, while in the evolution of research one would expect more work on the integration and automation levels. One of the approaches to unpack the potential of PLF technology is to change the perspective of research and application. Most research up to date is aimed at the development of PLF systems to support more or less traditional management. For example, almost all research aimed at improved mastitis management using PLF technology, is aimed at detecting clinical mastitis. However, reasoning from the potential of PLF technology in mastitis management, a number of other managerial areas could be determined. Which means that the sensors can be used in much more than one way. A second example that we studied lies in the detection of suboptimal mobility. Research typically is aimed at detecting lame cows, for curative trimming. By simulation modelling we showed that with changes in hoof care management enables a cost-effective use of PLF technology that also resulted in improved dairy cow welfare. Similarly we are working on the potential of sensors in poultry farming, looking at the potential value of PLF technology to improve management of coccidiosis. A final example of the need for creating value on the use of technology is in the development of sensors to monitor environmentally harmful gasses such as ammonia (NH3) in dairy barns. Such systems may be immensely important to reduce the environmental footprint of production. However, without a decent value proposition, they will not be used, leaving their potential unpacked. In conclusion (PLF) technology provides a lot of promises to improve the quality of animal production. To unpack these, future research must integrate technology with clear management and show the (economic) value of the use of these technologies. Simulation modelling is a useful tool to embed (economic) impact evaluation alongside sensitivity and specificity metrics and determine the tradeoffs between them. Addressing these technical, integration, and economic challenges is essential before technologies can contribute to value-driven animal management on commercial farms.

Beyond pure productivity: The strategic role of genetics, resilience, and health for business continuity

W. Rauw[1]
[1] *INIA-CSIC, Dept Animal Breeding, Ctra de la Coruña km 7.5, 28040 Madrid, Spain*

Before the 1940s, animal breeding primarily entailed pure breeding, and breeding objectives for livestock were predominantly visual, toward an "ideal type" for the breed. Subsequently, breeding evolved from objectives of appearance to objectives involving performance. For example, the primary aim in broiler and pig production is rapid growth, superior feed efficiency, and high lean tissue growth rate. When it became recognized that animals selected for high production efficiency are more at risk for behavioral, physiological and immunological problems, the concept of sustainability has come to play a prominent role in agricultural production, resulting in broader defined breeding goals that include not only production traits but also functional traits, such as longevity and health. Livestock animals are required to perform in a wide variety of environmental conditions regarding climate and disease pressure, therefore, animals need to be selected that have the ability to combine a high production potential with resilience to stressors, allowing for unproblematic expression of a high production potential in a wide variety of environmental conditions. However, there is a lack of clearly defined indicator traits of resilience, which yet have to be included in standard breeding programs. Novel phenotypes of resilience can be based, for example, on fluctuations in production traits over time. Selection strategies for sustainable production systems can support high input–high output systems (sustainable intensification), where animals are selected for maximized production efficiency in environments controlled by precision livestock farming techniques. Alternatively, breeding strategies can support reduced input–reduced output systems based on selecting animals that are more robust to climate change and are better adapted to transform low quality feed (local feeds, feedstuff co-products, food waste) into meat. The latter scenario may result in reduced predicted yields, reduced production efficiency and possibly increased costs to the consumer. In particular, autochthonous breeds produced in and adapted to the local environments may harbor the genes necessary to adapt to suboptimal environmental conditions; marketing initiatives like the Spanish "100% Autochthonous Breed" label may help promote and conserve these breeds through market differentiation of their products. Genetic selection can also be applied to optimize other links in circular agricultural systems. For example, besides genetic improvement of livestock breeds (genotypes better adapted to the impacts of climate change, performing well on locally sourced, feed ingredients of variable quality), selection may be applied to local feed crops (enhancement of yield, protein content, stress tolerance, and attractiveness to pollinators, and reduction of anti-nutritional factors) and crop pollinators (improvement of pollination efficiency, foraging behaviors, or the capacity to vector biocontrol agents). In addition, animal breeding practices have become part of the debate that deals with issues of animal welfare and animal production ethics, where animal breeding goals may be broadened further to include emotional and societal values, such as animal well-being. It is the aim of the present perspective to present an overview of sustainable breeding goals that balance production potential with resilience and environmental sensitivity, increasing or restoring the animals' ability to interact successfully with the environment and improve welfare and productivity. For the successful implementation of sustainable production systems, cooperation is needed regarding all multidisciplinary actors involved.

The other side of a Curriculum Vitae: A case study in animal science

G. Bee[1]
[1] *Agroscope, Swine Research Group, Route de la Tioleyre 4, 1725 Posieux, Switzerland*

A curriculum vitae records what a scientific career produces. It does not record how it actually works. Research careers in animal science are rarely the product of strategic planning. More often they emerge from a sequence of methodological investments, external constraints, and network effects that are only retrospectively legible as a coherent trajectory. This lecture uses one 35-year publication record in pig nutrition and meat science as primary evidence, chosen not because the career is exceptional, but because it is the only one for which all details, including the unflattering ones, are fully accessible. The record, spanning lipid metabolism, conjugated linoleic acids, pork quality and proteolysis, intrauterine growth restriction and foetal programming, boar taint, tannins as bioactive feed additives, protein and nitrogen efficiency, and former food products, is analysed not as a list of achievements but as a dynamic system driven by four identifiable forces: exhaustion of ideas, loss of financing, limits of personal knowledge, and dissolution of collaborating networks. A fifth force, pure curiosity meeting a prepared toolbox at a conference session, explains at least one major redirection that none of the other four can account for. A central argument is that methodological investments, once made, produce scientific returns over timescales that greatly exceed any single project or funding cycle. The corollary is that the value of a formative research period cannot be assessed from its immediate output alone. A second argument concerns what the lecture calls side effects: the committee memberships, editorial appointments, policy engagements, COST actions, and European research projects that accumulate alongside a publication record and that frequently prove more consequential than the publications themselves. These are not outputs of a career plan. They are consequences of sustained presence in a scientific community, built at conferences, in working groups, and over too many drinks considerably later than was advisable. The other side of a curriculum vitae is where a scientific career actually happens. So much for the past. What about the future? Animal science in 2040 will still be driven by the same fundamental curiosity, understanding the relationship between what an animal eats and what it becomes. But the questions that curiosity generates will be shaped by forces that do not yet have names. That is not a problem. Artificial intelligence, precision phenotyping, and multi-omics are not a revolution in what we want to know, they are a new toolbox, arriving faster than any previous one. These tools will reward the scientist who knows what question to bring to them. They will be less useful to the scientist who mistakes the tool for the question. Curiosity built this career. It will build the next ones too.

Economics of Genomic Improvement: How to Enhance Productivity While Reducing Environmental Impact

G. Cartick[1], L. Fontanesi[1]
[1] FABRE TP, 61 Rue de Trèves, 1040 Brussels, Belgium

Genetic improvement has long been a key driver of productivity in livestock systems. Today, it is increasingly recognised as one of the most impactful and cost-effective approaches to simultaneously improve productivity and reduce the environmental footprint of animal production. However, despite strong evidence of its benefits, the economic value of animal breeding is still not fully recognised across the value chain and is sometimes underestimated in sustainability debates. Advances in breeding technologies—supported by improved data availability, enhanced trait recording, and more precise selection methods—enable breeders to target traits that improve resource efficiency, robustness, health, longevity, and emissions intensity. Yet adoption remains unbalanced across species, production systems, and regions, reflecting differences in data infrastructure, investment capacity, market incentives, and policy support. There is therefore a clear need to reaffirm the role of animal breeding within the three pillars of sustainability: economic viability, environmental performance, and societal benefit. This FABRE TP Challenge session at EAAP 2026 will explore how investments in modern breeding approaches can deliver measurable gains for productivity while reducing environmental impact, and which economic and policy frameworks are needed to ensure that these benefits effectively reach breeding programs, farmers, and society. The session will examine how improved recording systems and phenotyping technologies provide the foundation for selecting animals that produce more with fewer inputs, lowering production costs and environmental burdens per unit of output. Speakers from academia, breeding organisations, industry, and agricultural economics—covering multiple species and production systems—will address key questions such as: What is the economic value of breeding, and how can this value be demonstrated across species?How do improved phenotyping systems, data infrastructures, and selection tools influence costs, returns, and risk along the value chain?How can productivity gains and environmental improvements be robustly measured, compared, and monetarized?What incentives, collaborations, and governance structures are needed to ensure that farmers and other actors benefit from upstream genetic progress?In line with FABRE TP's mission, the session emphasizes responsible, science-based breeding, strong cooperation between research and industry, and policy frameworks that recognise the contribution of genetic improvement to EU climate, food security, and sustainability objectives. A series of short expert presentations will be followed by an extended roundtable discussion, actively engaging the audience in identifying practical challenges, cross-sectoral solutions, and pathways for wider uptake. In conclusion, the 2026 FABRE TP Challenge aims to provide participants with a clear understanding of how economically viable breeding innovation can simultaneously enhance productivity and environmental performance, and how coordinated action across research, industry, policy, and practice can unlock its full potential across Europe's diverse livestock systems.

What kind of breeding for a sustainable livestock production worldwide? global priorities, constraints, and pathways forward

G. Leroy[1], P. Ajayi[1], A. Uwizeye[1], N. Rakotovao[1], P. Boettcher[1]
[1] Food and Agriculture Organization of the United Nations, Viale delle Terme di Caracalla, 00153 Rome, Italy

As livestock production systems worldwide face mounting socio-economic and environmental pressures, breeding strategies must increasingly navigate complex trade-offs between productivity, resilience, and environmental impact. Advances in genomics and genetic evaluation are creating new opportunities to select animals with lower methane emissions without compromising productivity. Evidence shows that methane-related traits are heritable and can be integrated into multi-trait selection indices. Drawing on preliminary findings from the Third Report on the State of the World's Animal Genetic Resources, this contribution explores emerging global priorities, recent improvements, persistent gaps, and potential solutions for more sustainable breeding approaches. The diversity of production environments and stakeholder needs underscores that no single strategy can fit all contexts. Instead, breeding decisions must be framed holistically, integrating genetic, economic, and ecological dimensions, while also recognising the practical limitations imposed by field conditions, infrastructure, and capacity constraints that shape what is feasible in breeding programmes on the ground. Investment in research, phenotyping and breeding programmes will therefore be essential to support climate-smart livestock development and align genetic progress with mitigation goals.

Challenges in breeding for reduced environmental impact and other eco-system services

P. Berg[1]
[1] *Norwegian University of Life Sciences, Animal and Aquacultural Sciences, P.O.Box 5003, 1432 Aas, Norway*

Breeding objectives have shifted from initially focusing on productivity to profitability by including more traits related to efficiency, health, and fertility. Ecosystem services, such as reduced environmental impact, have largely not been valued and thus not been thoroughly considered in defining breeding objectives. The possibilities and challenges of including environmental impact in defining breeding objectives are highlighted, with a focus on the value chain of improved genetics vs the value chain for animal products.

Unlocking genetic progress: importance of data-driven selection to enhance productivity, economy and environmental impact

L. P. Sørensen[1]
[1] *Viking Genetics, Ebeltoftvej 16, DK-8960 Randers SØ, Denmark*

Genetic improvement in dairy cattle creates cumulative and long-term value, but its economic and environmental benefits are not always measured consistently across the value chain. This presentation explores how breeding progress translates into farm-level profitability, improved production efficiency, and reduced environmental intensity. Genetic gain can be expressed through higher milk and solids output, lower feed and health costs, and greater resilience, with impacts measurable in €/cow/year and over longer-term sector performance. The presentation also highlights the importance of phenotyping, genomic selection, and data infrastructure in increasing selection accuracy and accelerating genetic progress. Better phenotypes for traits such as health, resilience, and methane proxies, combined with interoperable data systems and robust governance, improve both returns and risk management. Environmental outcomes can be assessed through emissions intensity and life cycle assessment approaches, while monetization frameworks support valuation of productivity and carbon-related gains. Finally, the presentation discusses incentives, collaboration, and governance mechanisms needed to ensure fair benefit-sharing among farmers, breeding organizations, processors, and society. Transparent data rights, co-funding models, and outcome-based approaches are essential to capture the full value of breeding innovation.

Balancing profit, greenhouse gas emissions and resilience in dairy cattle breeding using integrated modelling approaches

R. Shi[1]
[1] Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France

Genetic improvement offers a cumulative opportunity to improve both productivity and environmental sustainability of livestock systems. While substantial research has focused on phenotyping individual greenhouse gas (GHG) emissions to enable direct selection for lower-emitting animals, environmental impacts also depend on herd dynamics, production efficiency, and resource use across the production chain. System-level indicators such as GHG emission intensity (EI) therefore provide a complementary perspective for linking genetic improvement with environmental outcomes. Moreover, EI indicators can be used to derive emission intensity values (IVs) of traits, analogous to economic values in breeding indices, enabling environmental objectives to be explicitly considered in breeding programmes. Meanwhile, increasing climatic variability highlights the importance of selecting animals that are resilient to environmental perturbations. However, the combined implications of EI indicators and resilience-oriented breeding objectives remain insufficiently investigated. In the recent studies, an integrated modelling framework linking environmental assessment and genetic simulation was developed. First, a herd-level bio-economic model coupled with life-cycle assessment (LCA) was used to estimate EI of dairy production and to derive IVs for key traits by quantifying the marginal impact of genetic changes on emissions along the production chain. These IVs were used to explore breeding indices balancing farm profitability and EI. Building on this framework, long-term breeding scenarios under climate change were simulated for alternative objectives prioritising either milk production or resilience traits. Phenotypes were simulated using mechanistic models of dairy cow physiology and were translated into herd dynamics, allowing the economic and environmental consequences of breeding objectives to be evaluated. The analysis showed substantial variation in the contribution of traits to both farm profitability and EI. Derived IVs revealed potential trade-offs between economic and environmental outcomes when constructing breeding indices. Simulated resilience-oriented breeding resulted in cows producing less milk per day but with earlier conception, lower dry matter intake, extended productive lifespans, and improved ability to cope with short-term perturbations. These changes improved the cow's lifetime profitability and reduced EI, despite a reduction in annual profit per cow compared with the production-oriented breeding objective. Collectively, these findings illustrate how IVs can complement traditional economic values to integrate environmental considerations into breeding indices while highlighting the potential long-term benefits of selecting for resilience in dairy cattle populations. Linking breeding simulations, mechanistic modelling, and LCA provides a comprehensive framework to evaluate sustainable breeding objectives. Such approaches could contribute to the design of breeding objectives that better balance profitability, resilience, and GHG mitigation in dairy production systems.

Investments in modern genomics and digital phenotyping to improve the economics of livestock production systems

D. Bickhart[1], N. Duijvesteijn[1]
[1] Hendrix Genetics, Spoorstraat 69, 5831 CK Boxmeer, Netherlands

The global population is expected to exceed 9 billion by 2050, requiring substantial improvements in the efficiency of food production systems to meet rising demand. Livestock production will play a critical role in supplying high-quality protein, making continued refinement of breeding and production systems essential for both nutritional security and economic viability. Selective animal breeding has already delivered major gains in productivity and efficiency, with direct economic benefits for farmers. For example, egg production in laying hens has increased by more than 27% since the 1960s through genetic improvement, enabling higher output per animal, lower resource use per unit of product, and more predictable performance. These improvements translate into reduced production costs, improved margins, and greater resilience to market volatility at farm level. Conventional breeding approaches, however, rely heavily on phenotypic data that can be costly to collect or may raise animal welfare concerns. Investment in digital phenotyping technologies—such as computerized tomography image analysis and camera-based locomotion modeling—allows performance data to be collected with minimal animal disturbance and reduced labor input. This accelerates genetic progress while lowering operational burdens for farmers, supporting economically sustainable production systems. At the same time, not all production contexts are suited to intensive systems. Breeding strategies must also support cage-free systems and smallholder farming, where livelihoods and local economies depend on robust, adaptable animals. Innovations such as DNA-based tracking and egg printing technologies enable performance monitoring in cage-free laying hen systems, supporting regulatory compliance without compromising farm income. In parallel, programs focused on providing locally adapted poultry lines to rural farmers in Africa demonstrate how breeding can strengthen household incomes, support profitable value chains, and improve access to animal protein. Addressing the global food challenge will require steady, incremental improvements in breeding and technology that deliver higher efficiency, improved animal welfare, and tangible economic benefits for farmers across diverse production systems.

European integration of phenotyping, genomic and data research facilities to foster sustainable animal production and aquaculture

E. Labussiere[1], R. Baumont[2]
[1] INRAE, PEGASE, 16 Le Clos, 35590 Saint-Gilles, France, [2] INRAE, UMR Herbivores, Theix, 63122 Saint-Genès-Champanelle, France

European research in farm animals is mostly organized at a country and even at an institute level whereas the challenges faced by farm animal research cross borders. Additionally, the increasing needs for detailed phenotyping of animals in various environments question the adequacy between farm animal research capabilities and the questions initiated by the agroecological transition and the increasing society concerns about animal welfare and ethics in science. The desire to describe the components of overall characteristics more precisely requires measurements, samples and data that should be easily obtained from a large number of individuals, using procedures that are as non-invasive as possible, while achieving a high degree of accuracy. The needs for phenotyping tools dedicated to various and detailed traits to support the breeding of multi-purpose animals adapted to challenging and changing environments (associated with climate change, mitigation strategies, availabilities of feed resources) have not always been addressed because of a non-common research field and the lack of efficient connections between phenome and genome sciences. During the last decade, several attempts to align the needs for breeding and phenotyping tools based on a deep understanding of the relationships between biological traits have emerged, resulting in promising examples of traits especially developed to describe specific characteristics of animals. A first example is based on the partitioning of feed efficiency in growing pigs between what is due to the digestive utilization of diets and what is due to the metabolic utilization of nutrients. Based on the observation of a genetic contribution to the variability with which a pig digests a diet, a method based on a near infrared spectroscopy of a fecal sample has been developed to be able to breed pigs especially able to digest efficiently diets with a low nutritional value. A second example is the consideration of strategies to reduce methane emissions from dairy cattle in a breeding index together with economically important traits. The individual methane emissions of each cow have been evaluated thanks a method based on milk mid-infrared spectroscopy to document their genetic determinism. These two examples were supported by samples, measurements and data analyses relatively small in size in the way they only consider national or even regional populations of animals. These approaches can be further extended at the European level, also taking advantage of the differences in climate, species and breeds with their specific breeding strategies. Major advances in common trait definition and phenotyping procedures have pave the way to the development of a common infrastructure to integrate phenotyping, genomic and data research facilities. Such an infrastructure should be thought to efficiently develop in vivo and in vitro phenotyping, genomic tools, biobanking and data sharing and workflows so that it will be able to address complex research questions on farm animals and to translate results into impacts for animal breeding and farming.

Image-derived latent features as digital biomarkers for large-scale genetic evaluation

M. Billah[1], M. Bermann[1], C. Y. Chen[1,2], E. Psota[2], B. Valente[2], J. Holl[2], I. Misztal[1], D. Lourenco[1]
[1] University of Georgia, Department of Animal and Dairy Science, 425 River Rd, 30602 Athens, United States,
[2] Genus PIC, 100 Bluegrass Commons Blvd, 37075 Hendersonville, United States

Integrating high throughput phenotypic features into genetic evaluations is essential for improving prediction accuracy and capturing complex biological variation. Although image-derived features are widely used as proxies for ground-truth measurements, their potential as digital biomarkers in breeding programs remains largely unexplored. In this study, we leverage two deep learning architectures, Vision Transformer (ViT) and β-Variational Autoencoder (β-VAE), to extract interpretable latent features from porcine images and assess their genetic potential as digital biomarkers. The ViT models were pre-trained on the ImageNet dataset to generate high-dimensional image embeddings, whereas the β-VAE models were trained on our custom dataset using an encoder-decoder architecture that learns compact latent representations. Our approach processes segmented images to generate N-dimensional latent variables, with the number of features determined by the model architecture, ranging from 768 to 1024 for the ViT models and 128 for the β-VAE models. To evaluate how image-derived latent representations capture systematic effects, we computed attribute-specific correlation matrices for several key factors, including contemporary group, birth year and month, birth farm, gender, and litter. We then estimated the genetic parameters of each latent feature using linear mixed models to verify that image-derived features can capture a heritable genetic signal. Finally, we developed three methods to construct digital similarity matrices from these features, including correlation-based, cosine similarity, and RBF kernel formulations, and evaluated their consistency with traditional pedigree and genomic relationship matrices. The proposed approaches were evaluated using a large-scale dataset comprising 15.9M pedigree records, 561.7K two-dimensional side view body images from 24K individuals, and 17.7K genotyped animals. Our results demonstrated that image-derived embeddings capture high-resolution signals for environmental, temporal, and phenotypic information. Specifically, ViT-derived embeddings exhibited more distinct correlation structures for systematic effects than β-VAEs, even when using a pre-trained model. These latent variables exhibited moderate and heterogeneous heritability, with estimates ranging from 0.06 to 0.49, confirming their capacity to represent a significant genetic signal. Finally, similarity matrices constructed from ViT embeddings were more correlated with pedigree and genomic relationship matrices than β-VAE based approaches, with correlations ranging from 0.27 to 0.31. Overall, these results demonstrate that image-based latent features can function as digital biomarkers for genetic evaluations, offering a novel covariance component to augment traditional pedigree or genomic relationship matrices and enhance the partition of phenotypic variance.

Extending Single-Step Genomic Evaluations to Phenomics and Intermediate Omics: A Conceptual and Methodological Perspective

N. Gengler[1], A. Genin[1], A. Markey[1]
[1] University of Liège, Gembloux Agro-Bio Tech, TERRA Teaching and Research Center, Passage des Déportés, 2, B-5030 Gembloux, Belgium

Phenomic selection and the integration of intermediate omics information are emerging strategies to enhance the prediction of complex traits in animal breeding. Both approaches exploit high-dimensional biological data—such as infrared spectra, metabolomic or volatilomic profiles, transcriptomic measurements, and imaging-derived features—to capture biological variation not fully explained by traditional genotyping. These data layers contain functional and environmental information that often precedes or modulates genetic expression, providing complementary insights into the biological mechanisms underlying quantitative traits and opening new avenues for precision breeding. Despite their increasing empirical use, the conceptual and methodological link between such high-throughput data sources and conventional genomic evaluation frameworks remains underdeveloped. This work proposes a unified perspective that positions phenomic and omics data as relationship layers, analogous to genomic and pedigree-based relationships. This interpretation enables the joint estimation of random effects and the evaluation of individuals across multiple information sources within a single modeling framework. In conventional genomic evaluation, genotyped individuals contribute a relationship matrix reflecting additive genetic similarity, which can be extended in a single-step framework to include non-genotyped animals through pedigree information. By analogy, when phenomic or omics features are used to construct similarity matrices, the resulting kernels are often implicitly treated as if they arise from perfectly heritable signals. Recognizing, quantifying, and revisiting this assumption is essential for properly interpreting and extending single-step evaluations when integrating high-throughput biological data. Each data source – pedigree, genomic, phenomic, or -omic – defines its own relationship structure, which can be combined within multi-kernel mixed models or incorporated into neural-network architectures where intermediate features act as latent layers. Such multi-layer representations allow information to propagate across biological levels and between individuals, capturing both direct genetic effects and indirect effects mediated by functional or physiological traits. By formalizing phenomic and omics kernels as additional relationship layers, this conceptual extension provides a rigorous basis for combining heterogeneous data types, improving predictive accuracy, and enabling the inclusion of individuals with incomplete or missing measurements. The proposed concepts will be exemplified using Raman spectroscopical and volatilomic profile data associated with boar taint, illustrating how, potentially, high-throughput phenomic information can be operationalized within a single-step evaluation framework. This integration clarifies assumptions about heritability, information transfer, and biological relevance, supporting the development of flexible, data-rich, and biologically grounded multi-layer prediction systems for future livestock breeding programs.

Metabolic signatures after genetic selection of litter size homogeneity and resilience in a maternal rabbit line

C. Chandrababu Shailaja[1], M. J. Argente[2], M. L. García-Pardo[2], P. Hernández[1], M. Martínez-Álvaro[1]
[1] Institute of Animal Science and Technology, Universitat Politècnica de València, Camí de Vera, s/n, Algirós, 46022 Valencia, Spain, [2] Department of Agri-Food Technology, Institute for Agri-Food and Agro-Environmental Research and Innovation (CIAGRO-UMH), Miguel Hernández University of Elche, 03202 Orihuela, Spain

Selection for resilience in animal farming is an attractive strategy to ensure productivity under environmental challenges while promoting long-term welfare. Resilience is often defined as the ability to maintain production levels under environmental perturbations throughout the productive life, which is costly and difficult to measure. With the revolution in omics data, many studies have identified phenotypic biomarkers of resilience; however, their genetic basis and potential use for breeding are usually unexplored due to a lack of data or proper experimental design. A divergent selection experiment in rabbits at the University Miguel Hernández (Orihuela, Spain) for intra-dam phenotypic variance of litter size after correcting for year–season and lactation status produced lines with homogeneous and heterogeneous litter sizes. After 17 generations, the lines differed by 1.58 kits² (0.49 standard deviations), attributable to genetics. A preliminary study in generation 13 observed different inflammatory and immune responses between the lines targeting a few specific biomarkers (blood leukocyte counts, TNF-alpha, and C-reactive protein), although the full picture of the biological mechanisms underlying resilience remained poorly understood. This study compared the comprehensive plasma metabolic profiles of these two lines in two different generations (13 and 17) to identify plasma metabolites responding to selection for resilience. Candidate biomarkers were identified in generation 17 and subsequently validated in generation 13 to reduce false-negative detection rates associated with high-dimensional data ($p >> n$). Blood samples were collected 24 hours after first kindling from 40 randomly selected does per generation (13 and 17). Untargeted plasma metabolomics using a semipolar approach identified 1,397 metabolites in generation 13 and 1,170 in generation 17. Metabolite abundances in generation 17 were chi-squared normalised prior to a preliminary screening that retained 180 metabolites with relative abundance differential mean ($n = 69$) or variance ($n = 131$). Differential means were estimated with Bayesian linear models, while differential variance was assessed using Fisher's F-test. Lines were classified through logistic regression, partial least squares discriminant analysis (PLS-DA), and random forest following different transformations of the 180 metabolites: chi-squared normalization, pairwise log-ratio (LR), centered log-ratio, and additive log-ratio. Model performance was evaluated across 100 iterations of repeated 70:30 train–test splits, incorporating algorithm-specific feature selection. The highest classification accuracy was achieved by PLS-DA using LR. An additional PLS regression analysis identified informative metabolites related to resilience by overlapping pairwise LRs from PLS and PLS-DA ($n = 167$). This subset was then validated in generation 13 with common metabolites ($n = 16$). Consistent cross-generational differences were observed in LRs primarily composed of 3-hydroxy-4,5-dimethyl-3(5H)-furanone, but also creatine, 3-methylglutarylcarnitine, and N-(3-acetamidopropyl)pyrrolidin-2-one, linked to energy metabolism, immune regulation, and stress adaptation. The next step is to further investigate the biological link between these metabolites and resilience, and their potential in resilience-focused breeding.

Resolution matters: 16S rRNA and Shotgun Metagenomics in estimating microbiome-mediated genetic variance in Iberian pigs

L. Azouggagh[1], C. Casto-Rebollo[2], L. Varona[3], J. Casellas[4], S. Negro[5], N. Ibañez-Escriche[1]
[1] Universitat Politècnica de Valencia, , 46022 Valencia, Spain, [2] Lohmann Breeders GmbH, , 27427 Cuxhaven, Germany, [3] Universidad de Zaragoza, , 50013 Zaragoza, Spain, [4] Universitat Autònoma de Barcelona, , 08193 Barcelona, Spain, [5] INGA FOOD S.A, , 06200 Almendralejo, Spain

Recent developments in metagenomic technologies have facilitated the incorporation of microbial information into animal breeding strategies, providing new insights into the role of host-microbiome interactions in shaping phenotypic diversity. In this context, the present study evaluated and compared two sequencing methodologies, 16S rRNA gene sequencing and shotgun metagenome sequencing (WGS), to assess their capacity to characterize microbial and genomic contributions to meat quality and carcass traits in Iberian pigs. A total of 162 pigs were raised under standardized conditions at the Iberian Testing Center (Inga Food, Spain). Fecal samples collected before slaughter (≈365 days) were analyzed using nf-core/ampliseq (16S) and SqueezeMeta (WGS). After quality control, WGS retained 275 genera, 212 species, and 4527 KEGG Orthologs (KOs), whereas 16S retained 154 genera, 44 species, and 1775 KOs. Animals were genotyped with the Illumina GGP PorcineHD BeadChip (35,285 SNPs post-QC). Phenotypes included fatty acid (FA) composition of longissimus thoracis and carcass and primal-cut yields (ham, loin, shoulder). A three-step Bayesian framework (BGLR, R) was applied. First, microbiability was estimated using a mixed model with additive genetic and microbial random effects. Second, BayesC regression estimated microbe-specific effects including additive genetic effects and microbial abundances. Third, each microbe was modeled as a quantitative trait to estimate its additive genetic variance, allowing estimation of the fraction of trait genetic variance mediated through each microbe, and ranking taxa according to their contribution. Both approaches detected relevant microbial contributions. At the genus level, microbiability estimates were similar for FA traits (16S: 0.20–0.23; WGS: 0.22–0.24) and carcass traits (16S: 0.14–0.32; WGS: 0.14–0.20). At the species level, WGS yielded markedly higher estimates than 16S for FA traits (0.19–0.27 vs. 0.09–0.11) and carcass traits (0.14–0.20 vs. 0.07–0.11), except for ham yield (16S: 0.21; WGS: 0.19). At the functional level, estimates were comparable (16S: 0.16–0.33; WGS: 0.15–0.32), with 16S slightly higher for most traits. Microbe-specific regression coefficients showed strong heterogeneity, with few taxa explaining large proportions of microbiome-mediated genetic variance. At the genus level, Prevotella, Lactobacillus, and Streptococcus explained 37–93% depending on the trait. At the species level, Escherichia coli, Lactobacillus amylovorus, and Streptococcus gallolyticus accounted for 22–93% depending on phenotype. Overall, similar estimates at genus and functional levels indicate comparable performance of both methods at these resolutions. In contrast, substantially higher species-level estimates from WGS indicate stronger support for species-associated variance components, whereas lower 16S estimates reflect limited species resolution. Thus, WGS is required to detect species-level effects, while 16S is adequate for genus- and function-level analyses.

Does the inclusion of microbiome data enhance genetic evaluations? Evidence from GBLUP and GO-BLUP comparisons in beef cattle

S. N. Saez-Torillo[1], T. Q. Nguyen[2], J. Lima[2], M. A. Cleveland[3], R. Roehe[2], M. Martínez-Álvaro[1]
[1] Institute of Animal Science and Technology, Universitat Politècnica de València, Camí de Vera, s/n, Algirós, 46022 València, Spain, [2] Scotland's Rural College, Kings Buildings, West Mains Road, EH9 3JG Edinburgh, United Kingdom, [3] Genus plc, 1525 River Road, 53532 DeForest, United States

Genetic improvement in cattle relies on accurate prediction of estimated breeding values (EBVs) for traits of economic relevance, particularly those related to growth, feed efficiency, and carcass composition. Although genomic selection has substantially improved EBV accuracy over the past decades, the incorporation of additional layers of biological information may further enhance predictive performance. In this context, the rumen microbiome has gained increasing attention as a biologically meaningful intermediate phenotype that may partially mediate the relationship between host genotype and complex production traits. Therefore, integrating metagenomic information into genomic evaluation frameworks represents a promising strategy to refine selection decisions. The aim of this study was to evaluate whether the inclusion of rumen metagenomic data improves predictive accuracy compared to a conventional genomic best linear unbiased prediction (GBLUP) model, using a genomic-omic BLUP (GO-BLUP) approach for feed efficiency and carcass-related traits in commercial beef cattle. Data included 1,458 British Blue × Holstein crossbred animals genotyped for 65,782 SNPs, aged 213 ± 33 days at the start of the trial, all fed the same commercial diet and evaluated at a commercial test station. Feed intake and body weight were recorded during 4-week trial, allowing the estimation of feed conversion ratio (FCR), average daily gain (ADG), daily feed intake (DFI) and residual feed intake (RFI). At the end of the trial, intramuscular fat (IMF), eye muscle area (EMA), and subcutaneous fat thickness (SFT) at the 12th–13th rib were measured by ultrasound, rumen samples were collected via stomach tube for whole-metagenome sequencing, and carcass weight (CW) was recorded at slaughter. Predictive performance was assessed using a repeated external validation scheme in which 80% of the animals were randomly assigned to the training set and the remaining 20% constituted the validation set with masked phenotypes, replicated across 100 random partitions. All performance trait models included sex and batch as fixed effects, and diet composition variables and age as covariates. First, a GBLUP model with a genomic random effect was fitted. Subsequently, a two-step GO-BLUP approach was implemented. In the first step, a GBLUP model including genomic and microbial random effects was fitted to estimate direct genomic and microbiome variances using the GRM and MRM matrices. Estimated microbial values were then used as a phenotype in a second model including sequencing depth as a fixed effect and a genomic random effect to estimate microbiome-mediated genomic variance, thereby partitioning genetic and environmental components. Empirical predictive ability was calculated as the correlation between adjusted phenotypes and EBVs in the test set. Across traits, GO-BLUP yielded higher predictive ability than GBLUP in animals with masked phenotypes for ADG, with a mean improvement of +20% ($p < 0.001$), +8% for DMI ($p = 0.003$), and +10% for FCR ($p = 0.015$). MGs explaining the largest proportion of genetic variance for ADG and DMI were UBA2810 and Dialister. No relevant differences were observed for EMA, CW, SFT, IMF, DFI, or RFI. These results suggest that incorporating rumen metagenomic data improved prediction accuracy for efficiency traits, supporting microbiome-informed genomic evaluation through GO-BLUP.

Evaluating the Contribution of Microbiome Information to Genomic Prediction for Growth, Feed Intake, and Carcass Traits in Angus Cattle

R. Magalhaes Da Costa[1], F. Bussiman[1], A. Garcia[2], K. Retallick[2], D. Lourenco[1], J. Lourenco[1]
[1] University of Georgia, Department of Animal and Dairy Science, 425 River Rd, 30602 Athens, United States,
[2] Angus Genetics Inc, American Angus Association, 3201 Frederick Ave, 64506 Saint Joseph, United States

Incorporating ruminal and gut microbiome information into genomic models enables partitioning of genetic variation into host and microbiome contributions, potentially enhancing the accuracy of genetic evaluations. We aimed to evaluate the impact of including ruminal and fecal microbiome similarity matrices in BLUP-based models for predicting genomic breeding values (GEBV) in American Angus cattle. Fecal and ruminal samples were collected from 1,460 yearling Angus bulls across eight U.S. feed efficiency centers. After data editing, samples from animals not registered with the American Angus Association and those that did not meet quality standards for microbiome analysis were removed. A total of 906 (ruminal) and 913 (fecal) animals, born between November 2020 and May 2022, remained for further analyses. Amplicon sequence variant (ASV) abundances were inferred using the DADA2 and Greengenes2. After rarefying samples to 10,000 reads and filtering ASVs with total abundance <1,200 and prevalence <5%, 1,451 ruminal and 1,388 fecal ASVs were kept for the analysis. Genomic prediction was performed for four economically important traits: weaning weight (WW), post-weaning gain (PWG), dry matter intake (DMI), and ultrasound backfat thickness (uFAT). Predictive performance of GEBVs was evaluated using the linear regression (LR) method implemented in validationf90 in single-trait models, including fixed effects of contemporary group, age classes (for DMI), overall mean, and birth year. The focal group was comprised of animals born in April and May 2022, totaling 85 animals for the ruminal group and 86 for the fecal group. Four models were considered: GBLUP, additive genetic effects only (u); GMBLUP, additive genetic effects not mediated by the microbiome (ur); mBLUP, which uses the predicted microbiome effects from the GMBLUP model as pseudo-phenotypes to estimate additive genetic effects mediated by the microbiome (um), and COMB, combining microbiome-mediated and non-mediated components (ut = ur + um). In both ruminal and fecal datasets, GBLUP and GMBLUP showed similar predictive performance, indicating that the host genetic component not mediated by the microbiome accounts for most of the stable signal captured in genomic prediction. The BLUP model showed reduced accuracy and greater dispersion, particularly for PWG and uFAT, suggesting that microbiome-mediated effects have limited predictive power when considered alone. However, combining microbiome-mediated and non-mediated effects improved prediction stability. The COMB model consistently achieved accuracies comparable to or slightly higher than those of GBLUP, with low bias and dispersion across most traits. Improvements were more evident for WW and PWG, whereas DMI and uFAT showed limited gains from microbiome inclusion. Overall, the results indicate that microbiome information alone does not improve genomic prediction, but when combined with host genomic effects, it provides greater stability, supporting the microbiome as an additional biological factor influencing economically important traits in Angus cattle.

Integrating functional SNVs with mRNA isoform expression in A1A1 and A2A2 Holstein dairy cows

L. Jiménez Montenegro[1], O. Urrutia Vera[2], Á. Cánovas[1]
[1] University of Guelph, Department of Animal Biosciences, 50 Stone Road East, N1G 2W1 Guelph, ON, Canada, [2] Public University of Navarre (UPNA), Department of Agricultural Engineering, Biotechnology and Food, ETSIAB, Campus Arrosadia s/n, 31006 Pamplona, Navarre, Spain

The A2 β-casein variant has gained considerable interest due to proposed health benefits, contributing to the increasing frequency of the A2A2 genotype in dairy herds. Although the A1/A2 substitution in the β-casein gene (CSN2) does not directly modify gene regulation, previous studies have reported differences in gene expression, especially at the mRNA isoform level, between A1A1 and A2A2 cows. Thus, this study aimed to investigate whether Holstein cows with A1A1 and A2A2 β-casein genotypes exhibit distinct single nucleotide variants (SNVs) using RNA-Seq data derived from milk fat globule (MFG). Variant calling was performed using CLC Genomics Workbench, and were classified according to their predicted effects: (i) amino-acid change (AAC), (ii) splice site effect (SSE), and (iii) variants exhibiting both effects. In A1A1 cows, 3,033 SNVs were predicted to generate AAC, 170 SNVs were predicted to cause SSE, while 59 SNVs showed both effects. In A2A2 cows, 3,256 SNVs were predicted to generate AAC, 202 SNVs to cause SSE, and 75 SNVs to exhibit both effects. The Ensembl Variant Effect Predictor (VEP) was used to functionally annotate all variants according to their predicted consequence types. Regarding SNVs leading to AAC, only those with SIFT (Sorting Intolerant From Tolerant) < 0.05 were retained, as these values indicate a high probability of affecting protein function. SNVs leading to SSE were integrated with previously analysed differentially expressed (DE) mRNA isoforms, and only those affecting genes with at least one DE isoform were further analysed. Functionally relevant genes affected in A1A1 group of cows were associated with mitochondrial oxidative phosphorylation (OXPHOS) (NDUF subunits, COX7A2 and ATP5PF), together with genes related to mitochondrial integrity and function (SLC25A44, PTCD1, PISD and IMMT) and lipid metabolism (ACSL1, MFGE8). A2A2 genotype-associated variants were also identified in genes related to mitochondrial function (OPA1, PTCD1, SLC25A46, NSUN3 and SIRT4), lipid metabolism (CPT1B, LPIN1, FASN, SPTLC2), as well as vesicle trafficking and secretory pathways (MVB12B, LRRK2, ABCA2, ABCA5, SEC31A and ABCG2). A deeper functional interpretation of these genotype-associated SNVs in expressed regions of the genome will clarify their biological relevance and the pathways potentially affected in the context of selective breeding towards the A2A2 genotype in Holstein dairy cows.

Effectiveness of DNA Sequencing and Biochemical Methods in Characterizing Bovine Milk Protein Variants

Bovine milk proteins are highly polymorphic, and several variants are known to influence milk processing properties and nutritional quality. Milk protein variants can be identified either through DNA sequencing or biochemical analysis, but concordance between these approaches has not been extensively studied. This study aimed to evaluate the effectiveness of DNA-based predictions and biochemical analyses of milk samples for the identification of milk protein variants. To achieve this, we compared predictions based on whole-genome sequencing data with average coverage of 10× with RP-HPLC analysis of milk samples from 178 cattle originating from different European and African breeds. LC-MS was subsequently used for a subset of the milk samples to confirm new DNA-predicted variants and resolve additional isoforms detected by RP-HPLC. Our results show that DNA sequencing shows an high accordance of 92%-97.2% compared with RP-HPLC for the major known protein variants. However, SNP read depth had a substantial impact on the discordance and on the call rate. In our data set a depth of four reads represented a minimum requirement for reliable protein variants genotyping. Moreover, 6 out of 10 DNA-predicted rare variants were confirmed using LC-MS, while the remaining 4 variants could not be validated successfully due to insufficient read depth at corresponding SNPs or due to sequencing errors. Finally, protein analysis also identified variants (αS1-CN A and β-CN A3) that were not detected by DNA sequencing due to the difficulties in identifying newly splice variants and low-quality SNP calling, respectively. This study provides a systematic evaluation of the concordance between DNA-based inference and biochemically protein-level identification of milk protein variants. We demonstrate that moderate DNA sequencing coverage (~10×) achieves comparable agreement of more than 92% compared with RP-HPLC. However, accurate identification of protein variants from DNA sequence data remains challenging, especially for low quality SNP calling and incomplete functional annotation of splice variants. Increasing the stringency of the read depth can reduce the discordance but also decreases the call rate. Keywords: Protein variants, DNA sequencing, RP-HPLC, LC-MS

Multi-evidence driven triage of candidate genes for feather pecking behaviour in chickens

C. Falker-Gieske[1,2], J. Bennewitz[3], J. Tetens[1,2]
[1] Georg-August-University Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, [2] Georg-August-University Göttingen, Center for Integrated Breeding Research, Albrecht-Thaer-Weg 3, 37077 Göttingen, Germany, [3] University of Hohenheim, Institute of Animal Science, Garbenstr. 17, 70599 Stuttgart, Germany

Feather pecking in laying hens is a complex, multifactorial behavioural trait with a genetic component that significantly impairs animal welfare and increases energy requirements, resulting in lower resource efficiency. Since divergent selection for high and low feather pecking behaviour led to the establishment of two distinct lines with very high and no propensity for the behaviour, respectively, a causative connection between genetics and the behaviour is evident. Hence, we hypothesise that functional genetic variants that alter the structure, stability, or expression of proteins in key neurobiological pathways are likely to influence individual variation in feather-pecking behaviour in laying hens. Our objective is to prioritise a short list of candidate haplotypes for experimental validation, recognising that many protein-altering variants may be phenotypically silent. For this, whole-genome sequences from hens of high and low feather-pecking lines (>15 generations of selection; n=49) were contrasted using population differentiation to identify strongly diverged loci. Haplotype-aware protein sequences were reconstructed, and candidates were ranked using an integrated evidence score. Previously called SNPs, small indels (<50 bp), structural variants and tandem repeats were analysed by computing Fixation indices (FST) with PLINK. Haplotype-aware protein prediction was performed with Haplosaurus (Ensembl VEP). Variant consequences were annotated with VEP/snpEff; missense impact with SIFT 4G and PROVEAN; splice effects with SpliceAI; disordered regions with IUPred3 and motif mapping with ELM. Protein structures/complexes were modelled with AlphaFold3 and stability/interface effects estimated with FoldX; interaction partners were obtained from STRING; tissue expression context from Bgee and Expression Atlas. Evidence signals were standardised and combined as a weighted score. Differentiation was quantified by per-variant FST; highly differentiated variants were defined as FST>0.9 and summarised descriptively. Across 49 sequenced hens, 125,000 highly differentiated variants (FST>0.9) were detected between lines, including 681 protein sequence–altering haplotypes (up to 14 missense variants per haplotype as well as indels). SpliceAI predicted 66 variants with potential splice disruption. Preliminary joint analysis of all datasets led to the production of a prioritised list of candidate genes for feather pecking behaviour, with the top candidate gene encoding the Apolipoprotein B (APOB). The APOB haplotype harbours 14 missense mutations, which led to a significant score in four of the above mentioned analyses. Besides being the highest-scoring gene in this study, APOB has been linked to aggressive behaviour in humans by two independent studies. This makes APOB a top candidate for experimental validation of its causality in feather pecking behaviour. This multi-evidence, tool-based triage integrates sequence, structure, regulatory and biological-context evidence to prioritise a manageable set of neurobiologically plausible candidates for functional testing, explicitly addressing that structural changes alone may not translate into behavioural phenotypes. The approach is species independent and is applicable to a wide range of behavioural disorders and can be easily adapted to any complex genetic disorder with a measurable phenotype.

Utilising genotype and transcriptome information for feather pecking analysis in laying hens

U. S. T. Yarra[1], V. Haas[2], J. Bennewitz[2], J. Tetens[1]
[1] Georg-August-Universität Göttingen, Functional Breeding, Burckhardtweg 2, 37077 Göttingen, Germany, [2] University of Hohenheim, Animal Genetics and Breeding, Garbenstr. 17, 70599 Stuttgart, Germany

Feather pecking in laying hens represents a significant welfare concern and leads to substantial economic losses. Although genome-wide association studies have identified genomic regions linked to this behaviour, pinpointing the underlying causal genes remains difficult. Transcriptome-wide association studies (TWAS) address this challenge by combining genotype data with gene expression profiles to evaluate whether the genetically regulated component of gene expression is associated with the trait. We applied an individual-level TWAS framework to feather pecking to identify candidate genes and biological pathways that may mediate genetic risk, while also evaluating multiple TWAS modelling approaches to ensure robust and reliable inference. We will additionally integrate genotype and transcriptome data into mixed linear models to partition phenotypic variance into mentioned components and assess predictive performance through cross-validation based on genomic and transcriptomic similarity. Data were derived from a half-sib (HS) population from the 15th generation of a long-term feather pecking selection experiment of Lohmann Selected Leghorns. Individual-level genotype and RNA-seq data from 48 birds were used to train cis-genetic prediction models of gene expression (variants within a defined window around each gene) following genotype quality control and expression normalization. The genetically regulated component of expression was then imputed into an independent set of 441 genotyped birds from the same population and evaluated for association with feather-pecking phenotypes. Multiple testing was addressed using Bonferroni correction. In this analysis, thousands of genes yielded usable expression prediction models and were subsequently evaluated in the association cohort (2,990 genes with BLUP; 8,421 with nonparametric Bayesian DPR; and 9,884 with elastic net). The number of Bonferroni-significant genes differed across models (472, 2,172, and 1,971 respectively), indicating that TWAS findings may be sensitive to modelling choices when the training sample size is small (n=48). These preliminary findings support the utility of TWAS for prioritizing candidate genes, while underscoring the need for further enhancement. We will enhance adjustment for covariates, population structure, and relatedness to ensure reliable results. Genes supported across analyses will be prioritized and interpreted through enrichment and functional context. The expected outcome is a reproducible workflow and candidate genes for feather pecking in chickens and supporting welfare-oriented breeding and management decisions.

From genotype to phenotype: mapping shared regulatory architecture of cattle metabolome and transcriptome

P. K. Chitneedi[1], G. C. M. Moreira[5], C. Li[3,6], D. Fischer[4], C. Charlier[2], G. Plastow[3], J. Vilkki[4], R. Weikard[1], C. Kühn[7,8]

In genomic studies identifying the pleiotropic genetic regulators helps to elucidate the molecular mechanism underlying complex phenotype and facilitate the identification of functional causal variation. These kinds of genetic regulators can be identified by colocalizing the regions from multiple genomic studies. Colocalization is a robust statistical approach used to determine whether a shared causal variant underlies associations across multiple omics layers, effectively distinguishing pleiotropy from coincidental linkage. In this study, we performed colocalization analysis of metabolite quantitative trait loci (mQTL) derived from 147 plasma metabolites in 325 individuals of Charolais × German Holstein crossbred population and expression quantitative trait loci (eQTL) from RNA-seq of liver tissue in 357 samples, across diverse cattle breed populations. For both datasets the genotype data consists of whole genome sequence imputed genotypes. The colocalization analysis was carried using the coloc.abf() function from R package coloc. This function assumes a single causal variant for each trait and calculates the posterior probabilities of different configurations using a Bayesian approach. For each selected region across both datasets, the results summary generates a vector of the common SNPs tested per region and five posterior probabilities for causal association ranging from PP.H0 to PP.H4, where PP.H0 represents the probability of having no causal variant and PP.H4 the probability of having a causal variant. For colocalization we considered only the significant loci ($P<5\times10^{-8}$) associated to different plasma metabolites from mQTL dataset. Similarly, the eQTL dataset comprises summary statistics of significant variants (adjusted $P<0.005$) derived from gene-level cis-eQTL conditional analysis with multiple independent signals per gene which were based on conditional ranking. To perform the colocalization, coloc.abf() was provided with significant SNPs and a 250 kb buffer on either side, ensuring the inclusion of the full genomic context for both mQTL and eQTL signals. We cross-referenced the allele assignments for each variant between the two datasets to confirm concordance and maintain data integrity. We identified 42 significant colocalized regions (PP.H4>0.8). Most of these are located on BTA-11 between 3.2–3.8 Mb and BTA-15 between 72–82 Mb. In previous studies a significant QTL was identified at BTA-11 3.6 Mb which was associated to CNAG3. The CNGA3 has been identified as a key marker for feed efficiency in beef cattle, likely influencing Residual Feed Intake (RFI) through the enrichment of multiple ion transport and signal transduction pathways. The BTA-15:72–82 Mb region is identified as a QTL hotspot in CattleQTLdb, containing eight loci associated with average daily gain, along with two loci related to traits, serotonin levels and antral follicle count. Future research will investigate this region further, to uncover potential regulatory pathways and networks influencing the metabolites and genes expressed in these cis-eQTL regions.

Comparative profiling of the bovine plasma proteome using Olink proximity extension assay and LC–MS/MS before and after calving

M. Bhati[1,2], E. Paxton[1], L. Morrison[1], A. Tenesa[1]
[1] Roslin Institute, University of Edinburgh, Easter Bush Campus, EH25 9RG Midlothian, United Kingdom, [2] Department of molecular life sciences, University of Zurich, Winterthurerstrasse 190, 8057 Zurich, Switzerland

The transition period around parturition in dairy cattle involves major metabolic, endocrine, and immune adaptations reflected in the plasma proteome. However, the extent to which different proteomic platforms capture these changes in bovine plasma remains unclear. The objective of this study was to compare a human-targeted proximity extension assay (Olink Explore 3072) with discovery-based liquid chromatography–mass spectrometry (LC–MS/MS) for plasma protein detection and differential expression analysis in dairy cows before and after calving. Plasma samples from eight cows before and after calving were analysed using the Olink Explore platform (targeting 2,932 human proteins) and LC–MS/MS. Olink data were quality-controlled and filtered to retain proteins detected in ≥50% of samples. LC–MS/MS data were generated using a data-dependent acquisition (DDA) workflow and processed with PEAKS X Pro for label-free quantification, resulting in 300 quantified proteins ≥ 2 unique peptides. To ensure statistical consistency, differential protein abundance for both platforms was evaluated using linear models implemented in the limma package in R, including cow identity as a blocking factor to account for paired samples collected before and after calving. Using Olink, 925 proteins were detected, of which 22 showed significant differential abundance (FDR < 0.05) with 12 proteins increased after calving (e.g., FGF21, NOS2 and CHGA) and 10 decreased (e.g., OXT, DKK1 and COL9A1). Cross-species ortholog mapping identified 865 bovine orthologs among the detected proteins, with 795 showing ≥70% sequence identity between human and bovine proteins, indicating strong conservation. In comparison, LC–MS/MS identified six significant differential abundance (FDR < 0.05), including APOM, GC, CPN1, AGT and APOF, which were more abundant after calving, while VNN1 showed higher abundance before calving. Notably, GC (vitamin D–binding protein) has shown to be associated with mastitis susceptibility in dairy cattle. Only fourteen proteins were quantified by both technologies. Comparison of fold changes revealed moderate agreement (60%) in the direction of change between platforms. Differences between platforms reflect their distinct analytical principles. Olink uses antibody-based targeted detection and captures low-abundance regulatory proteins, whereas LC–MS/MS provides unbiased identification of endogenous bovine proteins but preferentially detects higher-abundance plasma proteins; species-specific differences between human assay targets and bovine proteins may influence Olink detection. Together, the results demonstrate that Olink and LC–MS/MS provide complementary insights, improving the characterization of the bovine plasma proteome during critical physiological transitions. Integrating targeted and discovery proteomics approaches, therefore offers a powerful strategy for improving characterization of physiological changes around calving and identifying candidate biomarkers relevant to dairy cattle health.

Genetic Score Omics Regression to Map Genes Underlying Stillbirth and Gestation Length

M. Zölch[1], A. M. Križanac[2], C. Schmidtmann[3], H. Alkhoder[3], J. Tetens[2], J. Bennewitz[1], M. E. Goddard[4,5], R. Xiang[4,5,6]

Since the introduction of SNP-chip genotyping, the understanding of health and yield traits in farm animals has markedly improved. Transcriptomics represents the next layer of the omics cascade, providing direct measures of gene activity. Recent efforts in animal science have focused on aggregating public RNA-seq data across tissues to create larger, more powerful datasets. A notable example is CattleGTEx, a multibreed collection of RNA-seq data and imputed genotypes in cattle. To link gene expression data and quantitative traits, the Transcriptome-Wide Association Study (TWAS) is a common method. It trains a prediction model of genetically regulated expression in a usually small group of animals with measured gene expression and predicts gene expression levels into a larger group of phenotyped animals, where associations between predicted expression and phenotypes are tested. The recently introduced Genetic Score Omics Regression (GSOR) method is a reversed approach and uses SNP-effects trained on a much larger sample size for phenotype prediction and predicted local genomic breeding values (EBVs) into samples with assayed gene expression. Then, GSOR estimates the correlation between measured gene expression and estimated phenotypes based on gene-specific local EBVs. We applied GSOR to the direct and maternal effects on stillbirth and gestation length in German Holsteins. The expression sample sizes in CattleGTEx for the tissues of blood, liver and uterus varied between 359 and 945. The number of cows with de-regressed proofs ranged from 36,502 to 192,880. Based on these and a set of imputed and LD-pruned WGS genotypes, BayesR3 was used for effect estimation of approximately 2.5 million SNPs effects for stillbirth and gestation length traits. Local EBVs were then computed based on the effects of SNPs located in the gene and within ±1 Mb. Correlations between these local EBVs, and the CattleGTEx gene expression with an FDR-corrected p-value < 0.05 were deemed significant. Results were further filtered for a local EBV variance above the 75th percentile, retaining only genes with meaningful variation. Summary-based Mendelian Randomization (SMR) was used as a third filtering step to prioritize genes with evidence for causality. The remaining trait-associated, potentially explanatory, genes were interpreted based on PubMed (NCBI). Most identified genes were associated with gestation length and only a few with stillbirth. This was expected based on the lower heritability of stillbirth compared to gestation length. The biological relevance of the associations found by GSOR is, for example, supported by correlated genes in the liver, that have been associated with fat metabolism by previous studies. Another correlation was identified between a gene's expression in blood and the maternal effect on gestation length. Here, the literature suggests an important role in placental nutrient transport with effects on birth weight. In summary, we successfully applied GSOR for stillbirth and gestation length, identifying genes and underlying metabolic pathways affecting these traits.

Transcriptomic signatures associated with intramuscular fat deposition in the Black Slavonian pig

B. Lukic[1], G. Lipavic[2], M. Bulaic[4], I. Curik[3,5], Z. Radisic[1], R. Luzaic[1], N. Raguz[1]
[1] Faculty of Agrobiotechnical Sciences Osijek, Department for Animal Production and Biotechnology, Vladimira Preloga 1, 31000 Osijek, Croatia, [2] Central Finance and Contracting Agency, Ulica grada Vukovara 284, 10000 Zagreb, Croatia, [3] Faculty of Agriculture, Department of Animal Science, Svetošimunska cesta 25, 10000 Zagreb, Croatia, [4] Inspecto Ltd., Vukovarska cesta 239, 31000 Osijek, Croatia, [5] Hungarian University of Agriculture and Life Sciences - Institute of Animal Sciences, Kaposvar Campus, Guba S. u. 40., 7400 Kaposvar, Hungary

Intramuscular fat (IMF) is a key determinant of pig quality, strongly influencing sensory attributes such as flavor, tenderness, and juiciness. Although the molecular mechanisms regulating IMF deposition have been extensively studied in modern commercial pig populations, considerably less information is available for traditional and locally adapted breeds. Native pig populations often possess distinct metabolic and physiological characteristics, making them valuable models for investigating alternative regulatory pathways involved in lipid accumulation in skeletal muscle. The present study explored transcriptomic differences associated with divergent IMF levels in the Black Slavonian pig, an indigenous Croatian breed recognized for its high-quality meat products. Muscle tissue samples from the Longissimus thoracis et lumborum were obtained from fourteen animals displaying contrasting IMF content. The IMF percentage was quantified from the same muscle region 24 hours post mortem using the Soxhlet extraction procedure. RNA sequencing was applied to profile gene expression patterns between the two phenotypic groups. Differential expression analysis revealed over 500 genes showing significant expression differences ($p \leq 0.05$), of which 457 remained significant after adjustment for multiple testing. Animals with higher IMF content showed increased expression of genes involved in lipid metabolism and adipocyte differentiation, including SCD, ADIPOQ, CIDEC, and FABP4, as well as activation of regulatory pathways linked to PPAR signaling and fatty acid synthesis. Conversely, several genes associated with muscle fiber organization and oxidative metabolism were relatively suppressed in the high-IMF group. Functional enrichment analyses indicated that IMF accumulation in skeletal muscle is associated with coordinated regulation of multiple biological processes. In addition to lipid metabolic pathways, significant enrichment was observed for pathways related to extracellular matrix remodeling, vascular development, and cell–cell signaling. Several extracellular matrix components (e.g., LAMA1, TIMP4) and angiogenesis-related genes (FGF2, NRP1) displayed elevated expression levels, suggesting that the expansion of intramuscular adipocytes is accompanied by structural remodeling of muscle tissue and enhanced vascularization. Also, some of the highly ranked differentially expressed genes have not previously been widely implicated in IMF deposition in pigs. Among them, EHD, NRG4, UTRN, FLNA, and HMCN1 may represent novel candidates potentially involved in processes such as membrane trafficking, paracrine communication between adipocytes and muscle fibers, cytoskeletal organization, and extracellular matrix dynamics. These findings suggest that IMF regulation in local pig breeds may involve partially distinct molecular mechanisms compared with those described in intensively selected commercial lines. The results expand current knowledge on the molecular architecture of meat quality traits in indigenous breeds and highlight potential candidate genes and pathways that could be considered in future breeding programs aimed at improving pork quality while preserving valuable genetic diversity.

Genetic and genomic strategies for advancing sustainable beef-on-dairy systems

D. Lourenco[1], M. Bermann[1], A. Cesarani[1,2], I. Misztal[1]
[1] University of Georgia, Animal and Dairy Science, 425 River Road, 30602 Athens, United States, [2] Università degli Studi di Sassari, Dipartimento di Agraria, Viale Italia 39a, 07100 Sassari, Italy

Although beef-on-dairy is not a new practice, its adoption has increased recently with the widespread availability of sexed semen. In this system, the best dairy females are used to generate replacement heifers, whereas beef semen is used on the remainder to enhance the value of surplus calves. This practice has strengthened the connection between the dairy and beef sectors; however, the initial choice of beef semen was not driven by genetics. Incorporating genetic and genomic strategies into beef-on-dairy programs is essential to ensure the long-term sustainability of the system. As breeding companies and breed associations began designing breeding programs or selection indices specific to beef-on-dairy, the performance of crossbred products improved to the point that consumers have a similar experience to that of traditional beef products. While carcass quality is a primary concern for the beef sector, dairy producers are particularly concerned about fertility, calving performance, and calf health. Fertility concerns may have arisen because beef sires were frequently used in cows already identified as problem breeders. In a study on conception rate (CR) in the USA, we observed mean CR of 33.77% and 34.29% for breedings with Angus and a Holstein sires mated to HO cows, respectively. For matings with Holstein heifers, the CR were 52.96% and 55.34%, in the same order. The average number of services was 42% and 47% higher for Holstein cows and heifers mated to Angus bulls, respectively. Because crossbreeding can influence gestation length as well as calf weight and size, potentially affecting the productive life of dairy cows, calving ease (CE) has become an important trait in beef-on-dairy systems. When investigating the genetic background of CE in beef-on-dairy crosses, we observed that, on average, the incidence of unassisted calvings in the first (first three) lactation was 83% (88%) for Holstein and 86% (90%) for Jersey cows bred to Angus, Charolais, and Simmental beef bulls. The highest proportion of assisted calvings occurred in Holstein heifers bred to Charolais bulls (27%) and Jersey heifers bred to Simmental bulls (22%). Overall, Holsteins showed a higher incidence of assisted calvings. Among the top 5% and bottom 5% of bulls based on genetic evaluation, the proportion of progeny with easy calving was 91% and 81%, respectively, demonstrating the value of estimated breeding values for identifying superior bulls. However, as the heritability of CE is low, at around 0.014, genetically improving CE would require large amounts of data and genomic information. Some of the issues contributing to the low heritability and, therefore, slower genetic progress include: the lack of data sharing between the dairy and beef sectors, which results in a complete pedigree on one side but a shallow pedigree on the other; the missing pedigree structure, which prevents information from flowing among animals; the complete disconnection between the beef and dairy pedigrees; and difficulty in sharing genomic information between the sectors. In this talk, we will discuss genetic and genomic strategies to optimize beef-on-dairy systems while balancing the interests of both the dairy and beef sectors. Particular attention will be given to opportunities for improving genetic evaluations through large-scale phenotyping, stronger pedigree integration, genomic selection, and cross-industry data sharing.

Balancing profit and calving performance: New breeding values for Beef-on-Dairy sires

C. Schmidtmann[1], A. Rolfes[2], M. Wobbe[1], L. Polman[1], D. Adekale[1]
[1] IT Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany, [2] German Livestock Association (BRS), Adenauerallee 174, 53113 Bonn, Germany

The use of Beef-on-Dairy (BoD) matings has expanded markedly in recent years. In Germany, BoD accounted for approximately 25% of all inseminations in 2025. Economic incentives include comparatively low semen costs and higher market prices for crossbred calves. In combination with female-sexed dairy semen and herd genotyping, BoD enables targeted mating strategies that enhance genetic gain in dairy herds while generating additional revenue. Until recently, beef sire selection for BoD matings was based mainly on phenotypic information. In 2025, Germany implemented new conventional breeding values for beef sires in dairy herds to support more informed and precise selection. New traits comprise calf weight and calf revenue, complemented by the direct calving traits calving ease and stillbirth. Data foundation for the breeding values of calf weight and calf revenue consisted of auction records from 116,419 BoD calves born between 2016 and 2025 with recorded sale weight and realized revenue at 14 to 90 days of age. Only calves sold on farms with complete records were included. Variance components were estimated using a bivariate multi-breed animal model with a five-generation pedigree. Fixed effects included age class × birth year × sex, herd × birth year and sire breed. Multi-breed, multi-trait breeding value estimation was subsequently performed, and the sire breed effect was incorporated into the final breeding value of each sire. The economic-related breeding values are reported on a natural scale: kilograms (kg) for calf weight and euros (€) for calf revenue. Calving-related breeding values are currently based on the genetic evaluation for Holstein cattle and are expressed on a relative breeding value scale. All BoD breeding values are calculated on a specific reference basis comprising BoD calves born within the last five years, ensuring comparability within and across breeds. The basis includes the main BoD breeds: Belgian Blue, Simmental cattle (beef type), Angus, Limousin, Charolais, Uckermärker, Blonde d'Aquitaine and INRA 95. Published breeding values reveal clear breed differences. Across breeds, mean breeding values relative to the BoD base population were 0.2 kg for calf weight and −32.6 € for revenue. Within-breed means ranged from −7.4 kg (Angus) to 4.2 kg (Blonde d'Aquitaine) for weight and from −154.1 € (Angus) to 39.1 € (Belgian Blue) for revenue. Reliability was high, averaging 89% for weight and 85% for revenue. Correlations between breeding values for calf weight and calving difficulty ranged from −0.17 to −0.70, indicating antagonistic relationships between growth potential and calving ease. For calf revenue, correlations with calving ease ranged from −0.33 to 0.23. These results confirm breed-specific differences and highlight the trade-off between economic and functional traits. The newly implemented BoD breeding values provide a robust tool for optimized beef sire selection in dairy herds, promoting economically valuable calves while safeguarding calving performance.

Early lactation prediction of extended lactation milk yield class using random forest models in pasture-based dairy systems

S. L. Bird[1,2], N. Lopez-Villalobos[1], C. J. Andrews[1], S. J. Hendriks[2], J. P. Edwards[2]
[1] Massey University, School of Agriculture and Environment, Tennent Drive, 4410 Palmerston North, New Zealand, [2] DairyNZ, Millpond Lane, 7608 Lincoln, New Zealand

In dairy cows, extended lactations (EL; milking for a period longer than the standard seasonal pattern) are a potential option for reducing the number of calvings in a cow's lifetime, and therefore, the number of surplus, non-replacement calves produced annually. However, the suitability of individual cows for an EL system is variable as their total milk production must align with the associated operational costs. The classification of high and low yielding animals could inform suitability of individual cows or a herd for maintaining a profitable farm business under EL. Early prediction of total EL milk yield is especially important within a seasonal pasture-based system, where breeding occurs within a seasonally concentrated timeframe and decisions to delay breeding, are made during early- to mid-lactation. Decisions for EL systems are made largely on a herd-level basis, with limited test-day data available before determining intended mating, and therefore EL cows. Earlier work indicates that there is potential to use early lactation data to predict total milk yield, however, to our knowledge, no studies in pasture-based cows have further attempted to build these models. Machine learning methods such as random forest techniques could be used to develop predictive models for cow performance. The aim of this study was to use early lactation curve features to predict cows as high- or low-yielding when managed for extended lactation. Milk yield records were obtained from dairy cows in New Zealand from a range of ages (2 to 10 years) and predominantly Holstein, Jersey and Holstein-Jersey crossbred breeds that had completed a 415-to-720-day lactation. In total, 5,226 EL records with at least seven herd tests were modelled with fifth order Legendre polynomials and daily yields estimated from individually modelled lactation curves. High and low yielding classes of average daily milk yield were determined based on a range of top and bottom percentiles of average daily milk yield for the length of each EL, then the EL records was split into training (70%) and test (30%) datasets. Several random forest models were then trained to predict EL yield class using animal characteristics, average daily herd production and modelled lactation curve features from the first 100 days. Variable importance measures were used to assess which aspects of the early lactation curve shapes were most strongly associated with EL yield performance. The performance of each model was evaluated using the test dataset and a confusion matrix and the best performing model selected. The models provided strong classification performance (balanced accuracy ~ 90%) indicating that early lactation features and cow-level characteristics such as breed and age, could provide insight into EL performance. Total yield to 50 and 100 days were also important features, suggesting that higher yielding cows early in lactation were likely to have a greater than average daily yield that can be sustained throughout the remainder of the lactation. Another predominant feature of importance was the average daily yield of the herd to 100 days, indicating that some herds were more likely to have suitable cows for EL than others. These results are consistent with prior research and support the potential use of machine learning methods to assist early decision making for EL selection in pasture-based systems. Prediction of suitable EL animals would help make informed decisions regarding breeding management and strategic use of EL at an individual cow and herd level.

Comparative Machine Learning for predicting late-lactation productivity in dairy cows.

Y. Aarts[1], E. Burgers[2], E. Saccenti[3], R. Torres[4], R. Goselink[2], A. Van Knegsel[1]
[1] Wageningen University & Research, Adaptation Physiology Group, PO Box 338, 6700 AH Wageningen, Netherlands, [2] Wageningen University & Research, Wageningen Livestock Research, PO Box 338, 6700 AH Wageningen, Netherlands, [3] Wageningen University & Research, Laboratory of Systems and Synthetic Biology, PO Box 338, 6700 AH Wageningen, Netherlands, [4] Wageningen University & Research, Artificial Intelligence Group, PO Box 338, 6700 AH Wageningen, Netherlands

Extended lactations offer opportunities to increase cow lifespan by reducing the frequency of risk events related to calving, improve farm efficiency by reducing the labour associated with calving, and improve total milk produced per unit of time by reducing the relative number of dry-days. However, an extended lactation also has potential drawbacks: some cows may exhibit low milk production in late lactation or accumulate excessive body condition, which has been associated with impaired metabolic status after subsequent calving. Moreover, since pregnancy lasts around 9 months, insemination decisions must be made well in advance, under substantial uncertainty about future milk production. Conventionally farmers start inseminating their cows from day ~60 in lactation onwards. Successful implementation of an extended lactation management therefore requires timely selection of suitable cows and decision support when to inseminate them. Thus, using the cow information available before 60 days in lactation to predict lactation outcomes to select the suitable cows for an extended lactation could be valuable to farmers. Predicting future lactation performance from early lactation milk production was formulated as a time-series classification task. Daily milk yield during the first 60 days in milk (DIM) was used as input to predict late lactation production, defined as the cumulative milk yield between 250 and 257 DIM. This period was used as a proxy for lactation outcome while minimizing potential gestation effects. Lactations where classified using a predefined production threshold, separating cows for which extended lactation is advisable from those for which conventional insemination strategies are preferred. In this study, seven established time-series classification methods were evaluated on data consisting of a period of ~4 years from Dutch commercial dairy farms including 6226 lactations of at least 264 days which is the minimum length to be considered in this experiment. The following models were selected: Time-series forest classifier.Bag of Patterns Classifier.K-Nearest Neighbour time series classifier.Learning Shapelet Classifier.Ensemble of Bag of Symbolic Fourier Approximation Symbols. The Elastic Ensemble of time series distance measures.Hierarchical Vote Collective of Transformation-based Ensembles V2.These models represent distinct time-series classification paradigms: whole sequence-based, interval-based, shapelet-based, dictionary-based and hybrid approaches, enabling a structured comparison of how different temporal representations contribute to predictive performance. Model performance was evaluated using 5 fold grouped cross-validation with folds defined at farm level to prevent data leakage. Across all evaluated thresholds, the Time-series forest classifier, the interval-based paradigm, consistently achieved the highest predictive performance (accuracy: 0.852 ± 0.043, f1-macro: 0.607 ± 0.046, brier loss: 0.111 ± 0.026, AUC: 0.778). In conclusion, the interval-based representations of early lactation milk yield captured the most informative temporal characteristics. Future work integrating biologically relevant features, like autocorrelation or the log variance of milk yield, may further enhance predictive performance and support the development of decision support tools.

Impact of the use of Beef-on-Dairy on milk yield, calving traits and culling risk of the cow in subsequent lactation

L. Völker[1], C. Schmidtmann[2], L. Hüneke[2], G. Thaller[1]
[1] Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany, [2] IT-Solutions for Animal Productions (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany

The use of Beef-on-Dairy (BoD) has expanded markedly in recent years, driven by the enhanced economic value of crossbred calves and the widespread adoption of genotyping in dairy herds. Although the monetary advantage associated with BoD calves is widely recognized, little is known about the long-term consequences for the dam. This study aimed to evaluate the effects of different beef sire breeds on subsequent milk performance, calving traits, and functional longevity of Holstein Friesian cows that gave birth to BoD calves, in comparison with cows that had purebred calves. A total of 2,189,503 calving events from across Germany, recorded between 2015 and 2024, were analysed. Of these, 1,358,212 were in second parity and 831,291 in third parity. Beef sire breeds considered were Angus, Blonde d'Aquitaine, Charolais, INRA95, Limousin, Uckermärker and Belgian Blue. Traits analysed included milk, fat and protein yield in the subsequent lactation, as well as dystocia, stillbirth, and culling probability. Production traits were evaluated using mixed linear models, while calving traits and culling probability were analysed by logistic regression. The models accounted for fixed and random effects such as herd, calving year and season as well as the genetic potential of the dam. In second lactation, cows inseminated with beef sires exhibited significantly lower milk yield compared with cows that produced purebred calves, with the greatest reductions observed for INRA95 (-638 kg), Angus (-433 kg) and Belgian Blue (-222 kg). Similar patterns were found for fat and protein yield. In third lactation, the magnitude of these effects was even more pronounced. Dystocia had a substantial negative impact on milk yield (reduction of -218 kg in second and -205 kg in third lactation). Culling risk was increased for most beef breeds, particularly Charolais, Blonde d'Aquitaine, Uckermärker and Belgian Blue, with higher probabilities occurring in early and late stages of lactation. Cows that gave birth to BoD calves exhibited significantly higher odds of dystocia compared with cows that produced purebred Holstein-Friesian calves. The highest odds ratios were observed for Charolais (OR = 6.79), followed by Belgian Blue (OR = 4.54) and Uckermärker (OR = 3.91). The risk of stillbirth was significantly higher for cows that gave birth to Blonde d'Aquitaine (OR = 1.80), Charolais (OR = 1.64), Belgian Blue (OR = 1.52) and Uckermärker (OR = 1.39) calves. In contrast, cows that produced Angus, INRA95 or Limousin calves did not differ significantly in stillbirth probability from those giving birth to purebred Holstein calves. In conclusion, although the breeding strategy BoD enhances the economic value of calves, cows that give birth to crossbred calves of certain breeds are at greater risk for calving difficulties, exhibit an increased likelihood of culling, and show reduced milk production in subsequent lactations. These results highlight the importance of thoughtful and carefully planned sire selection to balance economic benefits with animal welfare, longevity and production efficiency in dairy systems.

Splitting the bill at the gate: Pricing system to reward management and genetic potential of Beef on Dairy calves

K. K. Johansen[1], B. H. Nielsen[1], R. D. Kring[1]
[1] SimHerd A/S, Niels Pedersens Alle 2, DK-8830 Tjele, Denmark

Calves enter the beef chain with very different starting conditions, reflecting variation in colostrum management, early nutrition, health status, genetics, and age at sale. These early-life factors are well known to influence health, mortality, growth rate, feed efficiency, slaughter weight, and carcass value. The Danish market has traditionally relied primarily on live weight, breed and sex premiums, providing limited incentive to optimize individual calf quality. This contribution discusses the rationale and implications of implementing a value-based pricing model on the Danish calf market. The tool, currently available for all Danish farmers via the Danish Dairy Management Software (DMS), predicts expected slaughter weight at 300 days using individual age and weight at transfer. It aims to reflect the calf's realized early growth as an indicator of future production potential. Genetic information of the dam and sire is included to reflect the genetic potential of the calf. Scientific evidence consistently demonstrates that early growth rate is strongly associated with lifetime productivity in cattle, supporting the use of age-adjusted growth indicators to predict future performance. Model development integrates scientific research and production data. Growth curves and expected feed intake were based on controlled trials of Beef on Dairy and purebred bull calves conducted at Aarhus University. These curves are scaled to fit production levels on all animals slaughtered in Denmark the past two years. Likewise the, calculating expected breed level of dressing percentage, EUROP score and mortality was extracted based on the same data. Financial records and abattoir pricing are used to estimate production costs and are regularly updated to reflect market conditions. The model predicts carcass weight with a root mean squared error (RMSE) of 24 kg and net growth with an RMSE of 155 g/day. While prediction error is non-negligible, it reflects variation observed in practice and compares actual carcass weight to expected carcass weight at day 300. As an illustration, the price difference between 24-day-old Beef on Dairy calves at the 25th and 75th percentile in weight is approximately 138 €. The model introduces a calf-specific base price and distributes the expected margin between dairy producer and finisher according to predicted performance levels. Stakeholder representatives have decided on a distribution model of expected revenue, making a fair price distribution, while creating incentive to increase early life growth of the calves. Market adjustment of the price enable alignment with supply–demand conditions without obscuring biological foundation for the model. The approach has implications for breeding strategies, use of sexed beef semen, colostrum management, and nutritional management during the neonatal period. By making the economic consequences of suboptimal early management more explicit, the model aims to strengthen incentives to improve calf robustness and uniformity. In practice this means that there can be up to 135 € difference in estimated value for calves of the same sex, breed combination and weight purely due to their age at the time of sale. The price difference is justified by a higher income potential of the calf. The topic concerns Beef on Dairy production systems and integrates principles from animal breeding, production economics, and herd management. Relevant stakeholders include dairy producers, calf finishers, breeding organizations and advisory services. Beyond economic efficiency, improved alignment of incentives across the value chain may contribute to improved animal welfare outcomes and societal acceptance of dairy-origin beef production.

HerdPlanner: Decision models for reproduction and culling decisions

E. Harms[1], R. Kool[1], M. Hagens[1], I. Adriaens[1], M. Sol[1]
[1] CRV, Rijksweg-West 2, 6842 BD Arnhem, Netherlands

Farm size is increasingly constrained by physical limitations (e.g., number of cubicles) and environmental regulations (e.g., nitrogen, phosphate, or CO_2 emission limits). To sustain profitability under these constraints, farmers must strategically balance youngstock numbers with the population of lactating cows. This is challenging because insemination decisions affect herd composition only after a delay of nearly three years, when resulting heifers enter their first lactation. HerdPlanner supports this decision-making process by guiding optimal insemination and culling strategies at the individual-cow and herd levels. Three workshops involving 29 farmers from across The Netherlands and Flanders were conducted to identify key challenges related to insemination choices, voluntary and forced culling, and long-term herd composition. We used their feedback to define a phased development roadmap for HerdPlanner. Phase one focuses on insemination advice. At the individual-cow level, decision models recommend to inseminate, wait, or not inseminate, using expected performance, lactation stage, projected dry-off yield, health status, and genetic merit. At the herd level, the models advise how many inseminations with sexed, conventional, or beef-on-dairy semen should be performed per 21-day cycle to achieve the desired number of replacement heifers for herd stability. These advisory functions are provided through an experimental module, "AI Lab", within CRV's farm management software. AI Lab enables rapid iteration based on user feedback regarding both content and presentation of model results. Phase two will expand the tool with culling recommendations informed by expected individual-cow economic performance. The advisory functions of Phase One are currently being evaluated through qualitative and quantitative feedback collected from approximately 50 farms over several months. In this presentation we will share and discuss the functionality and the insights we derived from the collected feedback. We will use that feedback to further improve HerdPlanner so that it provides farmers with actionable, model-based decision support to optimize herd composition within physical and environmental boundaries.

Fattening and slaughter performance of crossbred, German Holstein and Simmental bulls fed with sweet white lupine as protein source

A. Boldt[1], H. Sievers[1], I. Papstein[2], P. Sanftleben[1]
[1] Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries, Institute of Livestock Framing, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, [2] Agrargesellschaft Hohen Wangelin GmbH & Co KG, Malchower Chaussee 1, 17194 Hohen Wangelin, Germany

The practice of mating beef sires on German Holstein (HF) dams is increasing in several countries. Crossbreds from beef on dairy mating have a higher economic value because of heavier carcasses and lower proportions of trim than dairy bulls. Furthermore, interest in marketing regionally produced quality meat, made predominantly from locally produced feed, is increasing among both producers and food retailers. The various crossbreeds pose challenges, especially for fatteners, such as knowledge gaps concerning growth patterns as well as fattening and slaughter performance. Differences in nutrient and energy requirements of crossbreeds are currently given little consideration in ration calculations and feeding. Findings in this regard are of great importance for optimizing fattening and improving the economic efficiency of fattening farms. Therefore, the aim of this study is to investigate growth patterns as well as fattening and slaughter performance of regionally relevant crossbreedings. In addition, the suitability of sweet white lupine (SWL, lupinus albus) as a concentrated feed component in bull fattening will be tested. This will highlight an option for using a regional and sustainable protein feed in place of soybean meal. The trial included 150 bulls of HF (n=49), Simmental (FV, n=21), Angus x HF (ANGxHF, n=37), and Uckermärker x HF (UCKxHF, n=43). The 150 bulls were divided into two feeding groups. Both groups received an identical basic ration consisting of corn silage, grass silage, straw, pressed sugar beet pulp, wet corn, and mineral feed. In the control group (CG, n=79), protein supplementation was provided via soybean meal, whereas in the lupine group (LG, n=71), it was provided via SWL and soybean meal in the pre-fattening phase and only SWL in the final fattening phase. When optimizing the total rations, crude protein is equated. For each group, feed consumption and feed costs are recorded. The bulls are weighed five times during the trial period (after birth, day 28, day 90, day 185, day 325). In addition to the weighings on days 185 and 325, the longissimus dorsi muscle area and fat thickness of the animals are also measured using ultrasound. After birth calves weighed 42.6 kg (HF), 45.5 kg (ANGxHF) and 52.5 kg (UCKxHF). For the FV birth weight was not available. The trial started in February 2025 with an average age of 6.2 months and a weight of 247 kg. At that point highest back muscle area was shown by UCKxHF with 57.1 cm² and lowest by HF with 43.4 cm². The ANGxHF bulls had the highest fat thickness (3.13 mm) at start of trial, lowest UCKxHF (2.41 mm). In the pre-fattening phase the average daily weight gain (ADG) was higher in the LG (1,438 g/day) than in the CG (1,337 g/day). Furthermore, the LG showed a higher feed intake with 7.9 kg DM/d per animal than CG (7.6 kg DM/d). Highest ADG was observed in crossbred UCKxHF (1,469 g/day). The bulls were slaughtered in March 2026. To analyse differences between genotypes and feeding groups, parameters like carcass weight, slaughter yield, carcass conformation score, leg circumference, intramuscular fat and meat tenderness are recorded. More comprehensive results on slaughter performance and carcass quality will be presented and discussed at the conference. This study provides new insights on the suitability of SWL as a regional ration component for bull fattening. Moreover, internationally relevant and economically decisive recommendations can be given regarding the selection of suitable breeds or crossbreeds.

Post-weaning feed management of Holstein and beef × Holstein cattle: Effects on growth performance and carcass merit

E. E. Cornand[1,2], S. A. Terry[2], G. O. Ribeiro[1], M. D. Jelinski[3], Ó. López-Campos[4], G. B. Penner[1]
[1] University of Saskatchewan, Animal and Poultry Science, 51 Campus Drive, S7N 5A8 Saskatoon, Canada, [2] Agriculture and Agri-Food Canada, Lethbridge Research and Development Centre, 5403 1st Ave S, T1J 4B1 Lethbridge, Canada, [3] Western College of Veterinary Medicine, Large Animal Clinical Sciences, 52 Campus Drive, S7N 5B4 Saskatoon, Canada, [4] Agriculture and Agri-Food Canada, Lacombe Research and Development Centre, 6000 C and E Trail, T4L 1W1 Lacombe, Canada

Optimizing post-weaning nutritional strategies for beef × Holstein (B×H) cattle is critical to maximize growth efficiency and carcass value while minimizing health risk. We hypothesized that a moderate-energy growing program would improve retail cut yield and that B×H cattle would have improved growth and carcass traits over Holstein steers. The effects of dietary energy density during the growing phase on intake, growth performance, gain-to-feed ratio (G:F), and carcass merit of Holstein steers, B×H steers, and B×H heifers were evaluated. Weaned calves (n = 40/breed-sex; 205 ± 23 kg body weight, BW) were randomly assigned to either a rapid gain (RG; 1.9 kg/d) or moderate gain (MG; 1.2 kg/d) program during the growing phase (n = 20/breed-sex × program) and individually housed. The RG and MG grower diets contained 48% and 28% starch, respectively, and 15% crude protein (CP). When 70% of each breed-sex × program group reached 350 kg BW, cattle were transitioned to a common finishing diet (51.0% starch, 13.5% CP) and fed to market weight (steers, 756 ± 62 kg; heifers, 703 ± 41 kg). Intake was measured weekly and summed over 28 d periods to calculate gain-to-feed ratio, while BW and body measurements were obtained every 28 d. Continuous data were analyzed using PROC MIXED in SAS (Cary, NC, USA) with breed-sex, program, and the 2-way interaction as fixed effects, and barn wing as a random effect. Initial BW was a covariate for performance data, while final BW was a covariate for carcass data. Carcass quality grade (QG), yield class (YC), and liver abscess score (LAS) were analyzed using PROC GLIMMIX with a multinomial distribution and weighted count variable. No significant ($P > 0.05$) breed-sex × program interactions were detected. Dry matter intake did not differ by program, but was greater ($P < 0.01$) for B×H steers than Holstein steers and B×H heifers. Average daily gain (ADG) was greater ($P = 0.03$) for RG cattle than MG, and greatest ($P < 0.01$) for B×H steers. Gain-to-feed was unaffected by program, but was greatest ($P < 0.01$) for B×H steers and lowest for Holstein steers. Hot carcass weight (HCW) did not differ by program; however, B×H steers had greater ($P < 0.01$) HCW than Holstein steers and B×H heifers. Cattle fed RG had greater ($P < 0.01$) marbling score and backfat-thickness than MG cattle. Backfat-thickness differed among breed-sex ($P < 0.01$) with B×H heifers having the greatest and Holstein steers having least. Breed-sex and program did not influence ($P > 0.05$) QG or LAS, whereas YC differed by breed-sex and program ($P < 0.01$). The B×H steers were more likely (odds ratio, OR = 0.20; $P < 0.01$) to have higher carcass YC and tended toward lower odds (OR = 0.39; $P = 0.07$) of severe LAS than Holstein steers. The RG cattle had greater odds (OR = 7.55; $P < 0.01$) of poorer carcass YC than MG cattle. In summary, targeting RG during the growing phase improved ADG and marbling score without affecting gain-to-feed or liver health and did not interact with breed-sex. However, RG increased the likelihood of poorer carcass yield class, partially supporting our hypothesis and highlighting trade-offs between carcass quality and cutability in beef × dairy systems.

Effect of the inclusion of cocoa bean shells in the diet of fattening beef on live performance, carcass traits, and nutritional quality of the meat

A. Nudda[1], S. Carta[1], M. F. Lunesu[1], G. Battacone[1], S. P. G. Rassu[1], F. Correddu[1], G. Pulina[1]
[1] Università di Sassari, Dipartimento di Agraria, Viale Italia 39A, 07100 Sassari, Italy

Cocoa bean shells (CBS) represent a sustainable by-product for ruminant diets, but their long-term effects on local breeds remain underexplored. Aim of this study was to evaluate the impact of CBS inclusion on performance, blood parameters, carcass traits, and meat quality in Sardo Bruna cattle. Thirty Sardo Bruna cattle (15 females, 15 males) were divided into 3 groups (n = 10 per group) balanced by sex: control (CTR, basal diet), low-dose CBS (LD, +150 g/head/day), and high-dose CBS (HD, +300 g/head/day). The basal diet was offered ad libitum and was composed of a base of forage and concentrate mixed with a feed mixer offered twice daily. The forage component included straw and hay, while the concentrate included a commercial concentrate and corn meal. Over 6 months, monthly BW was recorded and average daily gain (ADG) was calculated. At slaughter, carcass weight and yield were measured; pH, temperature, and color (CIE Lab*) were assessed on Longissimus thoracis et lumborum (LTL) and Rectus abdominis muscles. LTL samples were analyzed for proximate composition; fatty acids profile and cooking and drip losses. Data were analyzed by ANOVA with diet, sex, and their interaction.Neither BW nor ADG differed by diet and males showed higher ADG than females ($P<0.05$). Carcass yield and cut weights were unaffected by CBS supplementation. In Rectus abdominis, HD increased b* parameter compared to CTR and LD $P<0.05$); females showed higher a* and b* in LTL muscle ($P<0.05$). Drip and cooking losses were unchanged by diet. Proximate composition was similar across diets, but HD increased PUFA n-3 in LTL muscle compared to CTR and LD ($P<0.05$). At the same time, sex influenced the FA profile: females had higher MUFA and males higher PUFA ($p<0.05$). Long-term CBS supplementation sustains live performance and carcass traits in Sardo-Bruna cattle while enhancing meat PUFA n-3 content. Overall, the study supports the safe use of CBS as a sustainable dietary supplement without compromising animal performance and meat quality. An integer programming approach to optimal selection and mating for herd improvement

I. Lagarde[1], E. Harms[1], M. Sol[1]
[1] CRV, Rijksweg-West 2, 6842 BD Arnhem, Netherlands

Sustained genetic progress in dairy herds requires transparent, data-driven guidance that supports both farmers and breeding advisors. We present an integrated framework that delivers optimized selection and mating recommendations by balancing genetic gain, inbreeding management, and farm-specific breeding objectives. The approach explicitly incorporates operational realities at the herd level, ensuring that genetic progress aligns with practical constraints. Methods The framework is built around a two-stage integer linear programming (ILP) procedure. Inputs include genomic breeding values, pedigree-derived inbreeding coefficients, recessive defect carrier status, trait-specific economic weights, and a comprehensive set of herd-level operational constraints. These constraints cover semen allocation rules, bull usage limits, prioritization of on-farm semen inventory, and parity-specific calving-ease conditions. For each potential mating, expected genetic merit, inbreeding, and defect-risk metrics are calculated. The first ILP identifies the mating plan that maximizes overall herd genetic gain while satisfying biological and management constraints. A subsequent optimization step enhances conformation consistency across the herd, providing coherent selection and mating guidance within a unified decision-support framework. The system was evaluated on 33 commercial dairy herds in the Netherlands, generating recommendations in parallel with conventional expert-driven breeding advice. Predicted genetic progress, compliance with farm constraints, and user feedback were compared between approaches. Farmers and advisors also completed a qualitative survey regarding clarity, perceived usefulness, and alignment with breeding goals. Results and conclusions Across all participating herds, the optimization framework delivered predicted genetic gains that matched or exceeded those from standard advisory procedures while fully respecting operational and biological constraints. Survey responses from both farmers and breeding specialists indicated strong overall acceptance, highlighting the clarity, practicality, and goal alignment of the recommendations. These results demonstrate that data-driven optimization can strengthen on-farm genetic decision-making and offer a scalable approach for future herd improvement tools.

Characterizing the complex genetic architecture of SINS reveals associations with physiological side effects of selection in swine

G. Reiner[1], K. Gerhards[1], M. Lechner[2], K. Koenders-Van Gog[3], S. Becker[1]
[1] Clinic for Swine/Justus-Liebig-University, Frankfurter Straße 112, 35392 Giessen, Germany, [2] UEG-Hohenlohe, Am Wasen 20, 91567 Herrieden, Germany, [3] Lintjeshof Farm health solutions, Pannenweg 200, 6031 RK Nederweert, Netherlands

Background and Objectives Swine Inflammation and Necrosis Syndrome (SINS) is a clinically defined endogenous syndrome in pigs, manifesting as lesions of tail, ears, teats, coronary bands, heels, and other body parts. It is widely distributed across countries and provides an animal-based measure to reduce tail lesions during fattening and at slaughter, a core welfare indicator. The aim of this presentation is to review the interactions between clinical, clinical-chemical, pathohistological, metabolomic, transcriptomic, and genomic data, and their implications for breeding and genetics. Genetic architecture of SINS While environmental factors such as feeding, management, and housing contribute, our data demonstrate that susceptibility to SINS is strongly genetically determined. Transcriptional profiling shows that clinical SINS is associated with upregulation of inflammatory and acute-phase genes and liver metabolic reprogramming, indicating a systemic rather than localized response. Genomic analyses reveal that key mediators of these pathways are heritable and distributed across multiple quantitative trait loci, establishing a polygenic architecture underlying individual susceptibility. SINS correlates with physiological traits commonly observed as side effects of intensive selection for performance, including metabolic stress, immune dysregulation, and reduced resilience. Modern breeding increasingly includes tail integrity as a performance trait, economically incentivized in production. Because SINS predisposition directly affects tail health, selection for intact tails intersects with genetic susceptibility to SINS, highlighting a practical limitation and the tension between production goals and animal welfare. Application in breeding programs These findings illustrate that expression of genetic potential in high-performance pigs can produce unintended consequences for health and welfare. SINS serves as a model where clinical manifestation, genetic architecture, and physiological correlates converge, emphasizing opportunities and constraints in modern swine breeding. Integrating clinical, transcriptomic, and genomic evidence shows that SINS should be considered both a heritable syndrome and a phenotypic indicator of physiological stress, rather than solely an environmental problem. These insights inform multi-trait selection strategies that balance growth, feed efficiency, reproductive performance, tail integrity, and resilience, providing a framework to manage correlated physiological risks in production.

Genetics of swine inflammation and necrosis syndrome: What do we know so far?

N. G. Leite[2], A. O. Garcia[1], R. Vogelzang[2], L. Vargovic[2], S. Nuphaus[2], Ø. Nordbø[2], M. Londoño-Gil[2], J. Dunkelberger[2], E. Grindflek[2]

[1] University of Georgia, Animal and Dairy Science, 425 River Rd, 30602 Athens, United States, [2] Topigs Norsvin, Research Center, Meerendonkweg 25, 5216 TZ 's-Hertogenbosch, Netherlands

Skin lesions in pigs are commonly attributed to damaging behaviors such as tail and ear biting and represent major welfare and economic concerns in swine production. However, lesions observed at birth or shortly thereafter suggest that some injuries may originate from Swine Inflammation and Necrosis Syndrome (SINS), a condition characterized by inflammatory and necrotic alterations in the extremities, including ears, tails, teats, and claws, which can be observed at birth, before animal interaction, or other factors such as flooring or tail docking. Across studies conducted within Topigs Norsvin, involving different pig lines and breeds, results indicate that SINS has a genetic component, with low-to-moderate heritability estimates (0.03–0.34). Both direct genetic effects and smaller maternal effects contributed to variation in the syndrome. A consistent finding across these studies is a genetic association between early-life SINS, observed in piglets up to 3 days of age, and skin damage observed in finishers, with genetic correlations ranging from 0.19 to 0.78. Wide ranges in heritability and genetic correlation are due to variation among breeds, lines, trait definitions, and body regions evaluated. The genetic relationship between SINS and skin damage in finishers suggests two possibilities: (1) pigs more prone to inflammatory lesions early in life may also be more susceptible to injuries often attributed to damaging social behaviors, and (2) skin damage observed in the finishing stages, commonly associated with abnormal behaviors such as ear and tail biting, may be partially confounded with SINS. In either case, selection against SINS could indirectly reduce the prevalence of skin damage in finishers. Beyond the relationship between SINS and skin damage, SINS was also genetically correlated with production traits such as birth and weaning weight (-0.40 to -0.30), whereas it showed only minor relationships with carcass traits such as loin depth and backfat (-0.16 to 0.05). Although these findings highlight the genetic relevance of SINS and its potential role as an early indicator of welfare outcomes, its relationships with other production and reproduction traits remain to be further explored. Therefore, this study aims to investigate the genetic relationships among SINS, reproductive traits, and cardiorespiratory traits assessed via CT scanning in a purebred dam line. The SINS dataset includes binary information on lesions of teats, ears, and tails, recorded within the first three days of life for 6,229 piglets born between 2022 and 2025 across one Canadian and two Dutch farms. For a subset of these animals and their relatives across up to three generations, reproductive performance (N = 14,717) and CT-derived cardiorespiratory traits (N = 13,069) were available. Reproductive traits included total number born, number of stillborn, gestation length, and litter mortality, while CT scan traits captured heart and lung weights. We hypothesized that SINS would exhibit weakly unfavorable genetic correlations with reproductive traits and a moderately unfavorable correlation with cardiovascular capacity, supporting previously reported links between SINS and blood flow and circulatory disturbances.

Ear necrosis: Evidence of pigs reaching their biological limits?

L. Markland[1,2], F. Leonard[2], K. O'Driscoll[1], L. Boyle[1]
[1] Teagasc, Pig and Poultry Department, Moorepark, P61C969 Fermoy, Ireland, [2] University College Dublin, School of Veterinary Medicine, Belfield, D04W6F6 Dublin, Ireland

Ear necrosis has emerged as a major welfare problem arising from the intensification of pig production. It is a prevalent but poorly understood, multifactorial disease affecting young pigs in intensive systems worldwide, and there are currently no successful mitigation strategies. Through a series of experimental and observational studies across 4 years, we examined the prevalence and progression of ear necrosis, and relationships between ear necrosis and several factors including early life experiences, management practices, damaging and aggressive behaviours, and physiological biomarkers. The research confirmed that ear necrosis development cannot be attributed to any single factor. Controlled trials were conducted to investigate the influence of pre- and post-weaning supplementary nutrition strategies and pre- and post-weaning improved hygiene protocols on post-weaning ear necrosis development. Despite some positive effects on pig growth and feed intake, there was no effect on ear necrosis ($P > 0.05$), indicating that single-variable interventions are unlikely to successfully ameliorate the disease. Additionally, we found the first conclusive evidence that ear biting behaviour performed by piglets ($N = 298$) during the pre-weaning period has a critical influence on the future risk of ear necrosis: an increase in the frequency of ear bites received at week 3 of age increased the risk of developing ear necrosis post-weaning ($OR = 3.34$; $P < 0.05$). Histopathological examination of ears from 32-day old piglets revealed that pre-weaning ear biting behaviour causes measurable tissue damage, supporting the hypothesis that repetitive oral manipulation compromises tissue integrity and increases the risk of ear necrosis. An investigation of physiological biomarkers in oral fluid demonstrated that ear necrosis is associated with elevated markers of inflammation and immune activation. A trial conducted on a commercial grower-finisher farm ($N = 48$ pens; 1,676 pigs) revealed a high prevalence of ear necrosis and negative behaviours (ear, tail, and flank biting, and aggression), and considerable pen-level variation, suggesting the presence of pen and individual-level risk factors. A study of 21 commercial Irish farms confirmed the widespread nature of ear necrosis: ear necrosis was found on 100% of the farms and an average of 30% of pigs were affected per farm, which is an increase from the reported prevalence 7 years prior. Ear biting behaviour was performed at high levels throughout the production stages across all studies. Together, this research contributes novel evidence regarding ear necrosis aetiology, emphasizing the complex, context-dependent nature of risk factors, where ear biting behaviour plays a key role. The research suggests that ear necrosis is a production disease, i.e. the undesirable outcome of increasing production pressures rendering pigs unable to cope. In conclusion, this underscores the difficulties of addressing the disease within the constraints of the current production system.

Pathological investigation of cardiovascular disease in broilers

I. Thøfner[1], T. A. S. Al-Saeedi[1,2], S. S. Nielsen[3], S. Kabell[4], J. P. Christensen[1]
[1] University of Copenhagen, Dep. of Veterinary and Animal Sciences, Stigbøjlen 4, 1870 Frederiksberg C, Denmark, [2] University of AL- Qadisiya, Dep. of Animal Production, College of Agriculture, 58002 AL-Diwaniyah, Iraq, [3] University of Copenhagen, Dep. of Veterinary and Animal Sciences, Grønnegårdsvej 8, 1870 Frederiksberg C, Denmark, [4] Rose Poultry part of Plukon, Tværmosevej 10, 7830 Vinderup, Denmark

This abstract addresses cardiovascular disorders in broilers, presented as a case example for the session's structured discussion. Cardiovascular problems, often associated with rapid growth, remain the most common cause of mortality in broilers under non-outbreak conditions and are a major reason for carcass rejection at slaughter. Evidence suggests a genetic contribution, and pathology indicates two forms: an acute form characterised by generalised circulatory disturbances, oedema and congestion, and a chronic form involving cardiac dilatation, liver cirrhosis and ascites. This study included Ross 308 broilers at 33 and 41 kg/m² (slaughtered at 34 days) and Rustic Gold broilers at 36 kg/m² (slaughtered at 41 days) and used a repeated cross-sectional design (3 rotations/group) across 33 flocks on eight Danish farms (2023–2024). From day-old to slaughter, dead, euthanised or rejected birds were collected and necropsied. Of 6839 birds, 3503 birds (51%) were classified with cardiovascular collapse, each showing ≥3 characteristic lesions. First-week mortality, cumulative mortality, dead on arrival (DOA) and carcass rejection rates were within normal range in all flocks and did not differ significantly between broiler groups. During the first week, cardiovascular collapse accounted for 28.7% of deaths, with no significant differences between broiler groups. Ventricular dilatation occurred in 8.7% of 1-day-old chicks but was rarely accompanied by other cardiovascular lesions, suggesting genetic or hatchery-related factors. From day 8 to slaughter, cardiovascular collapse was the dominant cause of on-farm mortality (81%). Overall cardiovascular collapse rates did not differ significantly between broiler groups, but both Ross 308 broiler groups had significantly higher rates of cardiac dilatation and ascites than Rustic Gold. Birds >28 days were more likely than younger birds to exhibit chronic lesions such as ascites and liver cirrhosis. Distinct lesion patterns allowed differentiation between chronic heart failure and Sudden Death Syndrome (SDS), the latter characterised by acute circulatory disturbances and lung oedema. Among DOA birds, 75% were classified with cardiovascular collapse, with significantly fewer birds involving cardiac dilatation in Rustic Gold. Low body weight (<1750 g) was associated with higher rates of ascites, cardiac dilatation and liver cirrhosis in both DOA and rejected birds, indicating prolonged survival of chronic cases. Neither the use of Rustic Gold birds nor lowering stocking density reduced cardiovascular-related DOA outcomes. Ascites, the third most common cause of carcass rejection (17.2%), occurred more frequently in Ross 308 birds than in Rustic Gold. The probability of chronic cardiovascular lesions was doubled in carcasses <1.750 g. Overall, cardiovascular disorders accounted for 51% of deaths and rejections across all stages despite normal flock mortality rates. Genetics, management and environment have previously been shown to influence susceptibility on both chronic heart failure and SDS. Findings highlight a substantial welfare burden and emphasise the need for integrated breeding and management strategies that balance welfare improvements with economically sustainable production. This raises the question: what is an acceptable level of cardiovascular disease in broiler production?

From behavior to immunity: Sex-related differences in immune cell composition in chicken lines selected for high and low feather pecking

T. Hofmann[1], W. Bessei[1], V. Stefanski[1], S. Schmucker[1]
[1] Institute of Animal Science, Garbenstr. 17, 70599 Stuttgart, Germany

Feather pecking is a serious behavioural disorder in chickens, leading to feather loss, skin injuries, increased stress, and higher mortality rates. Despite extensive research, the underlying mechanisms are not fully understood. Feather pecking is considered a multifactorial trait influenced by genetic, environmental and physiological factors, including the immune system. It has a higher incidence in hens compared to roosters. Studies in humans and mice have demonstrated that psychiatric disorders and related personality traits, such as impulsiveness and hyperactivity, are associated with alterations in the immune system, particularly in T-cell composition and inflammatory processes. Given common features between FP in chickens and humans with psychiatric disorders, feather pecking may likewise be associated with alterations in T cell immunity. The aim of this study was to investigate the immune system of hens and roosters of a high (HFP) and low feather pecking (LFP) line to identify differences between genetic predisposition and sex. Lines had been divergently selected based on the severe feather pecking behaviour of hens, resulting in a HFP and a LFP line. A total of 120 hens (60 HFP, 60 LFP) and 60 roosters (30 HFP, 30 LFP) from the 20th generation of selection were examined. At 42 to 43 wk of age, birds were slaughtered, and blood, spleen and caecal tonsils were sampled. Immune cell populations were characterized using flow cytometric analysis using a no-lyse-no-wash method and staining with chicken-specific fluorochrome-conjugated antibodies. Statistical analyses were performed using a linear mixed model (SAS 9.4). Immunological differences were observed both between sexes and between selection lines, with several effects being also tissue-specific. Overall, roosters had higher numbers of several immune cell types in spleen and caecal tonsils compared to hens. In the spleen, higher cell numbers in roosters were mainly attributable to their larger organ mass, whereas in the caecal tonsils they primarily reflected higher cell density. In spleen and blood, HFP chickens had generally lower immune cell numbers than LFP chickens, indicating genetic differences in immune cell availability or mobilization. Line effects in the caecal tonsils were predominantly sex-dependent, particularly affecting $CD4^+$ cells and their subsets. Notably, $CD4^+$ cell numbers were exclusively lower in HFP hens. These data demonstrate an association between immunity and feather pecking and suggest that divergent selection for feather pecking influenced immune cell profiles. Given that feather pecking is predominantly expressed in females, the selective reduction of $CD4^+$ cells in the caecal tonsils in HFP hens supports the hypothesis that feather pecking might be an immune-associated behaviour, potentially linked to immune dysregulation in the gut.

Investigating differential gene expression in the pectoral muscles of broiler chickens affected by wooden breast condition

M. Bordini[1], S. Gioiosa[2], M. Petracci[1], F. Soglia[1]
[1] Alma Mater Studiorum University of Bologna, Department of Agricultural and Food Sciences, Piazza Goidanich 60, 47521 Cesena, Italy, [2] CINECA, HPC Department – Consorzio Interuniversitario, Piazza dell'Indipendenza 11B, 00185 Rome, Italy

Nowadays, poultry represents the primary driver in global meat production. This has been possible due to the remarkable advancements in poultry selection, nutrition, housing, and meat processing. As a downside, the outstanding progress in this field also determined the occurrence of challenges. Among these, the manifestation of meat quality defects, commonly referred to as "growth-related myopathies", particularly affecting the Pectoralis major muscles (PMs) of the modern fast-growing broilers, remains a major area of research. Within this context, the present study was developed within the PRIN 2022 PACHOL4 project, which aims to investigate the molecular basis of wooden breast (WB), a major quality defect in broilers, with a specific focus on characterizing the transcriptomic profile of WB-affected breast muscles. Given the importance of accurately classifying PMs to properly investigate factors associated with the onset of these abnormalities and to avoid misleading results, a total of 180 breast fillets were collected at a commercial processing plant and classified as WB-affected or normal (N) based on their macroscopic appearance. After validating their macroscopic classification through multivariate analysis of meat quality data, 10 samples/group (WB and N) were selected and used for transcriptomic analysis. Briefly, total RNA extracted from each sample was checked for quality and used for RNA-seq using NovaSeq X-Plus technology. Raw-reads quality check, trimming, alignment to the reference genome, and count were performed on the High-Performance Computing platform provided by ELIXIR-IIB HPC@CINECA. After raw-reads processing, differential analysis was performed in R using DESeq2 and limma packages, while functional categories significantly enriched by the DEGs were detected by using DAVID Knowledgebase v2024q4 and considering a Benjamini–Hochberg adjusted p-value of 0.05 as significance threshold. Considering a log2fold-change>|1| and a q value<0.05, a total of 565 differentially expressed genes (DEGs) were found. Among those, 483 and 82 were respectively up- and down-regulated in WB compared to N. In accordance with the literature, functional analysis of up-regulated DEGs evidenced genes involved in PI3K-Akt and cytokine-mediated signaling pathways (P<0.001), as well as cellular components related to collagen trimer composition and ECM-receptor interaction (P<0.001), while functional terms related to carbon metabolism, glycolysis, and biosynthesis of amino acids were found enriched by the down-regulated DEGs (P<0.0001). Notably, MYBPC3, TNNT2, and ACTC1, which are involved in the dilated and hypertrophic cardiomyopathies in humans and are generally transiently expressed in embryonic chick skeletal muscles, were found among the up-regulated DEGs in WB (P<0.05). Therefore, the present results not only corroborate part of the existing literature but also highlight the dysregulation of several genes involved in cardiac-related pathways in PMs affected by WB. Even though a direct association with cardiac hypertrophy in WB-affected birds cannot be speculated, similarities in the underlying biological and molecular mechanisms between these two conditions, as well as the occurrence of gene expression patterns resembling the early stage of muscle development in WB muscles, have been hypothesized. This research was supported by NextGenerationEU, National Grant PRIN2022 (Prot. n. 2022EPWEPW).

Mapping production independent mastitis risk in German Holsteins using GWAS SEM

L. A. Gutekunst[1], V. P. Haas[1], C. Schmidtmann[2], J. Tetens[3], G. Thaller[4], J. Bennewitz[1]
[1] University of Hohenheim, Institute of Animal Science, Garbenstrasse 17, 70599 Stuttgart, Germany, [2] IT Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden, Germany, [3] Georg August Universität, Functional Breeding, Burckhardtweg 2, 37077 Göttingen, Germany, [4] Christian-Albrechts-Universität, Institute for Animal Breeding and Husbandry, Olshausenstraße 40, 24098 Kiel, Germany

Mastitis is among the most costly diseases in dairy cattle worldwide. Its antagonistic genetic correlation with milk production traits poses challenges for reducing mastitis risk in high-producing animals without compromising production performance. Thus, we aimed to separate mastitis specific genetic signals from those shared with milk yield using structural equation modeling (SEM) and to integrate gene expression data to identify possible causal genes underlying mastitis risk independent from milk yield. The relationship between the single nucleotide polymorphisms (SNPs; n = 16,882,734) and the traits milk yield and mastitis was captured by a Cholesky model. Two mediating latent factors were defined that exclusively impacted mastitis phenotypes or affected both milk yield and mastitis. Regression weights of the latent factors on the observed traits were determined using heritabilities and genetic correlations of milk yield and mastitis estimated in 34,497 German Holstein cows. Based on GWAS summary statistics for milk yield and mastitis, SNP effects on the latent factors were then estimated to identify loci associated with production-independent mastitis susceptibility. A two-sided Z-test was performed to identify genome-wide ($p < 2.96*10^{-9}$) and suggestively significant SNPs ($p < 5*10^{-6}$). Finally, we intersected publicly available gene expression data on single-cell level (8,866 bulk RNA-seq samples plus 999,192 single cells) with those loci. We found that 91 % of the genetic variance in mastitis was production independent. Although no SNPs passed Bonferroni-correction ($p < 2.96*10^{-9}$), 922 SNPs were suggestively significant for production-independent mastitis risk ($p < 5*10^{-6}$). Of these, 77 % of hits were located within the GC-NPFFR2 region on BTA6. The lead SNP was located on BTA10, closest to SEMA6D located 251 kb downstream. The strongest candidate gene based on the integration of expression QTL (eQTL) data was GRIP1 (BTA5) occurring in several layers of the single-cell resolution eQTL data and displaying consistent effect directions within layers. Our findings are consistent with known candidate genes for mastitis resistance in dairy cattle. The identified genes are involved in cytokine signaling, macrophage activation, and inflammation, and are plausible in the context of mastitis resistance. Collectively, this study shows that SEM combined with the integration of gene expression data is a promising tool for disentangling the interrelationships of antagonistically correlated quantitative traits. The identified candidate genes could help to design future breeding schemes for healthy and high producing animals.

From genetic potential to robustness: insights from energy-allocation models

F. Douhard[1], J. Raoul[1,2]
[1] INRAE, Animal Genetics, GenPhySE, Université de Toulouse, INRAE, ENVT, F-31326, 31321 Castanet-Tolosan, France, [2] Idele, Chemin de Borde Rouge BP 52627, 31321 Castanet-Tolosan, France

The mismatch between animal genetics and production environments is a long-standing concern that may become increasingly prominent under future farming conditions. Classical quantitative-genetic analyses often reveal limited genotype-by-environment interactions (G × E), yet physiological evidence suggests that biological trade-offs can affect relationships between traits when animals face nutrient scarcity or high metabolic demands. Such constraints on resource allocation are thought to play a central role in animal robustness. Within this framework, energy-allocation models integrating quantitative genetics have been proposed to explore how G × E may emerge from underlying physiological processes. Based on published modelling studies and on our own work with a dynamic sheep model, we discuss the potential benefits and limitations of this approach. A key assumption is that input coefficients controlling energy allocation among maintenance, growth, reproduction, and body reserves are genetically variable and less sensitive to environmental variation than model outputs representing observable performance traits. Although this assumption remains untested, it is key for simulating animal responses across diverse conditions. Simulation experiments show that genetic variation in specific allocation coefficients can generate substantial differences in lifetime trajectories and help identify robust animals. We also show that the assumed genetic variances and covariance structure among input coefficients strongly influence the genetic parameters of output traits and must therefore be chosen carefully. Finally, combining mechanistic modelling with a breeding-scheme simulation highlights differences between predicted selection responses and those obtained with classical quantitative genetics. Overall, we provide a balanced perspective on the use of mechanistic models in a genetic context: their complexity allows to reveal key biological insights into G × E but it also poses strong challenges for empirical validation.

From genotype to phenotype: expectations and limitations

K. Huber[1]
[1] *University of Hohenheim, Institute of Animal Science, Fruwirthstrasse 35, 70599 Stuttgart, Germany*

Once the oocyte and sperm are united forming the embryo, genetic potential drives the development of the new organism. However, during embryonal and fetal genesis in utero or in ovo, maternal or environmental challenges modulate the genetic potential by epigenetic modifications with consequences for later life. After birth or hatch, a second plastic window during early life allows further long-lasting epigenetic modifications. After weaning or hatch, high performing farm animals are fed according to their genetically determined growth potential and high feed intake capacity. Thus, production of meat is highly effective and cost-efficient. However, rapid growth can lead to immature tissues and organs and may thus not be efficient. By intensive postweaning feeding, female farm animals are pushed to reach their sexual maturity as early as possible. Immaturity of tissues and organs in females could cause a weaker fertility and shorter productive lifespans. The genetic selection for specific metabolic performances such as milk and eggs promotes extensive growth and development of target organs which leads to disproportionality between anatomical and functional features within the individual. Selective breeding for performance has set an imbalance within the orchestrated interplay of all organs and tissues. Because of immaturity and disproportionality, animals develop a high risk to suffer from production diseases and reduced resilience. Therefore, it is often observed that the phenotype predicted by the genotype is not matching the phenotype in production reality due to epigenetic modulations, rearing and feeding regimens and management decisions. The presentation will show an overview about current knowledge of physiological processes and their plasticity in ontogenesis of individuals which may help to explain the mismatch between genotype and phenotype. Respective examples in different farm animal species will be presented in detail in the talk.

Balanced breeding goals: genetics as part of the solution to livestock welfare and sustainability challenges

C. Baes[1], A. Harlander[1], S. Barbut[3], B. Wood[2], F. Miglior[1,4]
[1] University of Guelph, Department of Animal Biosciences, 50 Stone Rd, N1G2W1 Guelph, Canada, [2] University of Queensland, School of Veterinary Science, Gatton Campus, QLD 4343 Gatton, Australia, [3] University of Guelph, Department of Food Science, 50 Stone Rd, N1G2W1 Guelph, Canada, [4] Lactanet, Breeding and Genetics, 660 Speedvale Avenue West, N1K 1E5 Guelph, Canada

Selective livestock breeding has delivered remarkable gains in productivity over the past decades, enabling the efficient production of high-quality animal protein for a growing global population. As the demand for animal-source foods increases, livestock systems must simultaneously improve productivity, reduce environmental impacts, and maintain high standards of animal health and welfare. This challenge has intensified the debate about whether modern breeding has pushed animals beyond their biological limits. These concerns are legitimate. For example, high-performing dairy cattle populations have faced challenges related to metabolic stress, fertility, and longevity, while in poultry, skeletal disorders and breast muscle myopathies raise similar questions about the biological consequences of rapid genetic progress. Such observations highlight the need to continually reassess breeding goals as biological insights, production environments, and societal expectations evolve. Over the past two decades, livestock breeding has fundamentally shifted towards multi-trait selection frameworks that integrate productivity with health, welfare, robustness and functional longevity. Where early breeding programs prioritized yield and risked unfavourable correlated responses in functional traits, contemporary breeding programs increasingly incorporate health, fertility, longevity, efficiency, and resilience directly into multi-trait selection indices. Evidence across species show these balanced breeding goals enable simultaneous genetic progress in productivity and functional traits, demonstrating that genetic improvement can actively contribute to healthier and more robust animals. Advances in quantitative genetics and genomics have enabled this shift. Large-scale phenotyping and genomic evaluations now allow complex welfare-related traits to be measured and improved through selection. In dairy cattle, genetic studies have demonstrated heritable variation for mastitis resistance, fertility, longevity, metabolic stability, and resilience to environmental stressors such as heat stress. In poultry, research has identified genetic components underlying leg health disorders and muscle myopathies, providing the basis for breeding strategies that reduce their incidence while maintaining production efficiency. Genomic tools have also transformed the management of rare but severe genetic defects. Routine genomic screening enables the identification of carriers of deleterious variants, allowing breeders to avoid high-risk matings and substantially reduce the prevalence of harmful alleles without compromising genetic progress. Importantly, genetic improvement is increasingly aligned with broader sustainability goals. Selection now addresses feed efficiency, methane emissions, resilience to climatic stressors, and overall robustness, features that help animals maintain health and performance across variable environments and production systems. Feeding a growing global population while reducing the environmental footprint of agriculture requires animals that are productive, healthy, resilient, and efficient. Genetic improvement alone will not solve the complex challenges facing livestock systems, but, when integrated with advances in nutrition, management, and veterinary care, it remains one of the most powerful and durable levers for improving the welfare, sustainability, and productivity of farm animals.

Why laying hens struggle with vertical space: biomechanical constraints and implications for aviary design

A. Harlander[1], B. Tobalske[2], R. Garant[1], J. Page[1], N. Van Staaveren[1]
[1] University of Guelph, Animal Biosciences, Campbell Center for the Study of Animal Welfare, 50 Stone Rd E, N1G2W1 Guelph, Canada, [2] University of Montana, Division of Biological Sciences, 32 Campus Drive, 59812 Missoula, United States

Aviaries are designed to promote freedom of movement, yet laying hens face substantial biomechanical challenges when navigating vertical space. Modern hens are ground-dwelling, high-wing-loading birds whose flight consists of short, explosive bursts rather than controlled aerial manoeuvring. When key resources are located on upper tiers, hens must rely on descent by flapping or gliding, but their capacity to adjust trajectory, decelerate, or modulate lift appears limited. Understanding these constraints is essential for designing housing systems that align with the physical abilities of today's strains to avoid injuries. To examine these limitations, we synthesized findings from three biomechanical studies (Leon et al., 2021; van Staaveren et al., 2023; Hong et al., 2024) involving hens of different ages (34–70 weeks), strains, health conditions, and training histories. Across studies, we quantified flight kinematics and ground reaction forces during descent and landing. In the first study, feather clipping reduced wing area in 34-week-old Lohmann LSL Lite hens (n=18) to challenge aerodynamic capacity. Hens descending from 1.5 m with ~50% wing area exhibited rapid vertical velocity (3.9 m/s) and high horizontal acceleration, without compensatory changes in wingbeat frequency, amplitude, or angular velocity, indicating that hens operate near their muscle power limits and cannot adjust wing control when lift is compromised. A second study examined the influence of painful conditions—foot pad dermatitis (FPD) and keel bone fracture (KBF)—on landing mechanics in 70-week-old hens (n=37). Landing velocity and impact force increased with height (3.3× body weight at 30 cm; ~6.6–7.1× BW at 170 cm). Hens with KBF showed higher descent velocities (+17–21%) and tended to experience higher peak landing forces (+24%) than those with FPD. Meloxicam did not reduce landing loads and, in hens with FPD, tended to increase velocity and impact (~+16% BW at 170 cm). A third study evaluated whether 16 weeks of wing-assisted incline running (WAIR) training improved flight performance. In 37-week-old hens (n=82), WAIR modestly increased initial flight velocity (+6.5%) and tended to reduce descent acceleration, but descent velocity and trajectory angle (33–37°) remained unaffected. Collectively, these studies demonstrate that laying hens possess limited biomechanical capacity to modulate descent, require substantial landing distances, and experience high impact forces—constraints intensified by feather loss, injury, or reduced lift. As aviaries are complex, these physical limits highlight an urgent need for housing systems that match the abilities of modern laying hens, rather than assuming birds can adapt to environments that exceed their biomechanical thresholds.

When genetic potential meets production reality: implications for the animal. Discussion and summary of the session

K. Huber[1], H. Sauerwein[2], L. Boyle[3], C. Baes[4]
[1] University of Hohenheim, Institute of Animal Science, Fruwirthstrasse 35, 70593 STuttgart, Germany, [2] University of Bonn, Institute of Animal Science, Katzenburgweg 7, 53115 Bonn, Germany, [3] Teagasc, Ddepartement of Pig Development, Fermoy Co. Cork, P61C007 Moorepark, Ireland, [4] University of Guelph, Ontario Agricultural College, 50 Stone Road East, N1G 2W1 Guelph, Canada

This seminar should summarize implications for the animal regarding its genetic potential, its resulting phenotype in production reality and associated changes in behavior. The final phenotype of a farm animal is based on genotype but also on many other influencing factors such as management and feeding which could lead to changed behaviors. Many questions arise from this interrelationship which will be discussed in this session´s seminar: Could we improve genotype-phenotype relationships and thereby, animal health and welfare despite high performance? What do we need to know about modern farm animal physiology? Are specific behavioral patterns signaling animal welfare? Can anatomical, physiological and behavioral features be used to adjust breeding goals? What management and feeding regimen should be adapted to the needs of high-performing farm animals? The time span created by this abstract will be used to summarize and discuss the findings of session 3.

Rumen-protected B vitamins improved growth potential of female dairy calves after weaning

R. Roszkos[1], U. Blaeser[2], D. Bouchut[3]
[1] Jefo Europe SA, 2 Rue Claude Chappe, 44470 Carquefou, France, [2] Jefo Europe SA, 2 Rue Claude Chappe, 44470 Carquefou, France, [3] Jefo Europe SA, 2 Rue Claude Chappe, 44470 Carquefou, France

Title: Rumen-protected B vitamins improved growth potential of female dairy calves after weaning Authors:Robert Roszkos, Ursula Blaeser, Dominique Bouchut Abstract: The objective of this study was to evaluate the effects of feeding a blend of rumen-protected B vitamins (RPBV; thiamine, folic acid, biotin, pyridoxine, and pantothenic acid) compared to negative control on the growth potential and performance parameters of weaned dairy heifers. After weaning, calves were allocated into 8 consecutive batches of 16-24 calves in each and received either (experimental) or no RPBV (control) supplementation in alternating manner. All calves were fed a liquid diet until weaning and were gradually introduced to a calf starter and a dry TMR starting at 10 days of age. RPBV (3 g/calf/day) was included to the calf starter from the first day of the trial. This starter feeding phase continued for 2–3 weeks post-weaning, after which corn silage was incorporated into the TMR and remained in the ration until the end of the trial (approximately 3 months per batch). The trial lasted ~80 days. Body weights (BW) were recorded at the beginning and at the end of the trial, as well as data of culled animals. Calves within each batch were born within 2 weeks and the overall calf age at the beginning of the trial was 87.5 days (STD = 6.9 days). Initial BW varied similarly to initial calf age (115.5 kg, STD = 5.4kg). Average daily gain (ADG) was calculated individually by dividing total BW gain by the total number of feeding days. Data were analyzed using ANCOVA procedure (XLSTAT software, v2024.4) using batch (1, 2, 3, 4) as a fixed effect. Initial BWs and age were used as a covariate in the analysis of ADG. Calves receiving RPBV gained 56 ± 34.7 g/d more than control during the feeding period (ADG: 1,043 vs. 1,099 g/day; P = 0.01). The ADG of calves of the RPBV group was higher in every single batches. Within the control, 2 calves were culled (reasons were: bloat, coccidiosis) and 3 others gained less than 700 grams per day during feeding. No calves were culled in the RPBV group and ADG was over 700 grams for all animals. In conclusion, the addition of RPBV to diet of growing dairy female calves can improve their performance and health status during the stressful post-weaning period.

Genetic Variant Mapping Across Multi-Tissue Transcriptomes Reveals Genome-wide Regulatory Signatures in Bovine IVP and MOET Calves

U. Gk[1], P. P. Pathade[1], J. Bojsen-Møller Secher[3], H. Kadarmideen[1,2]
[1] Aarhus University, Aarhus University, Blichers Alle, 20, 8830 Tjele, Denmark, [2] Aarhus University, Molecular Biology and Genetics, 81,Universitetsbyen, 8000 Aarhus C 81,Universitetsbyen, 8000 Aarhus C, Denmark, [3] University of Copenhagen, Veterinary Clinical Sciences, Højbakkegaard Alle 5A, 2630 Taastrup, Denmark

In cattle breeding programs, in vitro production (IVP) and multiple ovulation and embryo transfer (MOET) are widely applied, however these reproductive strategies relate to transcriptome-wide gene expression patterns, and the landscape of expressed genetic variants has not been systematically characterized. Understanding the genome-wide genetic regulation of gene expression across different tissues is essential for deciphering the genetic architecture of complex reproductive traits. Although calves derived from these systems differ in developmental competence, metabolic adaptation, and reproductive performance, genotype–expression relationships across key endocrine and metabolic organs have not been systematically characterized. Therefore, the main objective of this study was to investigate the genetic control of gene expression in Hypothalamic–Pituitary–Adrenal–Gonadal (HPAG) organs central to bovine reproduction and fertility. We hypothesized that IVP and MOET calves exhibit distinct coding and regulatory variant profiles across major reproductive tissues and that functional SNPs may partially explain transcriptional differences. To address this, we performed multi-tissue RNA-seq of Adrenal, Hypothalamus, Liver, Muscle, Pituitary, and Testicle from eight calves (IVP n=4; MOET n=4), generating 48 transcriptome libraries. Variants were called using GATK, identifying ~300,000 SNPs per sample per tissue. Stringent multi-parameter filtration removed low-quality and strand-biased variants, producing a high-confidence transcriptome-derived SNP dataset. Functional annotation with ANNOVAR classified variants into synonymous, nonsynonymous, splice-site, UTR, intronic, and regulatory categories, with nonsynonymous and splice-site variants prioritized as potential coding-impact changes. Cross-tissue analyses revealed conserved polymorphisms alongside organ-specific variation. Comparison of IVP and MOET groups identified shared and group-specific SNPs, indicating both common genetic architecture and reproductive strategy–associated divergence. Across all tissues, a total of 741 differentially expressed genes (DEGs) were identified between IVP and MOET groups. Across tissues, approximately 600,000 high-confidence transcriptome-derived variants were detected per tissue group, of these nearly 25,000 SNPs per tissue mapped to 741 identified DEGs, representing ~4% of the expressed variant pool and highlighting a focused subset of variants potentially contributing to transcriptional divergence. DEG-prioritized cis-eQTL analysis (within ± 500 kb of flanking region of each DEG) was implemented to investigate genotype–expression associations and to strengthen inference on functional regulatory variants. This study establishes a multi-tissue RNA-seq-derived SNP resource for bovine reproductive biology and identifies candidate functional regulatory variants orchestrating the physiological and metabolic differences between IVP and MOET calves.

Milk yield dynamics reflect health of dairy cows in early lactation

B. De Bruijn[1,2], I. Van Dixhoorn[2], B. Kemp[1], A. Van Knegsel[1]
[1] Wageningen University & Research, Adaptation Physiology group, De Elst 1, 6708 WD Wageningen, Netherlands, [2] Wageningen University & Research, Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, Netherlands

Dairy cows experience most health problems during early lactation, and these disorders can be associated with milk losses. Fluctuations in milk yield have been proposed as a valuable tool for health monitoring of dairy cows. The aim of this study was to investigate the relations between health status during the first 56 DIM and two types of milk yield dynamics: 1) lactation curve characteristics and 2) dynamic indicators of milk yield derived from deviations from the lactation curve. Data on daily milk yield and disease treatments of four previous experiments were combined and analysed. Cows were categorised in three ways based on disease treatments until 56 DIM: 1) health status groups: no health problem (NHP), systemic or inflammatory health problem (SHP), other health problem (OHP); 2) the number of disease treatments per cow (0, 1, or ≥ 2); and 3) the presence or absence of disease treatments for specific diseases including: mastitis, endometritis, claw and leg disorders, vaginal discharge or cystic ovaries. Lactation curve characteristics were calculated using the 5-day rolling average of daily milk yield and included peak production, day of peak production, slope to peak, total milk yield until 56 DIM, 305-d milk production and persistency. Dynamic indicators of milk yield, calculated from daily deviations in milk yield during 10-56 DIM and 10-305 DIM, included log-transformed variance (LnVar), lag-1 autocorrelation (Rauto), skewness and mean negative residuals (MNR). Mixed models were used to assess associations between disease treatments and milk yield dynamics. Peak production and total milk yield until 56 DIM were lower in SHP cows compared with NHP or OHP cows. Among cows of parity ≥ 3, SHP cows reached peak production later and had a lower slope to peak yield than NHP and OHP cows. Persistency and 305-d production were not affected by health status. Cows with health problems (SHP and OHP) during the first 56 DIM had a higher LnVar than cows without treatment for health problems (NHP). More specifically, cows treated for endometritis or cystic ovaries had a higher Rauto through lactation compared with healthy cows. The MNR during 10-56 DIM was lower for cows treated for claw and leg disorders compared with healthy cows, but MNR was not of added value for other treatments types or health groups, and neither was skewness. LnVar during 10-56 DIM was higher with increasing number of disease treatments. These findings indicate that cows with health problems in early lactation experience more milk yield perturbations than healthy cows, with responses depending on the type of disease and number of disease treatments in early lactation. In conclusion, while lactation curve characteristics specifically indicated cows with a systemic or inflammatory health problem, dynamic indicators of milk yield indicated both cows with a systemic or inflammatory health problem and cows with other health problems. Further research on disease-specific effects on milk yield dynamics may contribute to the development of on-farm health monitoring tools.

Liver hemorrhages and keel bone fractures in experimental cohorts of two high-performing laying hen strains from week 30 to week 42 of age

L. Ruda[1], L. Messmer[1], V. Sommerfeld[2], M. Rodehutscord[1,2], K. Huber[1]
[1] University of Hohenheim Institute of Animal Science, Functional Anatomy, Fruwirthstr. 35, 70599 Stuttgart, Germany, [2] University of Hohenheim Institute of Animal Science, Animal Nutrition, Emil Wolff Str.10, 70599 Stuttgart, Germany

Background Slaughterhouse studies revealed that liver hemorrhages and keel bone lesions commonly occur in high performing laying hens. Several risk factors associated with feeding, housing and production level have been identified. The present study aimed to describe the occurrence and the severity of these lesions in experimental cohorts of laying hens under standardized rearing, housing and feeding conditions. Methods The study comprised 438 hens (Lohman Selected Leghorn (LSL) n = 220; Lohmann Brown Classic (LB) n = 218) that had been reared under identical management, feeding and housing conditions in a free run indoor barn. Animals were slaughtered in four cohorts of 110 animals at 30, 34, 38 and 42 weeks of life. Three weeks before slaughter hens of the respective cohort were moved individually to metabolic units, equipped with a wooden perch, a nest, a feeding trough, water cups, and a wire mesh floor. In each cohort, 100 animals (LB n = 50; LSL n = 50) were fed a diet without mineral P supplementation (P_-) whilst ten animals, fed a diet with 1g/kg of mineral P (LB n = 5; LSL n = 5) served as controls (P_+). After opening, the abdominal cavity was inspected for bleeding before the liver was removed. Livers were photographed and the bleeding score, considering size and number of lesions, was assessed. A subset (P_-: LB n = 20, LSL n = 20; P_+: LB n = 5, LSL n = 5) was examined for keel bone fractures. Keel bones with adherent breast muscles were dissected from the carcass and examined by X ray. Fractures were scored using a visual analogous score. After maceration, keel bones were ashed. Data were analyzed in a three-factorial analysis of variance including strain, diet and age. Results Out of 438 animals, 9% showed no bleeding lesion in the liver, 66% had a score of 1 (< 10 lesions > 0.8 cm) and 25% (20% LB; 5% LSL) had a bleeding score of 2 (> 10 lesions > 0.8 cm) or higher. Strain exerted a significant effect leading to higher scores in LB than in LSL hens. Concerning keel bone fractures, 28% of the examined animals displayed a fracture score of 0, 36% a score of 1 and 36% a score of 2 and higher up to 4 (4%). Fracture severity was significantly higher in week 42 than in week 30. Omission of mineral P led to higher scores in LB but not in LSL hens. Cohort and diet significantly affected ash content. Ash content of keel bones was lowest in week 34 and highest in week 38. Controls consistently showed higher ash content than animals without mineral P supply. Ash content was negatively correlated with fracture score ($\rho = -0.27$) Conclusions The present study confirms the high prevalences of liver hemorrhages and keel bone fractures that are currently reported in commercial laying hens for the experimental cohorts studied herein, too. Strain exerted a significant effect on both scores, but lesions occurred in both strains. Thus, differences rather concerned severity than general occurrence of these lesions. Regarding fracture scores it must be considered that callus formation and mineralization occur two to six weeks after the preceding insult, implying that fractures might have been already present, when P_- diet was applied. Additionally, increasing scores over time might point to recurrent insults over time cumulating in week 42. Low correlation between ash content and keel bone fracture score further implies pathogenic mechanisms beyond bone mineralization.

Different motility of frozen semen between Holstein and Jersey bulls under heat stressed condition

S. W. Kim[1], J. Lee[1], G. Ryu[1], H. Baek[1,2]
[1] National Institute of Animal Science, Dairy Science Division, Shingang 1-gil, Seonghwan-eup, 31000 Cheonan, South Korea, [2] Dairy Science Department, Chungnam National University, Daehak-ro 99, Yu-seong-gu, 34134 Daejeon, South Korea

The bull fertility was known to be affected by hot humid conditions that is caused by global temperature increase. The increased body's temperature of cow's internal reproductive organs could reduce the fertility of bull's semen. It has been reported that fertility of Jersey is higher than Holstein in summer time primarily due to better tolerance of heat stress. However, the longevity of spermatozoa under heat stress has been less studied. To test tolerance of dairy bulls spermatozoa under unfavourable conditions, 4~5 proven bull semen of each breed were tested motility with time course examination. The spematozoa with progressive motility were isolated by Percoll gradient and exposured to 37.5°C and 41.5°C in a humidifed incubator with 5% CO2. The sperm was evaluated after 0, 1, 3 and 6 hours of incubation. We have found that longevity of sperm of Jersey frozen bull is better than those of Holstein. A significant increase ($P<0.05$) in Jersey spermatozoa motility was detected at 1 hour in 41.5°C and 3 hours in 37.5°C. These data suggests that sperm of Jersey breed have tolerance to heat stress during fertilization.

Phenotypic characterization of milk-derived liver enzymes and their associations with production traits in Holstein cows

I. Drzaic[2], V. Brajkovic[2], N. Raguz[1], M. Oroz[1], M. Oroz[1], M. Shihabi[2], M. Didara[1], I. Curik[2], B. Lukic[1]
[1] Faculty of Agrobiotechnical Sciences Osijek, Department for Animal Production and Biotechnology, Vladimira Preloga 1, 31000 Osijek, Croatia, [2] Faculty of Agriculture, Department of Animal Science, Svetošimunska cesta 25, 10000 Zagreb, Croatia

Milk biochemical markers provide a non-invasive approach for monitoring metabolic and liver status in dairy cattle. Understanding their variability across farms and lactation stages is critical for identifying phenotypes suitable for predictive models and genome-wide association studies (GWAS) targeting genetic determinants of metabolic efficiency and production traits. This study quantified milk-derived liver enzyme activities and their relationships with production and lactation parameters in 648 Holstein cows from three commercial Croatian farms (farm 1 – n = 344; farm 2 – n = 179; farm 3 – n = 125). Activities of alanine aminotransferase (ALT), alkaline phosphatase (ALP), and gamma-glutamyl transferase (GGT) were measured from milk together with standard milk composition traits, days in lactation (DIM), parity, and daily milk yield. Due to highly skewed distributions, ALT and ALP activities were log-transformed prior to statistical analysis. Descriptive statistics, Pearson correlations, and linear regression models were used to evaluate associations among traits. Substantial variability in milk enzyme activities was observed, particularly for ALT and ALP. ALT concentrations ranged from 0.6 to 1583.8 U/L, while ALP values ranged from 12.5 to 4198.5 U/L. GGT ranged from 223 to 12997 U/L. High coefficients of variation indicated considerable biological heterogeneity among samples. Correlation analysis revealed a strong positive association between ALP and GGT ($r = 0.59$), while ALT showed only weak correlations with the other enzymes. Days in lactation was moderately to high correlated with ALP ($r = 0.60$), indicating increasing ALP activity during later lactation stages. Negative correlations were observed between milk yield and ALP ($r = -0.40$) and GGT ($r = -0.25$), indicating potential links between metabolic load and production performance. Regression models further confirmed significant effects ($p<0.001$) of farm, days in lactation, parity, and milk yield on variation in milk enzyme activities,with ALP displaying the strongest associations ($R^2 = 0.47$). Overall, the results indicate substantial variation in liver enzyme activity among farms and across lactation stages, with ALP showing the strongest relationship with physiological and production variables. These findings suggest that milk-derived liver enzyme activities are associated with lactation dynamics and production traits, highlighting their potential as easily accessible phenotypes for metabolic monitoring in dairy cattle. The generated dataset provides a valuable phenotypic resource for future genome-wide association studies aimed at identifying genetic determinants of milk-based metabolic biomarkers.

The effect of half dose of colostrum replacer on immunity, feed intake, nutrient digestibility, and performance of dairy calves

M. Ravanetti[1], A. Collura[1], G. Bonacini[2], C. Balbo[1], G. Esposito[1,3]
[1] University of Parma, Veterinary Science, Strada del Taglio, 10, 43126 Parma, Italy, [2] Carra Mangimi, Via Alessandrini,4, 43058 Sorbolo (PR), Italy, [3] Stellenbosch University, Faculty of AgriSciences, Department of Animal Sciences, Matieland, 76200 Stellenbosch, South Africa

The aim of the study was to evaluate the efficacy of half dose of commercial colostrum replacer, as replacement of maternal colostrum, in newborn calves under different management conditions. The study has been conducted in two dairy farms where the calves were housed in individual pen with hutches with pelleted straw as bedding (farm1) or in individual cages with straw bedding (farm2). Furthermore, in farm1 calves were fed milk replacer by nipple buckets, whereas, in farm2, calves were feed milk replacer through individual automatic feeders. In both farms, the calves, blocked by birth weight, were immediately removed from the dams after birth and randomly allocated to one of the two experimental groups which received, within 3h from birth, either maternal colostrum (4l with ≥25°Brix via stomach tube, MC; n =30 in farm1; n =15 in farm2) or half dose of colostrum replacer providing 50g of IgG (4l via stomach tube, CR; n =30 farm1; n =15 farm2). In farm1, all the calves received a second meal of transition milk within 12h from the first meal. In farm2, only MC calves received a second meal of transition milk. The colostrum was analyzed for total bacterial count and E.coli. Blood samples were collected at birth and at 48h of life to estimate Apparent IgG efficiency of absorption (AEA). Following, blood samples were collected at 7 days of life and weekly thereafter until day 49. Daily, intake was recorded and calves monitored. Weekly, from birth to weaning (62±8 days), clinical evaluation, body weight, fecal score and bovine respiratory syndrome (BRD) score were recorded. Fecal and feed samples were collected every two weeks to assess nutrient digestibility. Average daily gain and nutrient digestibility were analyzed with ANOVA using the GLIMIX procedure; AEAI gG was analyzed, in Farm2 calves, by ANOVA using PROCGLM; all the other data were analyzed with ANOVA for repeated measures using the PROCMIX procedure. As expected, calves fed MC resulted in higher serum IgG levels compared to the CR fed calves ($P \leq 0.01$) at 48h of life. Furthermore, AEA IgG, measured in Farm2, resulted to be significantly lower in the CR group compared to the MC group ($P \leq 0.05$). However, only a trend for lower serum IgG levels was observed in the CR group over time with calves showing similar performance and health status. Furthermore, intake and nutrient digestibility didn't differ between groups. However, growth and performance were not affected. In conclusion, half dose of CR may be considered a valid replacement of maternal colostrum.

Association between passive immunity status on disease incidence and therapeutic interventions in dairy calves

J. V. Santos E Silva Mesquita[1], J. B. Daniel[1], J. Echeverry-Múnera[1], K. Iakhiaeva[1], D. R. Martinez Mayorga[1], J. Martín-Tereso[1], J. N. Wilms[1]
[1] Trouw Nutrition, R&D, Veerstraat 38, 5831 JN Boxmeer, Netherlands

Transfer of passive immunity (TPI), achieved through colostrum intake and immunoglobulin (Ig) absorption, is critical for reducing morbidity and minimizing subsequent medication use in dairy calves. This study evaluated the correlation between serum IgG concentrations after birth and the occurrence of therapeutic interventions and disease incidence in dairy calves. This dataset included 1180 Holstein male calves, collected from dairy farms between 24-96 h after birth. Guidelines for colostrum management at the farm of origin included 3 feedings of high-quality colostrum (>22% Brix) within the first 24h, starting with 3-4L 1h after birth, followed by 2 feedings of 2L. At arrival at the research facility, serum IgG was measured within 24-96h after birth and categorized as: Poor (< 10 g/L), Fair (10.0 – 17.9 g/L), Good (18.0 – 24.9 g/L) and Excellent (≥25.0 g/L). Age at sampling was not included as covariates in the statistical model. General calf health was monitored daily. Diarrhea was defined as the presence of watery feces and visible clinical signs such as a dirty tail and dehydration. Diarrheic calves were treated with oral rehydration solutions and/or intravenous fluids. In severe cases, flunixin and/or trimethoprim-sulfadoxine were administered. A respiratory disorder was defined as a respiratory rate > 30 breaths per min, fever, and the presence of at least one additional clinical sign, such as coughing, nasal/eye discharge, or reddened mucosa, treated with oxytetracycline, florfenicol or tilmicosin in combination with meloxicam. Finally, cases of ear or navel infection, diphtheria and arthritis were treated with ampicillin trihydrate. Regardless of the underlying cause, fever was defined as a rectal temperature > 39.3 °C and treated with meloxicam. Time-to-treatment analyses were conducted using Cox proportional hazards regression (PROC PHREG, SAS). Multivariate logistic regression models (PROC LOGISTIC) were used to evaluate binary outcomes, risk factors, and disease cascade effects. Continuous variables were analysed using mixed-effects models (PROC MIXED). Serum IgG category was used as fixed effect. Compared to the Poor (n=96) group, Fair (n=490), Good (n=369), and Excellent (n=225) TPI reduced the hazard of respiratory disease (HR=0.62, 95% CI: 0.43-0.89, P=0.01; HR=0.53, 95% CI: 0.36-0.79, P<0.01; and HR=0.37, 95% CI: 0.24-0.58, P<0.01), fever (HR=0.55, 95% CI: 0.40-0.76, P<0.01; HR=0.48, 95% CI: 0.34-0.68, P<0.01; and HR=0.44, 95% CI: 0.30-0.64, P<0.01), and antibiotic usage (HR=0.59, 95% CI: 0.43-0.81, P<0.01; HR=0.47, 95% CI: 0.34-0.66, P<0.01; and HR=0.38, 95% CI: 0.26-0.55, P<0.01). Overall morbidity was significantly lower in the Good (HR=0.69, 95% CI:0.51-0.94, P=0.02) and Excellent (HR=0.63, 95% CI:0.45-0.87, P<0.01) groups, whereas the Fair group only tended to have a reduction (HR=0.77, 95% CI:0.58-1.03, P=0.09) compared with Poor. Immunity status did not affect the hazard of receiving a treatment for diarrhea. However, calves previously treated for diarrhea had 2.28 times higher odds of developing a respiratory disease (95% CI: 1.71-3.04; P < 0.01). Calves in the Excellent group (2.61 d) had fewer treatment days compared to calves in Fair (3.19 d) and Poor groups (3.35 d; P=0.06). Serum IgG concentrations above 18.0 g/L were associated with a lower risk of overall morbidity in dairy calves, reduced incidence of respiratory disease and decreased need for antimicrobial treatments. Dairy farming practices should aim to achieve higher IgG concentrations, specifically ensuring calves fall within the Good classification, as a minimum management goal, while striving for Excellent.

Effect of incorporation a spray-dried fat concentrate containing tributyrin and tricaproin into milk replacer on the need for medical interventions in newborn calves.

K. Iakhiaeva[1,2], J. Echeverry-Múnera[1], J. B. Daniel[1], J. Martín-Tereso[1], J. Steinhoff-Wagner[2], M. Janssen[1], J. N. Wilms[1]

[1] Trouw Nutrition, R&D, Veerstraat 38, 5831 JN Boxmeer, Netherlands, [2] Technical University of Munich, TUM School of Life Sciences, Liesel-Beckmann-Str. 2, 85354 Freising-Weihenstephan, Germany

The presence of butyric (C4:0) and caproic acids (C6:0) in milk replacers (MR) is minimal or absent compared to bovine milk. The objective of this study was to evaluate the effect of inclusion of a spray-dried fat concentrate containing tributyrin and tricaproin as sources of C4:0 and C6:0 in MR on the need for medical interventions in newborn calves. This study analyzed data from 4 experiments conducted at the same facility, involving 138 Holstein male calves (2.2 ± 0.10 d of age; 45.5 ± 0.53 kg BW; 18.8 ± 0.72 g/L of serum IgG) collected from dairy farms. Calves were blocked by arrival sequence and within each block, calves were randomly assigned to either control MR (CON, n=69) or a MR containing tributyrin and tricaproin (TBTC, n=69). Milk replacers were iso-energetic with 23.8% protein, 27.5% fat, and 35.1% lactose (as product basis) and fed upon arrival. In 2 out of 4 experiments calves were group housed, fed MR ad libitum and monitored until d 84 and d 91. In the last 2 experiments calves were individually housed and fed MR twice daily until d 21 or d 35. Use of oral rehydration solution (ORS) was investigated separately from total medical treatments as it is considered a non-invasive supportive intervention. Medical interventions were analyzed using Cox proportional hazards regression (PROC PHREG in SAS) to estimate hazard ratios (HR) with 95% confidence intervals (CI). Continuous variables were analyzed using mixed-effects models in PROC MIXED. Treatment and block nested within experiment were included as fixed effects in both analyses to account for experimental heterogeneity while estimating a pooled treatment effect across experiments. Discrete variables were evaluated using a binomial logistic regression model (PROC GENMOD). The proportion of calves removed from the study due to mortality or severe health issues did not differ between TBTC and CON (2/69 vs. 4/69; P = 0.40). Calves fed TBTC had a 74% lower hazard of requiring any medical intervention compared with CON (HR = 0.26, 95% CI: 0.13-0.53; P < 0.01). Similarly, calves fed TBTC had a 68% lower hazard of receiving an antipyretic medication (HR = 0.32, 95% CI: 0.15-0.66; P < 0.01), a markedly lower hazard of receiving medical treatment for diarrhea, excluding ORS (1/69 vs. 8/69; HR = 0.01, 95% CI: 0.0004-0.32; P < 0.01), and a 88% lower hazard of antibiotic use compared to CON (HR = 0.12, 95% CI: 0.05-0.28; P < 0.01). Calves fed TBTC had 82% lower hazard of receiving at least one intervention for respiratory disorders (HR = 0.18, 95% CI: 0.08-0.42; P < 0.01) and 96% lower hazard of a second treatment for respiratory disorders than CON (2/69 vs. 10/69; HR = 0.04, 95% CI: 0.01-0.34; P < 0.01). No differences were observed in ORS use, either in the number of calves requiring ORS (P = 0.71), the hazard of ORS administration (HR = 1.01, 95% CI: 0.48-2.14; P = 0.98), or the number of ORS portions used per calf (P = 0.63). Calves fed TBTC required fewer days of medical treatment per calf than CON (0.63 vs 1.60 d; P = 0.01), including fewer days of intervention for respiratory disorders (0.21 vs 0.80 d; P < 0.01). Inclusion of tributyrin and tricaproin in MR reduced the incidence of health disorders and the need for medical interventions in newborn calves.

Digestive development and behavior in calves weaned on hay or concentrate diets

Young animals are often fed high-starch diets to enhance growth performance and gastrointestinal tract (GIT) development. However, this likely shifts the ruminal pH below the physiological range, possibly affecting rumen development. We hypothesized that a high-starch diet in the initial weeks of life would significantly influence feed intake, behavior, growth performance, and digestive development. We randomly allocated 48 newborn male calves to 2 treatments and fed milk replacer with ad libitum access to either chopped hay (HAY; crude protein 18.2%, NDF 41.9% and stach 1.96% dry matter) or a high-starch diet (STARCH; CP 18.0%, NDF 23.1% and starch 40.3% DM) for 10 weeks. In the last week, feed intake, digestibility and retention time were measured on a subset (n = 7/treatment). Afterwards, these animals were slaughtered for gross measurements and sample collection. Animals were continuously video recorded during the entire experiment and one day in weeks 2, 7, 10 of the study was selected for detailed behavior analysis. Groups were compared using mixed models that accounted for individuals and calf batch for repeated measures, and only for batch as a random effect in single measures. Body mass and solid feed intake increased significantly over time but did not differ between groups (all calves). In the subset of selected calves, at similar dry matter intake, STARCH showed higher dry matter and protein digestibility ($P < 0.01$) but lower NDF intake and NDF digestibility ($P < 0.01$). STARCH had longer mean retention times for fluid ($P = 0.04$), small particle ($P < 0.01$) and large particle marker ($P < 0.01$), and greater mean particle size of feces ($P < 0.01$). HAY had greater proportions of fine particles (<0.25mm, $P < 0.01$). The proportion of the finest fraction was higher in HAY ($P < 0.01$). At slaughter, there was no body mass difference between the groups, but a heavier carcass weight in STARCH ($P = 0.04$). STARCH had higher tissue mass for the caecum, jejunum, and total small intestine ($P < 0.01$; $P = 0.04$; $P = 0.02$), but not different for rumen. Although the total short-chain fatty acid amount did not differ, the rumen propionate and butyrate proportions in STARCH were higher ($P < 0.01$, $P = 0.02$) at the expenses of acetate. The pH of rumen, abomasum and caecum contents were higher in HAY ($P < 0.01$; $P = 0.04$ and $P < 0.01$). The spleens of STARCH were larger ($P < 0.01$). For behavior(all calves), animals in the HAY group spent more time on eating and ruminating, with a corresponding reduction in resting time. Conversely, the STARCH group exhibited increased stereotypic behavior and bedding consumption. These results indicate that early life high-starch diet need not be advantageous in terms of growth and GIT development if high-quality forage is available, and that high-starch diet has the expected effects on digestibility, rumen fermentation and behavior. Whether the low rumen pH in first weeks of life is detrimental for animal health, especially later in life, will be assessed in the older animals from this experiment. The absolutely and relatively larger spleens of the STARCH group may suggest a higher immunological challenge, though confirmation with immune markers is needed. Effects of calf dry TMR and warm-air-dried hay as sole solid feed on growth and behavior of pre-weaned calves

J. J. Hayer[3], F. Leixner[3], G. Hellmann[2], T. Scheu[3], C. Koch[1], G. Dusel[1], J. Stracke[2]
[1] University of Applied Sciences Bingen, Department of Agriculture, Animal Nutrition and Health, Berlinstraße 19, 55411 Bingen am Rhein, Germany, [2] University of Bonn, Institute of Animal Science, Farm Animal Ethology, Endenicher Allee 15, 53115 Bonn, Germany, [3] Educational and Research Centre for Animal Husbandry, Hofgut Neumühle, Neumühle 1, 67728 Münchweiler an der Alsenz, Germany

Solid feed intake is essential for early rumen development in calves. Calf dry total mixed rations (TMR), typically consisting of concentrate and chopped straw, are commonly used as the sole solid feed for unweaned dairy calves on German farms. Hay could represent an alternative feed source but typically contains less energy and protein. Warm-air-dried hay has high sugar content and improved digestibility and may represent an on-farm alternative to calf dry TMR. Furthermore, previous studies report increased rumination and reduced cross-sucking in calves offered hay.This study evaluated warm-air-dried hay as an alternative to calf dry TMR for feeding pre-weaned calves, focusing on growth, performance, and behavior.24 Fleckvieh calves were purchased at auction and transported to the experimental facilities of the Hofgut Neumühle on the same day. Calves had an average age of 32.1 ± 6.7 days and a body weight of 86.2 ± 3.2 kg. Calves were randomly assigned to two weight-balanced groups (n = 12) housed in identical barns. One group received warm-air-dried hay throughout the experimental period (HAY), while the second group received a conventional calf dry TMR (TMR-G), which was weighed and replaced daily. No other solid feed was provided.Calves received 10 L of milk replacer per day (140 g/L) via an automatic feeding station for four weeks. From week four onward, milk allowance was gradually reduced over four weeks until calves were weaned in week eight, followed by two weeks of monitoring. Growth was assessed weekly by body weight and body measurements (e.g., body length). Calf behavior was recorded, capturing 8 hours (08:00–16:00) on two days per week. Behavior was analyzed using BORIS Software and an ethogram comprising 15 behaviors. Three focal animals per treatment were selected for detailed behavioral analysis in addition to scan sampling of both groups. Animal behavior, development data, and feed intake were analyzed using separate generalized linear models.Calves fed TMR consumed more solid feed dry matter (1.1 kg/d) compared with calves fed hay (0.8 kg/d). Accordingly, the intake of metabolizable energy and utilizable crude protein (nXP) was higher in TMR-G than in HAY (12.9 vs. 9.01 MJ ME; 191 g vs. 124 g), with significant differences observed during the final two weeks of the trial. Milk replacer intake differed only on day 20 of the trial, with higher intake in HAY compared to TMR-G. Body weight was numerically higher in TMR-G during the final two weeks but did not differ significantly between treatments. Body measurements only differed in greater body length in TMR-G on day 4 of the trial. Behavioral analyses showed that calves in HAY spent significantly more time feeding and ruminating compared to calves in TMR-G. In contrast, calves in TMR-G spent significantly more time lying and exploring their environment. Although tongue rolling was only rarely observed, it occurred significantly more often in TMR-G than in HAY.Overall, the results indicate that warm-air-dried hay can serve as an adequate sole solid feed during the early weeks of the rearing period but does not sufficiently meet energy and protein requirements during the weaning phase, when nutritional dependence on solid feed increases. Furthermore, the type of solid feed influenced calf behavior, with mixed effects regarding the relative advantages of hay and calf dry TMR.

Factors influencing voluntary free water intake of Holstein calves with high milk replacer allowance and slow, late weaning

C. S. Ostendorf[1], J. Steinhoff-Wagner[1,2], K. J. Hemmert[3], F. Leixner[4], C. Koch[5], M. H. Ghafarri[6]
[1] TUM School of Life Sciences, Professorship of Animal Nutrition and Metabolism, Liesel-Beckmann-Straße, 85354 Freising, Germany, [2] Technical University of Munich, HEF World Agricultural Systems Centre, Liesel-Beckmann-Straße, 85354 Freising, Germany, [3] University of Bonn, Institute of Animal Science, Katzenburgweg, 53115 Bonn, Germany, [4] Educational and Research Centre for Animal Husbandry, Hofgut Neumühle, Neumühle, 67728 Münchweiler/Alsenz, Germany, [5] University of Applied Sciences Bingen, Professorship of Feedstuff and Feed Conservation, Berlinstraße, 55411 Bingen, Germany, [6] Research Institute for Farm Animal Biology, Wilhelm-Stahl-Allee, 18196 Dummerstorf, Germany

The current notion is that free water intake reflects a physiological integration of osmotic load, rumen activity, thermoregulation, and milk dilution effects, rather than being solely triggered by weaning onset. The aim of this study was to retrospectively analyze the water expense (WE; water use in L after automatic detection of a calf in the water station, WS) of 30 Holstein-Friesian calves (20 female, 10 male) fed a high milk allowance until d 56 and then gradually weaned until d 98. Calves were reared in three seasonal batches, with weaning between November to January (n=11), March to May (n=10), and April to June (n=9). All calves received 4 L colostrum and 12 L/d of MR until weaning. Concentrate (CON), hay, and water were offered ad libitum. Water temperature was < 10°C during the first weaning period and > 20°C during the second and third. Data were analyzed using R-Studio with a linear mixed model, including pattern and age as fixed effects and seasonal batch as a cofactor. Batch effects were tested with the partR2package by comparing the partial R^2 of batch and pattern, as well as by including their interaction in the model. First WE was defined as the first WE in the WS exceeding 0.1 L for at least two consecutive days. To examine its relation to the weaning process, calves were assigned to three behavioral patterns based on when first WE occurred relative to the weaning timeframe. In 5 calves, first WE was recorded before the onset of weaning (”BEF”, d 28 to d 56); in 15 calves, during the onset of weaning (“DUR”, d 59 to d 77); and in 10 calves at the end of weaning (“LAT”, d 81 to d 93). BEF calves may exhibit increased exploratory behavior, indicated by visits to the WS at a younger age (wk 4 ± 0.04 in BEF, wk 5 ± 0.07 in DUR and LAT, P = 0.007). Age at first WE coincided with overall number of visits to the WS/d (P < 0.001) as well as visits with WE per day (P < 0.001), with the highest values in BEF and the lowest in LAT calves. An earlier WE corresponded with a higher WE per day and per visit (P < 0.001). MR intake did not differ (P = 0.214), while LAT calves were associated with higher CON intake (P < 0.001). Feeding behavior did not differ among calves. The three seasonal batches were a significant cofactor in all models. The variance explained by batches was greater than by behavioral patterns (partial R^2= 0.09 and partial R^2= 0.01, respectively), in addition to an interaction between batch and pattern (P < 0.001), suggesting a batch effect due to the different seasonal batches. The winter batch had the first WE at the highest age and the lowest WE, per day (P = 0.002) and per visit (P = 0.008). The CON intake in the winter batch was higher than in the other two (P = 0.002). No behavioral pattern in feed intake can be linked to the onset of free water intake, and the behavior seems to be highly individual in well fed calves. Continuous access to drinking water is necessary even with high milk allowance, as water intake is not uniformly synchronized with weaning but reflects individual developmental paths.

Motivation of dairy cows to access food diversity in an operant conditioning task

L. Herve[1], R. Delagarde[1], A. Favreau-Peigné[2,3], C. Ginane[4]
[1] 1PEGASE, INRAE, Institut Agro, 16, Le Clos, 35560 Saint-Gilles, France, [2] Université Paris-Saclay, UVSQ, INRAE, BREED, 78350 Jouy-en-Josas, France, [3] Ecole Nationale Vétérinaire d'Alfort, BREED, 94700 Maisons-Alfort, France, [4] Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, F-63122 Saint-Genès-Champanelle, France

When given the opportunity, dairy cows choose to eat a diverse diet. However, in conventional systems, they are mainly fed with total mixed rations (TMR). This kind of diet may not meet their behavioural needs since it is poorly diversified, monotonous and do not allow them to perform their natural behaviour of feeding choices. In order to determine the importance of food diversity from the dairy cows' perspective, this study aimed to evaluate the motivation of 24 dairy cows to access food diversity, depending on whether they have been accustomed to a diverse diet or not. To do so, half of the cows was submitted to a period of food diversity for 29 d: they were fed with their usual TMR and two hays of contrasted nutritional values (regrowth of fescue and 1st cut of permanent pasture) offered separately. The other half was fed exclusively with the TMR. All cows performed two sessions of an operant conditioning test (15 d before and 15 d after the food diversity period). During the 10-min test, they could choose to eat their usual TMR freely available or walk across the 16 m U-turn test area to access two different foods of contrasted nutritional values (beet pulp pellets and permanent pasture hay) offered in limited quantities each time they completed a turn. During the first session, the cows only walked 0.28 ± 0.09 turn, chose to eat a large amount of TMR (4.0 ± 0.2 kg) and few diversified foods (no beet pulp and 15 ± 3.6 g of hay), showing that they preferred the TMR and were not motivated to access the diversified foods. During the second session, whether they had been accustomed to a diverse diet or not, the cows also chose not to provide the effort to walk to access the diversified foods. They walked 0.23 ± 0.08 turn and ate 3.9 ± 0.2 kg of TMR, no beet pulp and 13 ± 4.1 g of hay. Our results suggest that, under our experimental conditions, the effort required to access the diversified foods was probably too high in relation to the benefits derived from these foods, which could have been considered insufficiently rewarding. Moreover, habituation to a diverse diet did not affect the cows' motivation to access the diversified foods. These results would need to be confirmed under other experimental conditions (with other food rewards and/or effort of lower intensity).

Enhancing mineral bioavailability, stress resilience and welfare using magnesium phosphate: evidence from in vitro models and swine in vivo trials

B. Ribeiro[1], A. Lecointe[1], E. Dupuis[2], M. Brunon[3], J. Le Douce[3], E. Pagot[3], E. Coudert[2], A. Juanchich[2]
[1] PHOSPHEA, 27 avenue Franklin Roosevelt, 35400 Saint-Malo, France, [2] Centre Mondial de l'Innovation Roullier, 18 avenue Franklin Roosevelt, 35400 Saint-Malo, France, [3] INNÔZH, 2 rue Jean Rostand, 22440 Ploufragan, France

Context.Magnesium (Mg) and Phosphorus (P) availability is essential in pig nutrition to support health, performance, and to reduce excretion. This study evaluated a magnesium phosphate source (MgP) in comparison with monocalcium phosphate combined with magnesium oxide (MCP+MgO), through in vitro and in vivo approaches. In vitro work assessed mineral solubilization, absorption, cell viability under stress, and modulation of key molecular pathways. In vivo trials examined MgP effects on tail biting, ear lesions, and scratches in piglets. Materials and Methods. In vitro, MgP was compared with an iso-P and iso-Mg inclusion of MCP+MgO. P and Mg solubilization were quantified using an in vitro digestion model, and absorption assessed with a Caco-2 uptake assay. Cell viability was evaluated under normal conditions and under heat (40 °C) or oxidative stress (1000 µM H_2O_2). Gene expression related to Mg transport, membrane integrity, and oxidative stress responses was quantified by qPCR. A minimum of four replicates was used per assay. Data were analyzed by ANOVA ($p<0.05$). In the first in vivo trial, 398 piglets (70 days old) were assigned to either a control diet (MCP+MgO) or an MgP diet (iso P, Mg, Ca). Tail lesions were scored from 0 to 3 on D0, D18, D33, D42, D67, and D81. Weights were recorded at D0, D42, and D81. Weight data were analyzed by ANOVA and lesion scores by Mann-Whitney test ($p<0.05$). In the second in vivo trial, 151 gestating sows, were assigned to either control (MCP+MgO) or treated groups (MgP+MCP). After farrowing, piglets were allocated into two groups, each group having half of the piglets from first sow group and half from the second. Piglets' ear lesions and scratches were assessed at D15 post-weaning. Data were analyzed by ANOVA ($p<0.05$). Results.MgP significantly increased in vitro Mg solubilization and absorption compared with MCP+MgO ($p<0.01$). Under normal, oxidative or heat stress conditions, MgP increased cell viability compared with MCP+MgO-treated cells ($p<0.05$), and showed greater antioxidant capacity ($p<0.01$). Under normal conditions, MgP upregulated TRPM6, SLC41A3, and CLDN1, indicating improved Mg transport and membrane integrity ($p<0.05$). It also modulated oxidative pathways by maintaining baseline GPX2 expression, while MCP+MgO induced its upregulation ($p<0.05$). Under oxidative stress, MgP decreased CAT and increased GPX2 expression, suggesting a propensity toward chronic antioxidant responses rather than the acute detoxification ($p<0.05$). In the first in vivo trial, MgP reduced tail-lesion scores throughout the study ($p < 0.05$), with an average 20% decrease and a 66% reduction in severe lesions (score 3). Average daily gain was also improved between D0 and D42 (795 g/d vs 755 g/d) for MgP group. In the second in vivo trial, piglets from treated sows showed fewer ear lesions (4% vs 8.4%, $p<0.001$) and a tendency toward fewer scratches ($p=0.07$). Treated piglets also showed reduced ear lesions (4.9% vs 7.7%, $p=0.01$). The lowest lesion rate was observed when both sows and piglets were treated, with a 2.9-fold reduction ($p<0.001$). Conclusion.In in vivo trials, MgP reduced tail biting and ear lesions while supporting performance. This effect may be associated with increased Mg bioavailability, enhancing its metabolic utilization and supporting its role in stress-related physiological pathways. These results identify MgP as a promising alternative to MCP+MgO for improving mineral utilization, stress resilience, and welfare in pig.

Influence of dietary tryptophan-to-lysine ratio and level of large neutral amino acids on performance, lesion scores and behaviours of weaned piglets

J. Glinubon[1,2,3], J. E. Bolhuis[2], A. J. M. Jansman[3], N. Kelderman[4], E. Bruininx[4], W. J. J. Gerrits[1]
[1] Animal Nutrition Group, Wageningen University & Research, Department of Animal Sciences, De Elst 1, 6708 WD Wageningen, Netherlands, [2] Adaptation Physiology Group, Wageningen University & Research, Department of Animal Sciences, De Elst 1, 6708 WD Wageningen, Netherlands, [3] Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, Netherlands, [4] De Heus, Animal Nutrition, Rubensstraat 175, 6717 VE Ede, Netherlands

Tryptophan (Trp) competes with other large neutral amino acids (LNAA) for transport across the blood–brain barrier. This can influence its availability in the brain for serotonin synthesis, thereby affecting pig behaviour and indirectly influencing growth through changes in appetite and stress regulation. We aimed to study the effect of dietary Trp level on behaviour and biting-related damage in weaned piglets fed diets with adequate or reduced LNAA levels. Post-weaning piglets (n=720) with intact tails were assigned to one of 10 dietary treatments in a 5×2 factorial design, varying in standardized ileal digestible (SID) Trp:Lys ratio (0.16, 0.20, 0.24, 0.28, and 0.32) and LNAA level (85% or 100% of CVB requirements), with 12 pens (6 piglets, balanced by sex) per treatment. Piglets were classified into body weight (BW) classes (light, medium, and heavy). Feeding the LNAA 100% diet increased average daily gain (ADG) and gain-to-feed ratio (G:F) compared to the LNAA 85% diet across all BW classes ($P<0.01$). A Trp x BW class interaction was found for G:F ($P<0.05$). Within BW classes, dietary Trp affected G:F in heavy piglets, whereas no effect was detected in light or medium piglets. The response of G:F to dietary Trp in heavy piglets was nonlinear, with the highest G:F was found at Trp 0.28, values being higher than for Trp 0.20 and 0.32. Percentage of time spent walking, standing, and sitting was lower in heavy than in light piglets ($P<0.05$). Piglets fed the LNAA 85% were more active than those fed the LNAA 100% diet ($P<0.05$). Lying-inactive behaviour was higher in piglets fed Trp 0.24 than in those fed Trp 0.16 ($P<0.05$) and was greatest in heavy piglets ($P<0.01$). Tail, ear, and skin damage increased over time ($P<0.01$). Additionally, a Trp×LNAA×BW class interaction was observed ($P<0.05$) for both tail damage severity and skin lesion score; however, no pairwise differences were detected after Tukey adjustment. Heavy piglets exhibited the highest skin lesion severity ($P<0.01$), while ear damage was lower in heavy than in medium piglets ($P<0.05$). Neither dietary Trp nor LNAA affected the frequency of tail and ear biting, although both behaviours increased from week 3 to week 5 ($P<0.01$). Aggressive behaviour decreased over time ($P<0.05$) and was lower in piglets fed Trp 0.24 and 0.28 than in those fed Trp 0.16 ($P<0.01$). Similar effects of Trp level were found for mounting at the feeder ($P<0.01$). Belly nosing was reduced in piglets fed Trp 0.20 and 0.24 compared to Trp 0.16 and 0.32 ($P<0.05$). Heavy piglets showed less ear biting and belly nosing than light and medium piglets ($P<0.05$). In conclusion, feeding weaned piglets with Trp levels relative to Lys of 0.24 – 0.28 improved feed efficiency in heavy piglets and increased lying behaviour while reducing aggression, belly nosing and feed competition behaviour, regardless of LNAA supply. The response to the Trp:Lys ratio was non-linear; both deficiency (0.16) and excess (0.32) produced more undesirable behavioural. Tail and skin damage were affected by a Trp×LNAA×BW class interaction, with no clear pattern. Moreover, adequate dietary LNAA improved growth performance and increased lying behaviour across all BW classes.

Comparison of two commercial 6-phytases on growth performance in a dose response trial with weaned Piglets

R. Khurana[1], X. Guan[2], V. Lagos[2], M. Schmidt[1], R. Janßen[1]
[1] Kaesler Nutrition GmbH, Zeppelinstr. 3, 27472 Cuxhaven, Germany, [2] Schothorst Feed Research, B.V., Meerkoetenweg 26,, 8218 NA Lelystad,, Netherlands

Phytases are widely used in piglet nutrition to enhance the digestibility of phytate-bound phosphorus (P) and calcium (Ca), supporting growth while reducing inorganic P excretion. This study evaluated the dose–response efficacy of two commercially available 6-phytases on growth performance and apparent total tract digestibility (ATTD) of Ca and P in weaned piglets. A total of 384 piglets (Tempo × TN70; 29 days of age; 8.5 ± 1.05 kg BW) were assigned to eight treatments: a P-deficient negative control (NC), a P-adequate positive control (PC), and six NC-based diets supplemented with 250, 500, or 1000 FTU/kg of either product A or product B. Both products are registered with EFSA and are produced by genetically modified strains of Komagataella and Aspergillus oryzae for products A and B, respectively. Experimental diets in pelleted form were fed from day 8 to 35 post-weaning. Growth performance was monitored throughout the study, and pen faecal samples collected from days 22–25 were analysed for ATTD of P and Ca. Statistical analysis was conducted using GenStat® for windows (23rd edition). Across all performance parameters, no significant differences were observed between products at any of the inclusion levels. During days 8–22, product A at 500 FTU/kg (486 g/day) improved ($P<0.05$) ADG by 14.6% compared to NC (424 g/day). For the overall period (days 8–35), PC improved ($P<0.05$) the ADG and feed conversion ratio (FCR) compared to the NC (562 g/day vs. 483 g/day; 1.33 vs. 1.45 respectively). Product A and B at 500 and 1000 FTU/kg also improved ($P<0.05$) ADG compared to the NC (575 and 561 g/day for product A; 553 and 555 g/day for product B). The FCR of piglets fed Product A at both 500 and 1000 FTU/kg and product B at 1000 FTU/kg did not differ from the PC group. Both phytases improved ($P<0.05$) mineral digestibility in a dose-dependent manner. Further, the faecal score during the period days 22-35 improved ($P<0.05$) with increasing phytase doses. Dose–response modelling for ATTD of Ca and P demonstrated strong linear relationships for both phytases, supporting a consistent dose-response relationship (R^2= 62% to 91%, for Ca and P respectively). In conclusion, both 6-phytase products were effective in hydrolysing phytate-P and improve growth performance and mineral digestibility in a wheat-barley-soybean meal-based NC diet, particularly at the dose of and above 500 FTU /kg.

Effects of Early-Lay Prebiotic Supplementation with Galacto-oligosaccharides on Severe Feather Pecking and Associated Feather Damage in Laying Hens

During severe feather pecking (SFP), one hen repeatedly pecks or pulls the feathers of another, leading to feather damage (FD), increased risk of injury and pain, and impaired thermoregulation and locomotion. These effects compromise welfare, health, and productivity. Potent stressors, like the loss of social and environmental familiarity, can promote frustration and SFP. This can occur during the transition from rearing to laying barns, which involves transport, remixing of groups, and adaptation to new pens. In birds, preening and pecking can also socially transmit chemicals and microbes via feathers, potentially shaping social interactions. Disturbances of the microbiota-gut-brain axis have also been linked to SFP. Prebiotics, like galacto-oligosaccharides (GOS), can increase the growth of beneficial bacterial taxa in the gut and could serve as preventative tools to enhance birds' capacity to cope with subsequent stressors. This study tested if preventative GOS could reduce SFP and FD during subsequent periods of social mixing and adaptation to new pens. White Leghorn laying hens (N=144) from genetic lines selected for high or low FP activity were housed in 12 floor pens with equal line representation and observed for FP and FD during a baseline period (18-19 weeks of age; woa). During the supplementation period (19-22 woa), six pens (GOS) received water supplemented with Nutrabiotic® GOS (74% GOS; Dairy Crest Limited, Davidstow, United Kingdom), and six received plain water (control). This was followed by a stress period (23-26 woa) where half the GOS and control pens underwent repeated mixing of unfamiliar hens and were moved to new pens (stressed), while the others remained undisturbed (undisturbed). SFP was analyzed from videos as average pecks per pen. FD was scored (0-2) by a blinded observer at the end of each period. A generalized linear mixed model (SAS) with a lognormal distribution was used to evaluate the effects of supplementation and stress on SFP during each period. Behaviour during the baseline period served as a covariate and pen was fitted as a random effect. FD was analyzed with multinomial models reporting odds ratios (OR and 95% confidence interval (CI)) for worse damage. Preventative GOS supplementation did not change SFP rates during supplementation ($p = 0.3935$), or the subsequent stress period ($p = 0.2783$). However, GOS hens were more likely to have worse FD during the supplementation period than control hens (OR=2.20, 1.08-4.49). During the stress period, both undisturbed GOS hens (OR=3.96, 1.47-10.70) and stressed GOS hens (OR=2.92, 1.08-7.89) were significantly more likely to have worse feather cover damage than undisturbed control hens. Based on these results, we propose two explanations: 1) a sensory/social transmission pathway, where GOS and its galactose-containing residues on beaks and feathers reinforce early pecking and 2) a reward-loss frustration pathway where withdrawal of the preferred GOS at stress onset redirects pecking. This interpretation aligns with evidence that hens can detect galactose and exhibit preference-driven intake responses to it, and highlights new opportunities for hypothesis-driven work on feeding strategies to optimise welfare.

Location Matters: Impact of Pecking Block Placement on Feather Condition in Laying Hens

E. Simmonds[1], A. L. Nicklas[1], N. Van Staaveren[1], T. Widowski[1], A. Harlander[1]
[1] University of Guelph, Animal Biosciences, 50 Stone Road East, N1G2W1 Guelph, Canada

Feather pecking (FP) in chickens is the act of pecking and/or pulling at the feathers of conspecifics, often leading to feather damage (FD) and reduced welfare. FP is widely believed to be a form of redirected foraging behaviour as under natural conditions, chickens forage on the ground and peck upwards to consume berries from bushes. However, in commercial environments chickens are housed at high stocking densities and food is generally provided at ground level, increasing the likelihood that upward pecking behaviour is redirected towards the feathers of other birds. Introducing elevated pecking blocks (PB) as edible enrichment has the potential to redirect FP away from conspecifics and towards the blocks. This study aims to investigate whether elevating PB could redirect attention upwards and influence the onset and progression of FP behaviour, feather cover scores, and PB usage. A total of 364 1-day-old chicks from two commercial strains were assigned to one of three treatments: access to hanging PB, ground PB, or no PB (n=4 pens/treatment). Feather cover damage was scored by blinded observers across four regions (head/neck, back, tail, and belly) and the worst feather score per bird (0=no damage, 1=minimal damage, 2=severe damage) was used for statistical analysis. A multinomial model with odds ratios (SAS V9.5) was used to analyze the effect of treatment on FD where an OR > 1 indicates higher odds of worse FD. All birds exhibited intact feather cover at 17 weeks of age (WOA). At 30 WOA, 73.1% of birds retained intact feather cover, while 18.6% and 8.3% showed minimal and severe FD, respectively. At 45 WOA, feather condition declined across treatments, with 41.8% of hens maintaining intact feather cover with the rest of the birds displaying minimal (30.8%) and severe (27.4%) FD. Multinominal modeling assessing the odds of receiving the worst FD score indicated no differences between control and ground PB treatments, at any age. At 45 WOA, hens provided with ground PB had significantly greater odds of receiving the worst feather damage score compared to no PB (OR = 1.69, 95% CI: 1.06–2.70, p = 0.027), indicating a higher likelihood of severe feather damage in the ground PB treatment. In summary, feather cover declined with age across all treatments, highlighting a general welfare concern; however, differences among enrichment placements were minimal under the conditions of this study. Ongoing analyses will evaluate whether individual pecking block usage and behavioural observations, such as FP behaviour, correspond with FD outcomes and are influenced by the placement of PB, with findings interpreted in the context of scoring methodology, environmental factors, and the challenges of disentangling causes of feather loss in enriched research settings.

Impact of dietary amino acid supply on milk urea and urine nitrogen excretion and energy corrected milk of dairy cows fed hay-based diets

F. Righi[1], R. Pitino[1], E. Tsiplakou[2], M. Simoni[1]
[1] Università di Parma, Scienze Medico-Veterinarie, Via del Taglio, 10, 43126 Parma, Italy, [2] Agricultural University of Athens, Department of Animal Science, Iera Odos, 75, 11855 Athens, Greece

This study aims to investigate the impact of amino acids supply from hay-based diets on lactating dairy cows (LC) N excretion and energy corrected milk ECM (lNEx or hNEx). Twenty herds (184±89 cows; 178±19 DIM; 678±33 BW) were enrolled in the study. Feed intake was measured in each farm during 2 consecutive days by difference between the TMR offered and refused. Urine samples were collected twice from 10% of the LC. Milk yield was recorded, and 2 bulk milk samples were collected at 12h intervals. The BW was measured on 20% of the LC. The urinary creatinine content was determined through the Jaffe colorimetric method and used to calculate urinary output. Urine nitrogen (UN) and Milk Urea Nitrogen (MUN) were determined by Dumas and Milkoscan respectively and summed for NEx calculation. The dietary aminoacid (AA) content was estimated using the internal standard method (Trp), and an external calibration curve (all other AA) after analysis of the samples through RP-UPLC/ESI-MS in the SIR scan mode. The herds were categorized as low or high NI (<600, 601 to 650 and >650 g/d respectively) and, within each intake category, as lNEx or hNEx (respectively the lower and higher 50% of the data). The NEx was reduced by the increase of dietary serine (y = -100.29x +530.46; R_2=0.155), threonine (y = -113.63x+529.88; R_2=0.148) and tyrosine (y = -70.137x+360.95; R_2=0.127), while it was increased by the increment of dietary lysine (y = 66.179x+104.15, R_2=0.178). The ECM was increased when dietary arginine increased from 2.5 to 4.0 g/MCal (y=2.0579x+26.819; R_2=0.130). The lNEx herds received higher content of Met (0.26±0.03 vs 0.24±0.02% DM; P=0.040) and Ser (0.66±0.07 vs 0.61±0.04% DM; P=0.034), and a trend for a higher content of Ala (0.067±0.04 vs 0.64±0.05% DM; P=0.058), Thr (0.57±0.06 vs 0.54±0.03% DM; P=0.090), and total AA (12.08±0.87 vs 11.40±1.01% DM; P=0.061). These differences disappeared when the amount of amino acids administered were expressed on an energy base (g/Mcal). The NEx from LC fed hay-based diets seems to be reduced by the administration of specific amino acids and the role of dietary energy should be considered in modulating NEx. Whole plant vetch silage as roughage for growing pigs: Effects on growth performance, slaughter characteristics and outdoor run use

S. Witten[1], J. Wiskandt[1], M. T. Machner[1], R. Bussemas[1], K. Aulrich[1]
[1] Johann Heinrich von Thünen Institute, Institute of Organic Farming, Trenthorst 32, 23847 Westerau, Germany

Roughage production can contribute to soil and crop health in circular agricultural systems, and improve the resilience of systems with pig husbandry by providing opportunities to conduct natural behavior, improving health, and contributing to the nutrient supply (reviewed by Klevenhusen et al. 2026). Vetch plants can be included in crop rotations as winter catch crops, effectively supplying nitrogen for the following crop, while providing a protein-rich roughage. The objective of the study was, to investigate if vetch whole plant silage can contribute to the nutrient-supply of growing pigs and enrich their husbandry conditions. In two trials (DEZ and MAY), 60 and 80 growing pigs ((Topigs Norsvin L-Line x Topigs Norsvin Z-Line) x PIC 408) born and raised on the experimental station of the Thünen Institute (certified according to EU regulation 2018/848), were fed a compound feed containing cereals and grain legumes harvested on the station. In addition to the compound feed for the growing and finishing phase, formulated to contain about 8.2 and 5.7 g standardized ileal digestible lysine and less than 176 and 134 g crude protein per kg dry matter, respectively, 20 pigs each per trial were supplied either with triticale straw (control = CON) or with 0.9 and 1.4 kg fresh whole plant vetch silage derived from Pannonian vetch (VP), common vetch (VS) or hairy vetch (VV, only in MAY) in the growing (<75 kg body mass) and finishing phase, respectively. The pigs were weighed weekly, and slaughtered when weighing at least 119 kg. Dressing percentage was calculated using the warm carcass mass and lean meat percentage was measured using FOM S89 (SFK systems, Copenhagen, Denmark). Retention time of the silage in the racks (every day) as well as use of the outdoor run (last two Wednesdays and Saturdays before first slaughter) were observed for CON, VS and VP using photographs that were automatically taken every 10 minutes (Dahua HDW1200, 2 MP; Dahua XVR5116H-X). Generalized linear mixed models were performed with R. Pigs in the silage groups had a 3-5 d shorter growing and 3-5 d shorter finishing phase as well as an improved compound feed conversion in the finishing phase. Dressing percentage was between 79 and 80 % and lean meat percentage was 56.9 (CON), 57.7 (VS) and 58.2 (VP, VV). During daytime (DEZ 08:30–20:30; MAY 07:00–21:00) pigs of VP and VS were observed more often in the outdoor run and in front of the racks. While CON racks were never emptied, VP and VS groups failed to empty the racks on 6 and 7 days in MAY, respectively. On the other days, VP and VS groups emptied their racks during 3.2 ± 0.65 h in MAY and 6.3 ± 3.34 h in DEZ and 2.5 ± 0.65 h in MAY and 6.6 ± 3.34 h in DEZ, respectively. Like alfalfa silage (Messinger et al. 2022), vetch silage can contribute to the nutrient supply and improve compound feed efficiency without decreasing carcass quality. Outdoor run use increases with providing grass or clover silage (Høøk Presto et al. 2009, Holinger et al. 2018, Höne et al. 2022). Vetch silage has the same effect. Overall, vetch whole plant silage is a suitable roughage for fattening pigs that can contribute to their nutrient supply while enriching their husbandry system. Betaine supplementation in adult goats exposed to heat stress conditions

F. J. Giráldez[1], A. Díaz Reyes[2], S. Bettini[3], M. Dehnavi[1], M. J. Ranilla[1,2], L. Abdennebi-Najar[4], S. Andrés[1]
[1] Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas s/n, 24346 Grulleros (León), Spain, [2] Universidad de León, Departamento de Producción Animal, Campus de Vegazana s/n, 24071 León, Spain, [3] Università degli Studi di Perugia, Department of Agricultural, Food and Environmental Sciences, Piazza dell'Università, 1, 06123 Perugia, Italy, [4] INSERM, UMRS 938, Centre de Recherche St Antoine, 75012 Paris, France

The MEDGOAT project (PRIMA 2022) addresses the need to adapt goat production systems to global warming in the Mediterranean countries, where animals are usually exposed to heat stress conditions, particularly during the summer season. Therefore, it is imperative to find strategies dedicated to improve the resilience of the animals against heat stress, thus improving health and welfare and also minimizing the loss of animal performance. There is scientific evidence that methionine requirements increase under heat stress conditions. In this sense, betaine, a choline derivative, is important because of its role in the donation of methyl groups to homocysteine to form methionine. Moreover, betaine also demonstrates interesting osmoregulatory properties that might help to mitigate the effects of water restriction. Consequently, our hypothesis was that betaine supplementation helps adult goats to cope with heat stress conditions during the summer season. Therefore, twelve Murciano-Granadina mature goats were divided into two groups of six animals each. The betaine group (BET, n=6) received at 09:30 a.m. every day 8 g of betaine in water solution (20 ml) using a drench gun to ensure a daily intake of approximately 0.2–0.3 g/kg BW, whereas the control group (CTRL, n=6) received daily 20 ml of water. All the animals were kept under pasture conditions (from 10:00 to 17:00, with no water or shadows available), then housed indoors (from 17:00 to 10:00) with free access to fresh water and a diet supplied ad libitum until the next day. The experiment lasted 15 days and animals spent 71% of their daily grazing time (12:00 to 17:00 h) within a Temperature Humidity Index (THI) range of 72 to 78 while exposed to direct solar radiation. Rectal temperature in adult goats increased after the grazing period, exhibiting the BET group a more consistent thermal accumulation, with an increment significantly higher (0.79 °C, p=0.02) than the expected 0.5 °C circadian threshold reported for goats under thermoneutral conditions. In contrast, the increment of rectal temperature in the control group was not significant (0.61 °C; p=0.22) relative to the circadian baseline. No effects on the live weight, biochemical profile, hemogram (including dehydration indicators such as hematocrit or erythrocytes) or ruminal fermentation parameters (including pH and volatile fatty acids profile) were found. Only numerically lower values of beta-hydroxybutyrate in the BET group (P=0.105, not significant) were detected, probably suggesting improved lipid metabolism in the liver. All these results point towards potential osmo-protective effects of betaine, which might have reduced the water evaporation needed to reduce body temperature, thus allowing an adaptative hyperthermia in the BET group. It must be considered, however, that heat stress conditions underwent by these adult goats were moderate/mild, and this would also explain the lack of dehydration observed in both groups. Consequently, further analysis (e.g., expression of genes encoding heat shock proteins) are needed to verify the protective effects of betaine under heat stress conditions.

Effects of live and inactivated yeasts on ruminal pH and redox potential (Eh) in dairy cows under high-carbohydrate challenge
